SUPPLEMENT TO "THE ENGINEER," JANUARY 18, 1895

# The Engineer.

VOL. LXXVIII.—FROM JULY TO DECEMBER, 1894.

London:
OFFICE FOR PUBLICATION AND ADVERTISEMENTS, 33, NORFOLK STREET, STRAND, W.C.

THE ENGINEER.

## THE ANTWERP EXHIBITION.

### THE MARITIME SECTION.—I.

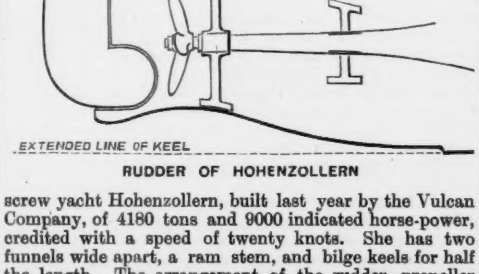
While shipping, shipbuilding, and cognate matters in the Antwerp Exhibition are, roughly speaking, contained within the "Maritime Section,"—as already stated in a recent issue—to which a very extensive portion of the main buildings are devoted, the bounds thus given to the domain of things maritime are very far from thoroughly embracing all the varied and important objects coming under the general category. Not a few highly-important exhibits connected with ships and with seafaring matters—such as the complete marine engines and propeller shown at work by the Société Cockerill, of Seraing, and the shafting, propellers, and other heavy items shown by other firms—are naturally relegated to the Halles des Machines, or Machinery in Motion Department. Similarly in the general section of the Exhibition occupied by Britain, Belgium, France, and Germany, whole stands—and numerous individual items—are to be found directly connected with shipping, while even in the outside grounds or in separate pavilions or annexes are objects intimately associated with the general subject, from the representation or fac-simile of the ancient Viking ship found in Norway, down to the diving operations on the most advanced modern principle exhibited in the pavilion of Messrs. Siebe, Gorman, and Co., of London.

Generally speaking, however, interest is pretty well centralised about the courts in the Hall of Industries section, where, under the conspicuous sky-sign spelling "Navigation," ship models and photographs, model marine engines, and small-scale models of docks and shipping-ports are congregated. While there is a good deal that must be already familiar to our readers, there is also much of novelty and interest attaching to by far the greater number of exhibits. The Clyde, the Tyne, the Wear, and other British centres of shipbuilding, are all well represented by beautiful models, photographs, &c., of ships, many of them of recent build or now being built. Where shipbuilding firms are not themselves exhibitors, their work is often to be found represented by the shipowners; very many of whom send splendid models—now usually supplied to them by builders as part of the contract. In not a few cases both shipbuilders and shipowners are found sending models of the same vessels; but as these are all of such exceptional interest as attaches to famous modern mail and passenger steamships, and as the models themselves are beautiful works of art, the redundancy is highly acceptable rather than otherwise. The principal ocean mail lines are fully represented, while, of course, an exhaustive and thoroughly representative show is made by the various companies engaging in Channel passenger service. The German, French, and Belgian mail steamship lines are especially well represented, and the same may be said of some of the continental shipbuilding and marine engineering firms. The efforts to secure attention, and subsequent patronage, put forth by such companies as the North German Lloyd, the Hamburg-American, the Red Star, and the International (American) Line, are of the most imposing and effective kind.

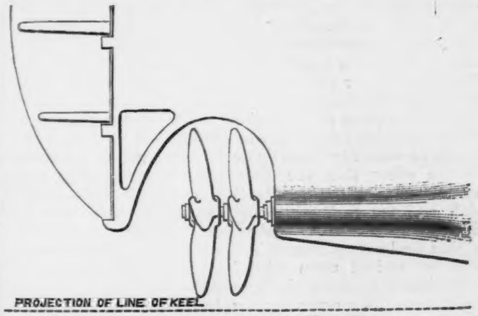
Advantage has been taken of the Exhibition by the Chambers of Commerce or Harbour Commissioners of almost all the well known continental shipping ports, to make known the importance of the shipping accommodation and the facilities for loading and unloading they can offer. Both by bird's-eye models of great minuteness of detail, and by pictorial representation, such ports as Hamburg, Antwerp, Dunkirk, Ghent, Copenhagen, &c., are very strikingly illustrated, and information given of interest and utility to all engaged in maritime industry; while Southampton, as well as the London and St. Katherine Docks, also the Royal Victoria and Royal Albert Docks, are similarly in evidence. In a subsequent article further attention will be directed to the matter of docks and shipping ports as here exemplified. Marine engineering and allied branches of industry, including, of course, steel manufactures, forgings, castings, &c., form no inconsiderable part of the machinery-in-motion section, and to some extent in the general sections of individual countries like Britain, France, Germany, Belgium, Holland, &c.; but the first-named country, considering its pre-eminence in these branches of industry, has but indifferently responded to the invitation of the Antwerp Exhibition promoters.

That the maritime section has been made the highly important section it undoubtedly is, is largely owing to the efforts of Mr. John P. Best, an Englishman resident in Antwerp, and the head of a most extensive shipping agency business in the city. His enterprise and energy, and his intimate knowledge of shipping and widespread connection, have served him well as director of the committee charged with collecting and organising the section, and the result amply testifies to these facts. The large space allotted to the section enables the stand or pavilion of each firm, and even of each individual exhibit—as in the case of large full models, in which the section is particularly rich—to be minutely and comfortably inspected. The want of a catalogue for this as for other sections, however, has made it difficult to take adequate or orderly note of all that is to be seen, or at least to make any very satisfactory attempt at dealing with exhibits according to their class or character. In the circumstances what is proposed to be done in this, and the articles immediately succeeding, is to describe the larger and more strikingly interesting stands as they occur in a walk through the section, and afterwards treat separate and more notable exhibits fully, and in a comparative way, as regards the several firms or countries producing the real ships, &c., they represent.

Occupying a large space, and a most commanding position in the centre of the main avenue, is a pavilion, approached on all sides by flights of steps, containing the exhibits made by the North German Lloyd Company, of Bremen, and by the Vulcan Shipbuilding and Marine Engineering Company, of Stettin, who have built several of the recent vessels of the North German Lloyd fleet. The two companies thus associated as exhibitors share the pavilion between them, and together they make one of the most superb displays of ship models and photographs, marine paintings, and articles of nautical equipment, we ever remember to have seen. The pavilion itself is a notable erection in white and gold, about 120ft. by 70ft., open-arched on all four sides, with Corinthian pillaring and massive balustrading partially screening the interior, and with coats of arms and emblematic figures worked into the ornamentation of the structure. Inside, the various models—all full ones in large glass cases—are most suitably disposed for all-round inspection, and the pleasure of this is enhanced by much soft carpets, luxurious lounges, cool green palms, and civil and obliging attention on the part of the ships' officers in charge. On the deep freize running round the upper part of the interior are well-executed paintings, representing ports, harbours, and scenes of note with which the company's fleet is associated; while at the Vulcan end of the pavilion the corresponding scenes represent views of the Vulcan Company's shipyard, quays, engine-works, &c.—all in themselves quite educational. In the centre of the German Lloyd end of the pavilion is a flat glass table exhibiting a chart of the world, with the various routes taken by the company's fleet pictorially delineated. Several of the models represent vessels which are already well known, while others are of steamers not yet launched. Of the former, we need only mention the s.s. Havel and Spree, Atlantic liners built in 1890 by the Vulcan Company; the s.s. Karlsruhe, engaged in the Australian service, built by the Fairfield Company; the H. H. Muir, in the South American service, built by Armstrong, Mitchell, and Co.; and the Kaiser Wilhelm II., in the Mediterranean and New York service, built in 1889 by the Vulcan Company. A striking exhibit is that of a model of the Kaiser's twin-screw yacht Hohenzollern, built last year by the Vulcan Company, of 4180 tons and 9000 indicated horse-power, credited with a speed of twenty knots. She has two funnels wide apart, a ram stem, and bilge keels for half the length. The arrangement of the rudder, propeller swelling and brackets, and the line of keel in their vicinity, are peculiar. A rough, hastily-taken hand sketch herewith may convey some idea of these features. A similarly rough hand sketch taken from the model is also given of the screw aperture and rudder of the twin s.s. Patria, now being built by the Vulcan Company for the Hamburg American Company. This vessel is 460ft. by 52ft. by 35ft.; is about 7600 tons gross, 4100 indicated horse-power, and is intended to travel at thirteen knots. The line of keel, it will be observed from the sketch, rises from the general level as it proceeds aft, and is arched over the propeller aperture, thence down to meet the bottom pintle of the rudder, thus having no "heel" or under connection whatever. The shafting of the propellers is housed in a swelling of the hull proper, and the propellers themselves are arranged one further ahead than the other, and the blades of the two overlap each other in revolving. What the idea of the designers may be for these several departures from what is most usual is not very apparent, the more so as what might stand as an explanation or *raison d'être* for one thing appears likely to be neutralised by another. Possible want of rigidity and liability to foul with sea wreckage would almost suggest themselves as contingencies attaching to the overhang of propellers and the open aperture adopted. This vital matter of screw propeller disposition and aperture seems to be made a study of by German builders, because in another of the models shown—that of the vessels Prinz Luitpold and Prinz Henreich, at present under construction in the yard of Herr Schicau, of Elbing, Prussia, for the German Lloyd's Australian and China service—the propeller blades also overlap each other; but they do so in an aperture of the ordinary kind. Remaining models in the pavilion, all shown by the Vulcan Company, are those of the German twin-screw cruising corvette Irene, of 8000-horse power and 18 knots, built in 1887; the Chinese cruisers, King Yuen and Lai Yuen, of 2900 tons displacement, 3400 indicated horse-power, and 15 knots, speed, and the German torpedo cruiser Comet—built last year—78m. in length, 9m. breadth, and 5·875 depth; 975 tons displacement, 5000 indicated horse-power. She is of razor-like fineness, and the 21 knots speed with which she is credited does not appear to be too high a rating of her capabilities in moderately calm states of the sea.



RUDDER OF HOHENZOLLERN



STERN FRAME OF PATRIA

The Hamburg-American Company's pavilion—not far off—occupies even a larger space than the German Lloyd's, but incorporated with the larger company's display are a great number of exhibits shown by various shipping concerns trading out of Hamburg, or forming extensions of the larger company's service. Roominess and luxuriance are also characteristics of the pavilion here, and the ottoman lounges provided constitute a rallying and seductive feature for the foot-weary wanderers through courts and avenues. A large and specially screened part of the pavilion contains an extensive series of moving dioramic views of the company's steamers, exteriors and interiors, and scenes associated with their arrival and departure from the several ports. These peep-show views are most excellent of their kind, and the twenty-five or more chairs in front of the moving pictures are constantly occupied by delighted spectators. The interior views—especially of the Fürst Bismark, the Normannia, and Augusta Victoria—give a very realistic impression of the superb accommodation provided on board. Notable among the full models occupying the floor are those of the twin s.s. Fürst Bismark, built by the Vulcan Company in 1891, of 8875 tons, 14,000 indicated horse-power, and 19½ knots speed, a striking feature of which is, besides her three funnels, the perfect forest of large ventilators to her machinery rooms; the twin s.s. Columbia, built by Messrs. Laird and Co., Birkenhead, in 1889, of 7363 tons, 13,500 indicated horse-power, trial speed 20 knots, average speed on best voyage 19·14 knots, and average speed on four voyages during 1889, 18·57 knots; the single s. s. Dania and Scandia, built by the Vulcan Company in 1889, 4050 tons, 3000 indicated horse-power, 13 knots speed; and the single s.s. Kanzler, built by Messrs. Blohm and Voss, of Hamburg, in 1892, of 3053 tons and 1600 indicated horse-power. A half model of one of the company's steamers, the Frisia—an elaborately finished sectional model showing all interior detail—and a model to a ¼in. scale of the company's graving dock, pump-house, &c., with the Frisia on the blocks, are two other objects worthy of mention. Messrs. Blohm and Voss are represented by a collection of half models of their largest productions, including the s.s. Stassfont of 340ft. in length, and the twin s.s. Witteking of 364ft. in length. A series of excellent photographs illustrates their shipbuilding yard, pontoon docks, and engine works, and a second series is shown of the pontoon dock, containing the s.s. Bayern, under process of being lengthened amidships. At various other parts of the walls of the pavilion are half models representing steamers and sailing vessels, the Hamburg companies owning which are less easily identified than the names of the builders attached to each model. Messrs. Stephens and Sons, of Linthouse, and Charles Connell and Company, of Whiteinch, Glasgow, predominate; but the Germania Shipyard, of Kiel, and Blohm and Voss, of Hamburg, are also in evidence, The Kingsen Line of screw steamers, trading between Hamburg and China and Japan, is represented by several models and photographs; one model being that of the Kriemhild, 324ft. long, and of 3910 tons, built by Messrs. Swan and Hunter, of Wallsend-on-Tyne. A large collection of the older style of sailing vessels frequenting the port of Hamburg, as well as of old two and three-decker men-of-war, and innumerable views and diagrams of things pertaining to the port, and of the various foreign ports to which it is linked by "Giant Steam," are remaining items in a very prolific and interesting display—amounting to a small exhibition in itself. A circular basin containing a map of the world, ocean, and continents, as in the case of the chart shown by the North German Lloyd Company, occupies the centre of the Hamburg pavilion. The map bears upon it lines radiating apparently to all parts of the universe, representing the routes followed by steamers from Hamburg; and actual miniature models identifying the ships of the various lines heighten the public interest in this exhibit. Above the basin and map is a canopy-tower with panel sides, on which are inscribed the names of the individual steamers.

The Red Star Line, conjointly with the International —American—Line, owning the twin s.s. Paris and New York, have a smaller stand almost adjacent to the Hamburg-American Company's. A considerable degree of interest attaches to this stand, as it embraces, amongst other items—models of the s.s. Paris and New York, and of the s.s. Southwark and Kensington for example—a splendidly executed painting of the twin s.s. St. Louis and St. Paul, now building by Messrs. Cramp and Sons, of Philadelphia, for the International Company, and a full size suite of state rooms as fitted up in these new vessels. The first of these ships is to be launched from the yard at Philadelphia sometime this month, and in view of the boast, persistently made by the builders and their friends, to the effect that the new ships are "of American model and design, and built with American materials, skill and muscle"—although many readers will be disposed to take all this, about the "design" especially, a good deal *cum grano salis*—their advent on the Atlantic will be waited upon with interest. The picture at least does not convey the impression that the American built boats differ extensively or in any radical way from the Paris and New York, which have been available as patterns for a considerable time. What the future, or more intimate knowledge of the boats may declare, cannot, of course, be foretold; but that they embody any main features which have not first of all attained their full development on this side the herring-pond, may safely be doubted. The state-room accommodation on board, as exemplified at the Exhibition, is on a scale of even greater lavishness, as regards space and furnishing, than is to be found on the Paris, and this consideration, combined with the slightly higher speed intended—20 knots—may be taken as additional incentives to the patriotism which is likely to find vent in patronage of the rival American "home-built" greyhounds.

The Peninsular and Oriental Company has also an extensive and well-arranged stand adjacent to the Red Star Line exhibits. Prominent amongst the full models shown are those representing four of the company's modern steamers, the Oceana, the Victoria, the Himalaya, and the Caledonia; the last-named being the vessel recently launched, and now being fitted out by Messrs. Caird and Co., of Greenock. As a contrast to this, the latest vessel of its numerous fleet, measuring some 6500 tons and 486ft. long, it shows, alongside, a model on the same scale of the pioneer paddle-steamer of the fleet, the William Fawcett, built in 1829, 206 tons and 60-horse power. A noteworthy and most interesting exhibit is a long glass case containing a seascape, on which have been placed small rigged models, representing in the order of time the whole fleet of the company, past and present, from the small William Fawcett down to the Caledonia recently launched at Greenock. The past and the present order of things are also brought into striking juxtaposition at the P. and O. Company's stand in the matter of marine engines. A large view is given of the engines fitted into the p.s. Iberia in 1837, and, alongside, a similarly executed illustration of the engines fitted into the s.s. Victoria, built in 1887. This gap of half a century's engineering practice is sufficiently suggested to the initiated reader by simply mentioning that the early paddle engines were of the side-lever type, by Messrs. Forrester and Co., of Liverpool, were of 400 indicated horse-power, the boilers being worked at 8 lb. pressure per square inch, giving the vessel a speed of 7 knots per hour, but at the cost of 5 lb. of coal per indicated horse-power per hour. The modern triple engines by Caird and Co. are of 7000 indicated horse-power, the boiler pressure being 150 lb., speed of vessel 17 knots, and the coal consumption 1·6 lb. per indicated horse-power per hour.

The Cunard Steamship Company is represented by a galaxy of highly finished models of its modern steamships, and several of its earlier vessels. The models include the Campania and Lucania, Umbria and Etruria, Gallia, Hibernia, Asia, and the last and first of its paddle-wheel mail steamers, the Scotia, Persia, and the Britannia. It also shows, in the form of a diagram, the gradual increase in the size and power of its vessels from 1840 to 1893, beginning with the Britannia, of 207ft. long and 740-horse power, and ending, meantime, with the Lucania, of 600ft. long and 26,000-indicated horse power.

Here it naturally occurs to us to mention that neither the White Star Company nor its builders, Messrs. Harland and Wolff, are represented in the Exhibition, although the latest and best examples of its fleet, the Teutonic and Majestic, would have conferred completeness on the show as representative of modern transatlantic steamships. While their absence is matter of regret, it is not, on the other hand, matter for surprise that the hopes of some of the exhibition promoters have not been realised regarding a possible "show of hand" as concerns the record-breaker Gigantic persistently rumoured as being under way or contemplated at Belfast.

While Messrs. Harland and Wolff, as builders of the Atlantic liners owned by the White Star Line, are not directly exhibitors, their work in other directions finds representation. The Union Steamship Company, of Southampton, in addition to a magnificent model of its twin s.s. Scot, 6750 tons and 12,000-indicated horse power, built by Messrs. Denny, Dumbarton, shows views and particulars of other vessels of its fleet, including the twin screw steamers Gaul, Goth, and Greek, built last year by Messrs. Harland and Wolff, also a sister ship, the Guelph, 4830 tons, launched from the Belfast yard on the 26th ult. The present month will also see the launch of the company's new mail steamer Norman, of 7500 tons.

The South African Cape mail service is also represented in the section by Sir Donald Currie's Castle Packet Company. At its attractive stand are three full models, representing the Norham Castle, the Dunnottar Castle, and the latest vessel the Tantallon Castle, built by the Fairfield Company, and for some months now in active service on the South African route. This splendid vessel is 440ft. long, by 50ft. 8in. beam, and 35ft. depth, 5636 tons, 7500 indicated horse-power, and steams 17½ knots.

Other important steamship lines represented, and which may here be mentioned, are the Royal Mail Steam Packet Company, which shows a splendid model of the West Indian mail steamer Orinoco, of 4627 tons and 5000 indicated horse-power, built in 1886 by Messrs. Caird and Company, Greenock; the Anchor Line, which shows models of four of its well-known transatlantic steamers; the Allan and State Line, which is represented by photographs of its vessels and a full-size specimen of the second-class berths to be found on board; and the Orient Steam Navigation Company, which exhibits its large mail steamer Ophir, of 6910 tons, and 10,000 indicated horse-power, built by Messrs. Napier and Sons, and the Austral, of 5527 tons and 7000 indicated horse-power, which, as everyone knows, emanated from the stocks at Fairfield.

The display of models made by the Fairfield Company is contiguous to the models of its patrons the Cunard Company, and embraces the Campania and Lucania; the Umbria and Etruria; the Arizona, Alaska, Normannia, and other large Atlantic liners, and well known to voyagers at sea, as their models must now be to exhibition visitors. Alongside that of the Campania, and as if to court contrast, is a model of the sailing vessel Pass of Melfort, a class of production for which the famous Fairfield establishment does not, except in unusually dull times, lay itself out. Other Fairfield models are those of the s.s. Lahn, of the North German Lloyd fleet; and the Dunnottar Castle, of the Castle Packet Company's Cape mail fleet. Of paddle steamers and twin-screws there are the p.s. England, built for the Zeeland Steamship Company, Flushing; the p.s. Queen Victoria and Prince of Wales; the Thames p.s. Kohinoor; the twin s.s. Tynwald, on the service between Liverpool and Isle of Man; the p.s. Rouen and Paris, of the London, Brighton, and South Coast Railway Company's fleet between Newhaven and Dieppe. Two remaining and very diverse exhibits, although the term "yacht" has been applied to both, are the steam yacht Lady Torfrida, of 539 tons and 700 indicated horse-power, built for Sir William Pearce, and the yacht Livadia for the Czar of Russia — the nine days' wonder of her time, but now relegated to the limbo of things all-but forgotten. The only model of Government ships shown is that of H.M. twin screw Magicienne and Marathon, of 3000 tons displacement and 9000 indicated horse-power. On the arched divisions, which define the bounds of the Fairfield Stand, are displayed a varied collection of photographs of engines and machinery, as well as of the Fairfield Company's gigantic works.

Messrs. J. and G. Thomson, of Clydebank, send eight highly-finished full models in glass cases, representing the different class of vessels for which their yard is famous. The collection includes models of the world-renowned p.s. Columbia, of Mr. MacBrayne's fleet; the p.s. Glen Sannox, built two years ago for the Glasgow and South-Western Railway Company; the twin s.s. Fredrica, Lydia, and Stella, built in 1890 for the London and South-Western Railway Company; and the s.s. America, designed and built originally for the transatlantic service between Liverpool and New York, but now owned by foreigners. Besides these, Messrs. Thomson show a selection of their naval ships, including H.M. battleship Ramillies, of 14,300 tons and 13,000 indicated horse-power; H.M. cruisers Terpsichore, Thetis, and Tribune, of 3400 tons and 9000 indicated horse-power; each of the latter having a speed of 20 knots. All these warships are twin-screw steamers, as is the Spanish cruiser Reina Regente, of 5600 tons and 12,000 indicated horse-power, which completes the list of Messrs. Thomson's exhibits.

Messrs. Denny and Bros. of Dumbarton, are represented by a select, though not very numerous, group of models of their productions in the way of merchant steamships and fast mail and passenger paddle steamers, and by a small scale working model of the engines and paddle shaft and wheels of the Dover and Ostend Channel steamers Princess Henriette and Princess Josephine, built a few years ago. A still later vessel, the Leopold II., built by Messrs. Denny for the same service, is shown, while her Belgian-built rival, the Marie Henriette, is to be found represented by a model in the stand of the Société Cockerill adjacent to Messrs. Denny's stand. Naturally, the models and engines of these several fast Channel steamers attract a good deal of attention. Besides the Belgian boats, Messrs. Denny also show models of the successful Clyde river steamer Duchess of Hamilton, belonging to the Caledonian Steam Packet Company, the p.s. London Belle, and p.s. Woolwich Belle, built a year or two ago, and now doing service on the Thames. The collection also includes models of the s.s. Jumna, of 5200 tons, built for the British India Company; the s.s. Antonio Lopez, 3460 tons, built for the Campania Transatlantic of Spain; and the p.s. Shooreah, a many-decked light-draught vessel characteristic of the vessels employed in Indian river service, so many of which have emanated from the yard of Messrs. Denny. Elsewhere in the maritime section, and under the wing of the companies owning the vessels, are splendid full models of others of Messrs Denny's recent productions, including the Union Company's twin s.s. Scot, and the s.s. Southwark, both already referred to.

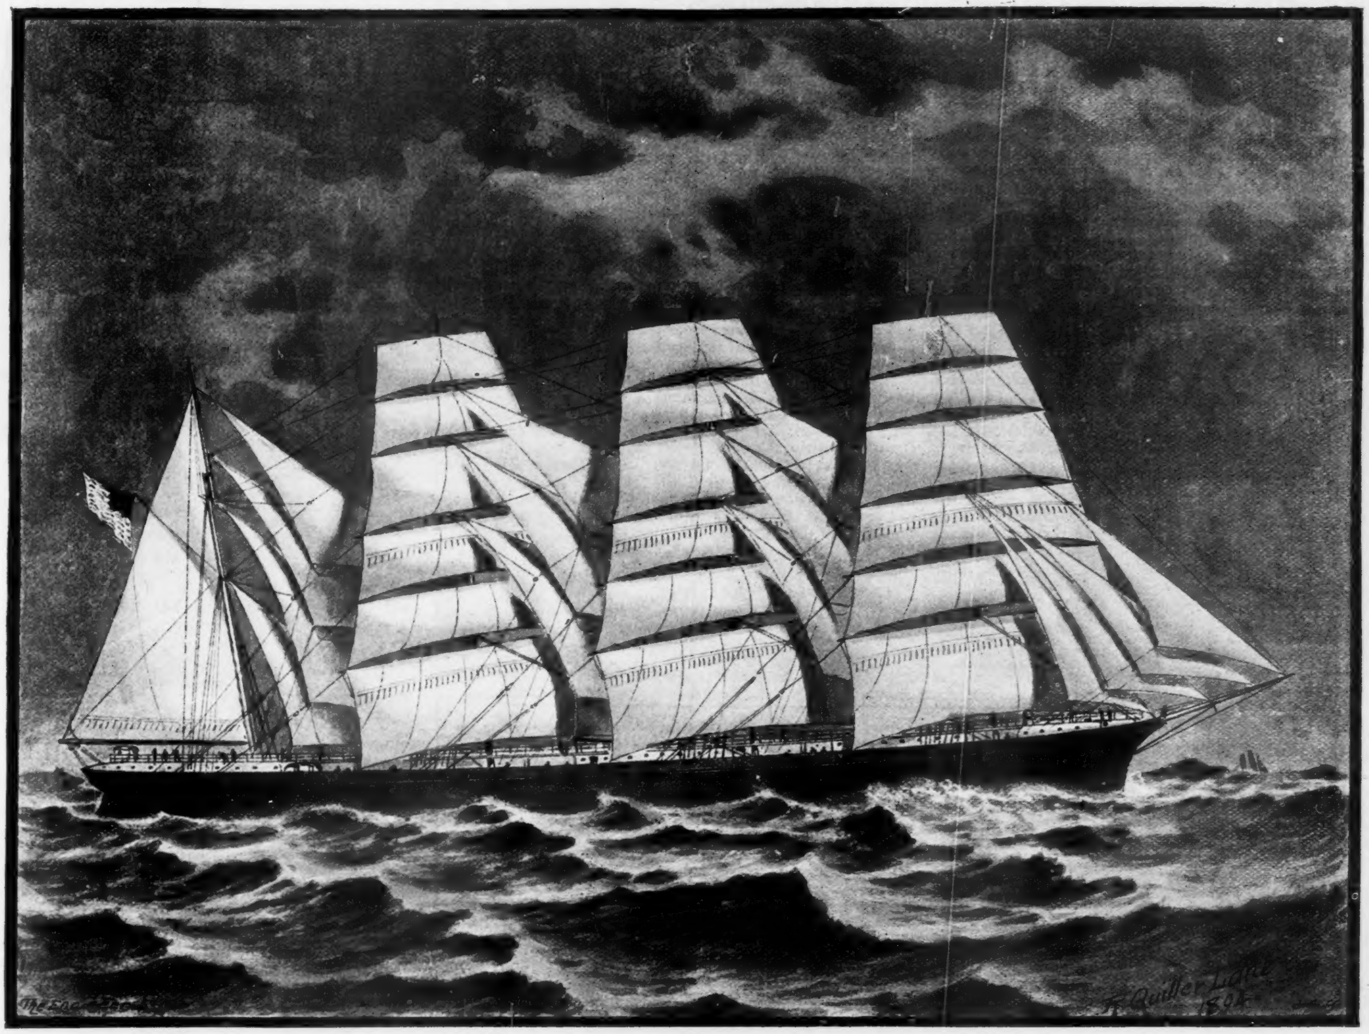
Alongside of Messrs. Denny and Brothers' stand, as already mentioned, is the stand of the Société Cockerill of Seraing and of Hoboken, near Antwerp. The model shown here of the Channel steamer Marie Henriette bears a brass plate announcing in three different languages, amongst other particulars, that she is "the fastest paddle-steamer in existence." Impressed with a due sense of the significance of this statement, it will be easily understood that the public turn with heightened interest to another, and by far the most imposing, exhibit at the Société's stand. This is nothing less than a spare crank-shaft belonging to the vessel herself—a beautiful piece of work seventy tons in weight, and of the hollow-built type. In addition, there are about a dozen other models of the vessels built at the Société's shipyard at Hoboken, where at the present time an additional fast paddle-steamer for the Belgian Government's Ostend and Dover Channel service is being laid down. These other exhibits, however, and that of the splendid full-size working marine engines shown at the Société's stand in the machinery section—which we hope to illustrate—will be referred to in further articles, when dealing more particularly with continental shipbuilding and shipping firms. Notice of the numerous exhibits made by north-east coast of England firms—such as Sir William Armstrong, Mitchell, and Co.; the Palmer Company of Jarrow; Messrs. Hawthorn, Leslie, and Co.; Swan and Hunter; Wigham, Richardson, and Co.; Raylton, Dixon, and Co.; the Darlington Forge Company, &c.—is also deferred.

## NEW WAREHOUSE SHEDS FOR THE MANCHESTER AND SALFORD DOCKS.

With a view of more completely equipping the Manchester and Salford Docks, for dealing with the large cargoes brought by cotton steamers, the directors of the Manchester Ship Canal Company have just given out contracts for the erection of a range of three-storey warehouses. The contract for one portion of these warehouses has been placed in the hands of Mr. Edward Wood of the Ocean Ironworks, Manchester, who has already built for the company a number of one-storey sheds at the docks, and the buildings are being pushed forward with all possible speed, in order to be in a complete state before the arrival of the first cargoes of cotton with the opening of the cotton season, which begins early in October. The warehouses which are now being erected are to be of the latest type throughout, built of fireproof materials, and designed to carry extremely heavy loads on all the floors. They are being built in pairs three storeys high, with a covered roadway between to enable loading and unloading to be carried on in inclement weather. Owing to the unstable nature of the ground the superstructure will rest on a foundation of wood piles, with a bed of concrete on top. Blue brick footings will be built on these, and cast iron base-plates laid on the same to receive the feet of the steel lattice pillars. The main floor girders and floor joists will be constructed of steel. The second and third floors throughout will be composed of concrete 7in. thick with a layer of rock asphalte on top. The first floor will be paved with 4in. stone flags. The roofs over the warehouses will be slated and glazed; and those over the roadway will be glazed throughout to admit ample light for the discharge of the wagons and lurries. The roof principals will in all cases be constructed of steel, and will carry angle-steel laths and purlins for supporting the slates and glass. Iron fireproof staircases will be placed at the ends of the warehouses, to enable access to be gained to all floors. The sides of these buildings will be covered with sliding doors which will run throughout the entire length on all floors. This will enable a steamer to load or discharge at any point along the side, and thus greatly facilitate the transhipment of the goods. On the quayside hydraulic cranes for the handling of the goods will be provided, and on the covered wayside continuous rails for carrying a number of travelling hoists will be supported under the roof. The second portion of the contract has been placed with Messrs. De Bergue and Co., of the Strangeways Ironworks, Manchester, who have in hand the building of two pairs of warehouses, mostly of steel, each pair warehouse being about 300ft. long and 72ft. wide, and there will be a clear space between each of 50ft., covered in with a glass roof. In each of these warehouses the ground floor is raised about 3½ft. above the quay level, and is flagged throughout. There are two upper floors, carried by steel girders and joists, filled in with concrete to make all fireproof, and the warehouses have slated roofs and skylights. A system of iron sliding doors covers in both sides of all the warehouses, giving free access at any point from end to end at every floor. The necessity for increased warehouse accommodation at the Manchester and Salford Docks has long been felt, and the new buildings now being put up will not only form a very important addition to their equipment, but when fully completed will be a distinct advance upon buildings of their class at other seaports.

City Commission of Sewers.—A meeting of the City Commission of Sewers was held at Guildhall on July 3rd, Mr. Alderman Bell presiding. It was decided to repave the carriage-ways of London-wall, Princes-street, and Moorgate-street with Val de Travers asphalte, at a cost of £4450, and the carriage-ways of Bartholomew-close, Beech-street, and Aldersgate-buildings with French asphalte, at an expense of £1375. Other footways were ordered to be repaved with asphalte by the Limmer Company. Reference was made to complaints which had been made in the newspapers of nuisance from sewer ventilators, and the matter was referred to the Streets Committee, the clerk being requested to direct the attention of the London County Council to the matter, as it appeared that one of the deep main sewers under their control was responsible for the nuisance complained of.

# THE UNITED STATES SAILING SHIP DIRIGO.



## THE "DIRIGO."

THIS fine vessel is the first steel vessel built in the United States of America. She was launched last February from the yard of Arthur Sewell and Company, Bath, Maine, and is 330ft. long over all, 310ft. between perpendiculars, 45ft. beam, and 27ft. 3in. depth of hold, designed to carry 4500 tons dead weight on a 22ft. 6in. draught of water, and to stand without ballast when light in port. Her lower deck is composed of stringers and tie plates, planked with 2in. hard pine; main deck of steel. She has raised poop and forecastle with flying bridge extending from one to the other for use in rough weather, and can spread 13,000 yards of canvas.

She is owned by her builders, and started last April on her first voyage to Japan laden with a cargo of 1,210,300 gallons of refined petroleum.

## HARBOURS AND WATERWAYS.

*Belfast.*—The tender of Messrs. Workman and Co. has been accepted for the new branch dock, the amount being £28,945. The works include the extension of the existing branch tidal dock at its southern end for 315ft., so as to form a junction with the northern side of the Prince's Dock; the closing of the river entrance into the Prince's Dock near its eastern side, and filling in the space between this wall and the new river wall to quay level, so as to make a continuous river quay. This scheme, prepared by Mr. G. F. L. Giles, the engineer to the Commissioners, having met with some local objection, principally on the doing away with the entrance to the Prince's Dock, Messrs. Hawkshaw and Hayter, the consulting engineers, were asked to advise on the matter, and having done so, expressed their entire approval of the proposed works, suggesting, however, if the funds would allow of such course, a further extension at a cost of £20,000.

*Hull.*—The trade of Hull is beginning to overset the harm that it received during the strike, and the amount of shipping entering and leaving the port is rapidly increasing. The increase in the foreign arrivals during the present as compared with the corresponding period of the previous year is 200,000 tons, and in the coasting arrivals 64,000; while in the outward trade the increase since the beginning of the year amounts to 305,000 tons. The North-Eastern Railway Company is about to construct, at a cost estimated at £72,000, an addition of 10 acres to the St. Andrew's Dock, with three slipways, and a timber jetty and river wall.

*Barry.*—The directors have invited tenders for the construction of the proposed new 20-acre dock, which is expected to cost between £300,000 and £400,000.

*Ballina.*—The Inspectors of Irish Fisheries have lately been making an investigation into the condition of this harbour. The present accommodation in the river is admitted to be utterly insufficient for the vessels trading to the port. In 1860 Parliament authorised the construction of walls, for the purpose of deepening the channel, and enabling vessels to get up the river. A portion of the works was constructed, but owing to want of funds they were not completed. The Commissioners have recently obtained the promise of a loan of £6000 from the Board of Works for the completion of the work, but as their powers have expired, it became necessary to obtain a provisional order, and hence the inquiry that has recently been held. The fisheries of the Moy are very valuable, and objections to the proposed continuation of the works were raised by the Moy Fishery Company.

*Ouse navigation.*—There have been several attempts within the last few years to get this navigation restored. At the instigation of the County Council the Board of Trade were moved to send an inspector to report on the condition of the locks and other works. A company was also started to purchase the rights of the proprietor; to put the works in order, and extend the navigation by a new cut from Bedford to a junction with the Grand Junction Canal. The proposed Bill for accomplishing this was not proceeded with. Last year the rights of the owner of the navigation passed into the possession of Mr. L. T. Simpson. Soon after the completion of the purchase he commenced restoring the locks and putting the navigation in order. At the end of last year, the St. Ives lock and staunch of fourteen gates, the locks at Hemingford, Houghton, Godmanchester, Brampton, Offord, and St. Neots, with the bridges and tow paths on twelve miles of the river, had been restored. Since then the work has been continued, and includes the entire rebuilding of Tempsford Staunch, Wellington lock, and Castle Staunch. Between St. Neots and Bedford thirty-two new lock gates with sills and hollow quoins will be required, and about twenty-five new flood gates and staunches. It is intended that the traffic shall be worked by the Ouse Transport Company, which has already placed a number of new barges on the navigation, and a steam tug. A fair amount of trade is already being done between St. Neots and Lynn. Although there is no present intention of extending the navigation to the Grand Junction Canal, this work will no doubt be ultimately proceeded with, as it would open up communications between all the Midland district and the port of King's Lynn, and give more direct access for trade to and from the Continent.

*The Provisional Orders* relating to piers and harbours brought forward by the Board of Trade for confirmation in this session of Parliament include the incorporation of the Collieston Harbour Trustees, with power to construct harbour works and to borrow £5000; also of the Polperro Harbour Trustees, with power to borrow £3000 for the construction of new works; also of the Whitelinks Harbour Trustees, with power to borrow £38,000 for new works; an order authorising Mr. Fletcher to construct a pier, quay, and breakwater at Avoch, and to borrow for the purpose £8500; the vesting of the harbour of Burnmouth in trustees, with power to construct a wharf and to borrow £5000; an order empowering Sir T. Campbell Orde to construct a pier at Loch Efort, and to borrow £4000. This order was opposed but confirmed by the committee to which it was referred. An order empowers the Poole Harbour Trustees to construct groynes on the south-east side of the entrance to Poole Harbour, to acquire the sandbanks, and to borrow £5000.

*Rouen.*—The statistics of the navigation returns at this port are interesting, as its position and circumstances are frequently referred to as corresponding to those of Manchester since the canal has been made; in fact, it has been termed the Manchester of France. From the consul's report for last year there appears to be a marked decline in the amount of shipping, following on an unbroken increase for the previous twenty years. The number of vessels increased from 3750 in 1872 to 5986 in 1891. This increase was due to the improvement of the channel of the Seine by training and dredging between Rouen and the estuary. In 1892 the number of the vessels declined to 5229, and the tonnage from 2,435,850 to 1,932,029. The import of coal, wine, and wheat has considerably decreased. The import of wood, lead, bar iron, and petroleum had increased, but not in sufficient quantity to make up for the decrease in imports. Although Rouen has better facilities for railway distribution than Havre, the imports of raw cotton to the former port do not show any marked tendency for the transfer of the cotton market to Rouen. The total import of cotton last year was 628 tons, being an increase on 1892, but a falling-off from 1431 tons imported in 1891. The largest ships which navigated the 70 miles of the Seine to Rouen varied from 1100 to 3750 tons, and included grain ships from New Orleans, Melbourne, Odessa, petroleum ships from New York and Batoum. The greatest draught of any vessel on entry was 22ft. Nine-tenths of the imports consist of coal, timber, petroleum, and grain. The trade in timber to Rouen is falling more to British vessels, contracts which have been refused by Swedish ships, on account of the low freights offered being taken by British vessels. This is the more remarkable as it is well known that a British ship cannot be run at so low a cost as that of a Norwegian or Swedish. It is partly explained by the fact that vessels which would not be allowed to trade in this country, owing to the ever-increasing requirements of the Board of Trade, are being parted with at low prices for purely continental traffic. As regards the trade in coal, timber, and raw materials, Consul O'Neil says: "A very great part is played in the transport of these essentials to a manufacturing country by such a canal system as that of France. It is impossible for an Englishman to see, without regret, the abandonment of a systematic canal construction in his own country. With foreign manufacturers on every side competing, and too often successfully, with British, it seems to one who observes this from abroad that we must be seriously handicapped by so great a want. Every element in production is being pared down to the lowest possible limits, and wages, if we may judge from recent events, are to be no longer squeezable. Prices, we are now told, must start from the bed rock of a living wage. Is the constant perfection of water transport in foreign manufacturing countries a matter of so little concern to us? More especially in the production of coal, timber, and raw materials, in whose cost manual labour or wages form so large an element." Canals in France transported, in 1892, 25,957,686 tons of merchandise, and railways, in 1891, 96,553,763 tons, the proportion being 26 8 per cent. Although the trade to Rouen shows signs of depression, improvements in the port and navigable waterways are being carried on in a very extensive way. The quays and appliances for rapidly loading and unloading vessels are being greatly extended; gas is being replaced by the electric light, so that work may go on during the night; additional railway connections and facilities are being provided; the petroleum basin is being doubled in length and area, and the shoal places in the river are being dredged away. An increased depth of from 3ft. to 4ft. has been secured through the

Bourdonville Pass at a cost of £54,308, and it is intended to spend a further sum of £25,000. It has also been determined to dredge the Banc de Flaques for a width of about 500ft. to an increased depth of 3¼ft., at a cost of £40,000. This shoal consists of hard conglomerate, and forms a bar across the river which materially hinders the free flow of the tidal water. The greatest improvement, however, which has been carried out is the lighting of the estuary channel with gas-boat buoys. Within the last five years the system of marking the estuary channel has been twice changed. First, iron buoys were substituted for poles crowned with faggots, which had served for many years before. After three years' use these were changed to boats carrying a lantern lighted with compressed gas. The result has been so satisfactory that the testimony of pilots and mariners is that it is now as easy to navigate the twelve miles of the estuary by night as by day, and that the system is as good as any that could be desired, and renders the navigation perfectly safe, except in foggy weather.

*Suez Canal.*—The annual report of the directors shows that there has been a marked decrease both in the number of ships and in the tonnage which passed through the canal during the past year. The total number of steamers, 3341, is the smallest since 1887, and is 218 less than in the previous year. The gross tonnage is 1½ millions less than in 1891. The average gross tonnage has increased during the last ten years from 2437 tons to 3219 tons, being an increase of 32½ per cent. The maximum draught allowed for vessels passing through the canal four years ago was 24ft. 7in.; now it is a foot more; 164 vessels drawing more than 24ft. 7in. used the canal. The percentage of vessels drawing under 23ft. has declined from 73 to 69 per cent.; the vessels drawing more have increased from 26·69 per cent. to 31·07 per cent. England still maintains her position, although the proportion to other nations shows a decrease from 77·63 in 1891 of the whole of the tonnage passing through the canal to 74·18 in 1893. Germany stands second with 7·43 per cent.; France 6·53 per cent., an increase in the past three years of 1·48 per cent. Holland has increased from 3 to 4·12 per cent. Of the total number of vessels passing through 92¼ per cent. used the electric light, which is an increase of about 1¼ per cent. on the previous year. The average time taken by vessels which only navigated in daylight was 31 hours 24 minutes, and of those which continue their passage during the night by the aid of the electric light 19 hours 52 minutes. The improvement works have been regularly proceeded with.

## THE MAGNIFICENT AND MAJESTIC.

The two fine battleships which are building respectively at Chatham and Portsmouth, the Magnificent and Majestic, are progressing with rapid strides. The disposition of their armour is of so different a character to that employed, even in the most recent battleships, that we have engraved a sketch elevation and plan, indicating the immense development which has been effected. Although we have, however, adverted in the drawing to the side armour as "vertical," it is not in reality vertical, but slopes backwards to a considerable degree, as the French plan of making the ship's sides "tumble home" has been adopted to a modified extent by the constructive department of our Admiralty.

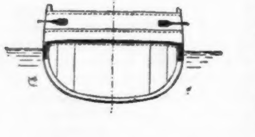
Aft Barbette
Plan Shewing Armour Deck
Forward Barbette

In order to show how the armoured surface has increased since the days when the "Admirals" were designed, we also append a drawing of the Collingwood, whose comparatively meagre and insufficient defence is apparent at a glance. It will be observed that the old plan of starting the armoured side streak a few feet below the surface of the water has been adhered to, the thickest portion of the steel plates reaching to the level of the flat lower deck, which rests upon the crown of the arch of the armoured lower deck. Thinner steel armour is carried up to the level of the main deck. But the most important modifications are in the armoured deck and barbettes. The armoured deck, instead of being a mere flat roof to the citadel, curves downwards on each broadside to the armour shelf, or lower edge of the side armour; so that, in addition to having the side armour to penetrate, a projectile would meet with 4in. of steel set at an angle which would give a further reinforcement of about 6in. to pass through. The height of the curve of the armoured deck is about 9ft., and it extends unbroken from apex to apex of the citadel. It will thus be seen that the outer edge of the armoured deck stretches from stem to stern in a horizontal line. This is a most invaluable feature of the new designs, and was never attempted before, the horizontal line of the armoured deck being raised above the citadel in all earlier battleships. The barbettes rise at either end of the citadel, and are pear-shaped, passing upwards through main and upper decks, beyond the latter of which they project a little, and upon their summits will be revolving armoured hoods or turrets, as in the cases of the Barfleur and Renown. The bulkheads of armour which enclose the ends of the citadel are in reality merely a prolongation of the side armour, which is carried round thus to meet the barbettes at the central line, and they enclose the curved slope of the armoured deck, being built against it.



Another important feature of improvement which is observable in these ships is the greatly extended inner skin. It reaches unbroken to two bulkheads some 8ft. or 9ft. forward and aft of the apices of the citadel, and is thus very much more effective than in any ships previously designed. The unprotected ends of these two new battleships really sink into insignificance. The extent of armoured surface from apex to apex of the citadel is nearly 300ft., and it is almost inconceivable that any injury to the unprotected portion would be of so serious a character as to affect the trim or stability of these vessels to a dangerous degree.

## GAINSBOROUGH WATER SUPPLY.

At the latter end of last year the Gainsborough Local Board of Health obtained the sanction of the Local Government Board to a loan of £12,500 for the purpose of carrying out a scheme of water supply in accordance with the designs and estimates of their engineer, Mr. Jabez Church, M. Inst. C.E. The Board have, however, since considered the risks attached to this scheme—see The Engineer, vol. lxxvi., page 337—which involved the construction of a heading 25ft. long from the bottom of a well 250ft. deep to their existing boring—which is only 10in. diameter in the sandstone—and finding also, on a careful test of this boring, that its capacity was hardly equal to their requirements without tapping it at a greater depth than 250ft; they have now decided to abandon the original scheme and to substitute a new and independent boring for the well and heading originally contemplated. This alteration of plans, while involving a slight additional cost, will secure a perfectly new and independent supply of water; it will also avoid the risks and difficulties connected with making the heading to the boring at a considerable depth from the surface, and it is anticipated that the extra size and depth of the new boring will not only increase the amount of water available, but will enable it to rise to a higher level when being drawn upon by the pumps, thus reducing the lift.

The scheme now proposed, which has been designed by Mr. Church and approved by the Waterworks Committee of the Local Board, consists of a single boring 1450ft. deep—or 700ft. into the water-bearing sandstone—18in. minimum diameter at the bottom, 30in. diameter for a depth of 300ft. from the surface, having a 20in. lift pump suspended in it, worked from a direct-acting compound condensing engine, also a force pump worked from the tail rod of the low-pressure cylinder. Unfortunately it will be impossible, owing to the great depth of the water-bearing strata below the surface, to have two borings side by side with a pump in each, as would be the most satisfactory and economical plan; consequently the pump rods will be balanced by means of adjustable counterweights carried on the rocking lever. The total capacity of the new plant will be—as in the original scheme—from 50,000 to 60,000 gallons per hour under a maximum total lift of 400ft. Application is now being made to the Local Government Board for their sanction to the alteration to the scheme.

## OLD ROMAN PUMPS.

The illustrations here given will be interesting to some of our readers who are not in the habit of visiting the British Museum, or for whom, at all events, those rooms which contain the Roman antiquities possess no attraction. At the same time it may serve to take some of the conceit out of engineers of the present day to see how much the Romans knew 2000 years ago. The origin of the pump is attributed by Vitruvius to Ctesibius, of Alexandria, about 224 B.C., although we know that Danaus, brother of the Pharoah Rameses, as far back as 1485 B.C., used pumps when digging the wells at Argos. In either case, however, the origin is Egyptian. In his work entitled "Spiritalia seu Pneumatica," 130 B.C., Hero described pumps precisely similar to these, and seeing how complicated they were, it is reareasonable to infer that the invention must have been in his time quite old. We are therefore inclined to think that the theory attributing the design to Ctesibius is the preferable.

We illustrate two pumps, of which that shown in Fig. 1 is probably the older, having flap valves, that shown in Fig. 2 having lift valves of an astonishingly modern design. The flap valve shown by Fig. 1 *a* was usually a coin—Lat. *assarius*, an older form of "*as*." From this the word "*assarium*" was derived, which Vitruvius always employs, and the Greek word ἀσσάριον which actually means a "valve." The castings appear to be of a rich gun-metal, and have as neat a surface as is produced in modern foundry practice.

Fig. 1—A

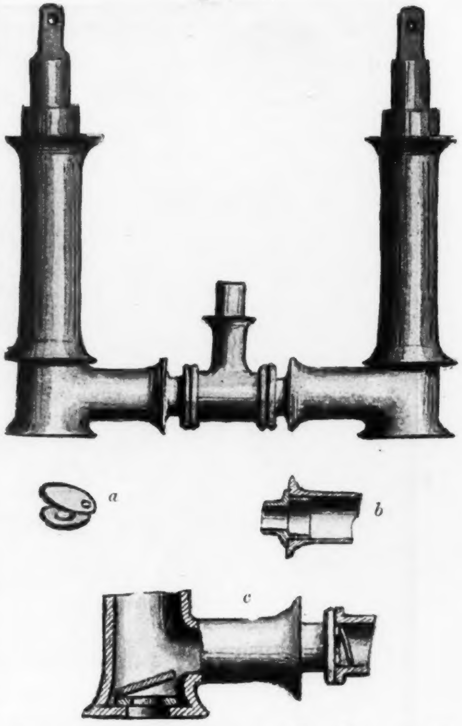


Fig. 2—B

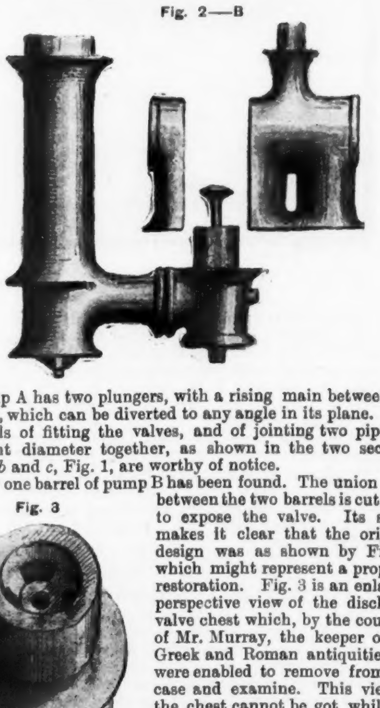

Pump A has two plungers, with a rising main between the barrels, which can be diverted to any angle in its plane. The methods of fitting the valves, and of jointing two pipes of different diameter together, as shown in the two sections given, *b* and *c*, Fig. 1, are worthy of notice.

Only one barrel of pump B has been found. The union piece between the two barrels is cut open to expose the valve. Its shape makes it clear that the original design was as shown by Fig. 4, which might represent a proposed restoration. Fig. 3 is an enlarged perspective view of the discharge valve chest which, by the courtesy of Mr. Murray, the keeper of the Greek and Roman antiquities, we were enabled to remove from the case and examine. This view of the chest cannot be got while the latter lies in the case. The valve spindle is guided by the ferrule, which can be seen supported by our webs, with which it does not appear to be of one casting, but driven in, while the water is enabled to rise through the annular orifice surrounding the ferrule. In the barrel of this are the remains of a connecting-rod, still hanging on to the piston, which is immovable. It is consoling to know, however, that the Romans knew nothing of the *lift* pump. Atmospheric pressure was not estimated then. That was left to the Spaniards to conceive, and the Italian Torricelli to determine.

Fig. 3

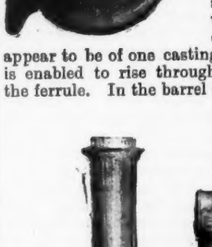

Fig. 4

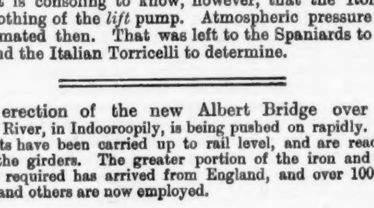
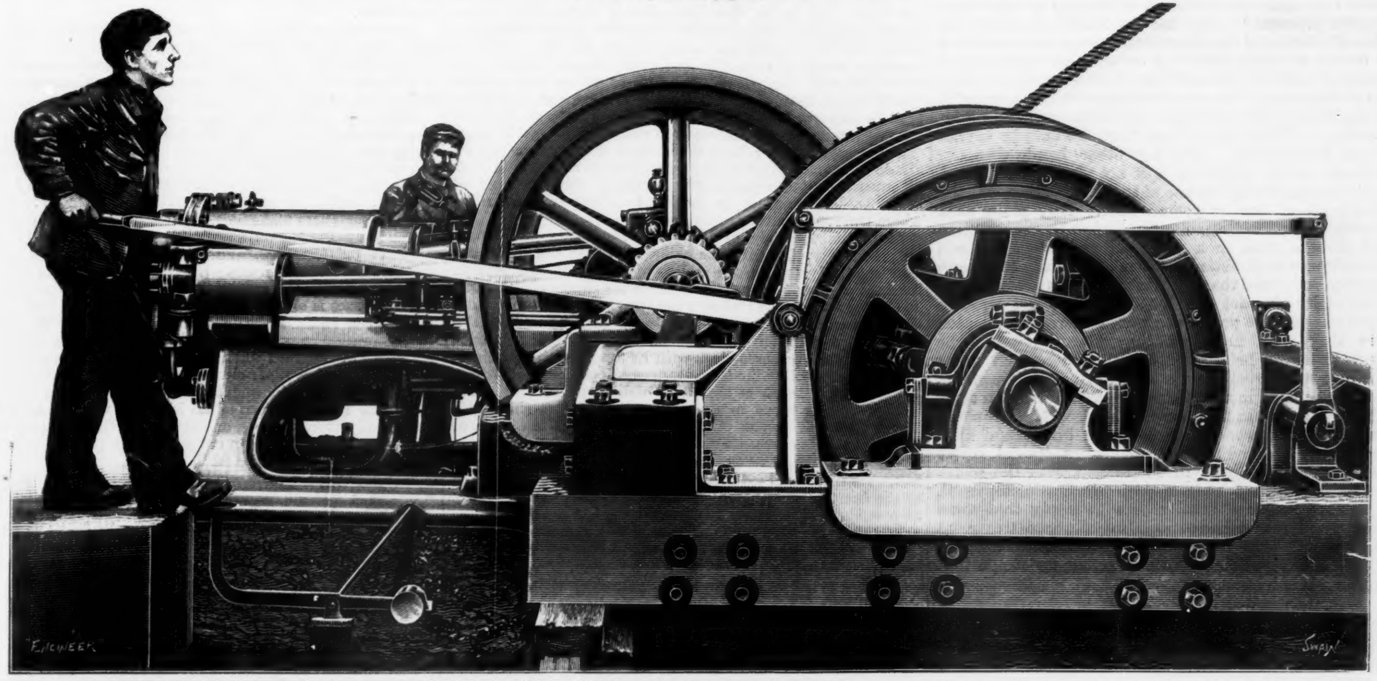


The erection of the new Albert Bridge over the Brisbane River, in Indooroopily, is being pushed on rapidly. The abutments have been carried up to rail level, and are ready to receive the girders. The greater portion of the iron and steel material required has arrived from England, and over 100 iron workers and others are now employed.

## TWENTY-HORSE POWER OIL ENGINE AND WINDING GEAR

MESSRS. PRIESTMAN BROS., HULL, ENGINEERS

(*For description see page* 9)



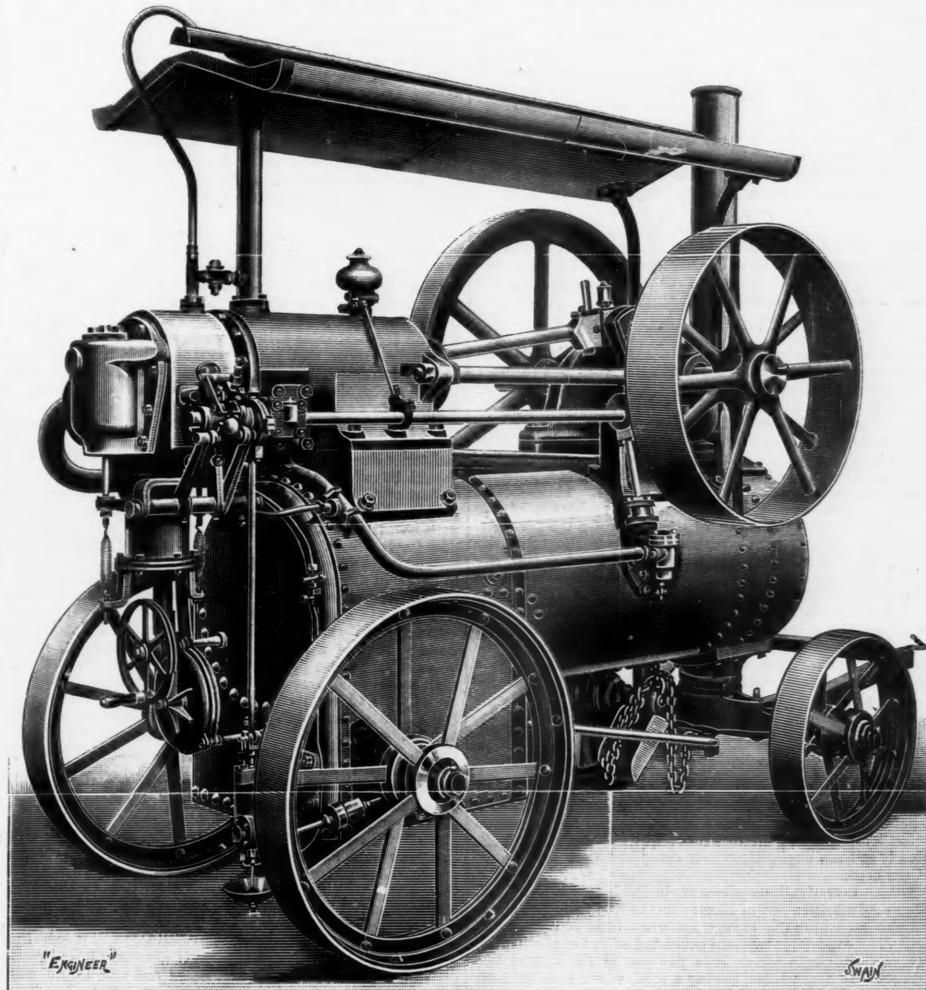
## NEW RUSSIAN STEEL SHOT.

A PLATE trial is reported in the *Times* to have taken place at Ochta, near St. Petersburg, on June 28th, which is specially to be noticed on account of results obtained by the mysterious shot of whose powers we have heard occasionally, though nothing definite has been declared. The trial on June 28th was decisive as far as a single experiment can be pronounced to be so. Three armour-plates were tested, two measuring 8ft. by 8ft. by 6in., made by Messrs. Cammell and Brown, and one by the latter, 8ft. by 8ft. by 10in. All of them had been treated on the Harvey and Tresidder system. They were attacked by a 6in. Oboukhoff gun, 45 calibres long, firing two kinds of projectiles—namely, first, the best projectiles which could be made on Holtzer's system at the Putilof Works, which projectiles past experience has shown to be practically identical with Holtzer shot purchased direct; and secondly, similar projectiles to which the secret Russian improvement had been applied. The rounds were fired at the 6in. plates with about 1850 foot seconds striking velocity, while at the 10in. plate the striking velocity was 2400 foot-seconds. It is stated that one projectile of each kind was fired at each plate, that the plates were curved, and that the angle of incidence was from 8 to 10 degrees with the normal. The Holtzer projectiles proper broke up, but obtained greater penetration than has yet been reached under comparable conditions in England, while the "secret process" shells passed right through the targets and cut holes in a wooden screen in rear which, as we understand the account, were so clean as to argue that the projectiles were uninjured. No one, however, was allowed to see them after recovery—the secret being jealously guarded. Of the excellent performance of these projectiles then there can be no doubt. That these had energy enough to pass clean through the plates goes without saying. No projectile can be expected to perforate with less than the theoretical energy; the excellence of the treated plates has shown itself in defeating projectiles whose energy would be sufficient to perforate by breaking them up, as, indeed, on this occasion took place with the Holtzer shells proper. By Krupp's formulæ the calculated direct perforation due to the striking velocity against the 6in. plate was 13·8in. of iron, or 10·3in. of steel, and against the 10in. plate, 17·1in. of iron, or 13·7in. of steel. The obliquity would reduce this slightly, and moreover would render the projectiles much more likely to break. Consequently, seeing that the plates were supplied by Brown and Cammell, and that striking superiority is shown by direct comparison with projectiles of very high quality, and is maintained without exception in each case, we must admit, as we have said above, that the extraordinary power of the Russian projectiles has been as completely proved as it can be in a single trial.

We now pass on to the question as to what these "secret process" shot are. Interesting as such a question is, we fear we are not in a position to throw very much light on the subject. We can, however, inform our readers what we have heard from time to time on the matter. From one to two years ago, the Russians considered that they had projectiles which were not liable to be broken up by treated plates. The device they adopted was the use of a wrought iron cap, as mentioned in THE ENGINEER of June 16th, 1893, in an article headed, "Armour Question Puzzles." It must be understood that the function of the hard skin of a treated plate is to break the extreme point or tip of the projectile before it enters and obtains support from the surrounding metal. The importance of this has been curiously illustrated more than once. For example, in the Texel trials last autumn it was found that at low velocities projectiles absolutely entered more deeply into all the treated plates than into the one untreated plate, the probable explanation being that this St. Chamond untreated plate was as a mass harder, and so when the shot point held, it carried itself with the thin hard plate skin round it more deeply into the softer treated plates than with the stiffer mass of the untreated one. When the velocity rose, however, the projectiles were broken by certain treated plates while they perforated the untreated plate without failure. This is a single experiment, but taking it for what it may be worth, the above is the best explanation that can be suggested so far as we know. The action of the wrought iron cap is then quite conceivable; it saves the point from an abrupt shock and supports it, and thus, under favourable conditions, may save the projectile from fracture at the critical moment, and enable it to do its work. This device was tried at Shoeburyness in 1878 and rejected as untrustworthy and worse than useless at oblique impact. Its functions might be more complete when applied to overcome a thin film or skin such as is given to plates by the water hardening than when the earlier and inferior shot were opposed by steel whose hardness, though less, extended some inches in depth. Nevertheless the Russians burst one gun by the cap coming off in the bore and acting as a wedge; and considering the difficulty of angular impact, it was expected that the idea would be dropped. Shortly after this it became known that the Russians had obtained remarkable results

## 10-H.P. PORTABLE OIL ENGINE

MESSRS. ROBEY AND CO., LINCOLN, ENGINEERS



against treated plates with certain very small projectiles, but all attempts to obtain information were unsuccessful. The matter was declared to be "a Russian secret." No doubt the projectiles fired last week were of the same nature as the small ones previously tried; the question is, were they some modification of the cap or something altogether different? That the cap could be made to hold we do not doubt, and the chances may seem to be against a new device suddenly following on the first without any connection with it. Nevertheless there is strong evidence of some departure. It cannot be supposed that a wrought iron cap of the form used by us would be carried through the armour. We know, in fact, that it would be spread out and left behind. On the other hand, that the excellence of the projectile was not due to treatment alone, is suggested by the use of the wood screen and the concealment of the recovered shot. Any plain steel projectile that passed clean and unbroken through a plate would show no trace on a wood screen, except perhaps some obliquity in direction, and might hardly tell more tales when recovered than it did before it was fired, beyond the fact of its abstract excellence. We do not know at present whether the projectiles were allowed to be seen before they were fired. If they were allowed to be actually handled before firing, the presumption is no doubt that their excellence is due to special treatment, invisible of course in the unfired shot, but of which signs might be detected in the recovered projectile. If, on the other hand, they were concealed both before and after firing, we are inclined to think that some special device may have been employed in connection with the point. The fact that finished Holtzer projectiles were employed, and all the language used, seems to imply that some distinct device rather than a special metallurgical treatment way employed. The test at an angle further suggests that the device was such as specially called for such a test. More than this we cannot say.

## THE RESISTANCE OFFERED BY CURVES ON RAILROADS.

AN elaborate series of experiments have recently been made in France to determine the resistance due to curves on railroads. The results are discussed at great length in a paper in one of the bulletins of the International Commission of the Railroad Congress. In the following lines we give some of the principal results obtained, and must refer those of our readers who may wish to follow the matter up more closely to the original paper. The point which it was sought to determine by these experiments may be summed up in the words, "What means would experience appear to dictate as the most efficacious for reducing the resistance to the passage of rolling stock over curves?" In some experiments made on the Eastern Railroad of France, it was found that with passenger trains of from eight to twenty carriages running at a speed of from 22 to 30 miles per hour over curves of from 2625ft. radius and upwards, the influence of the curve is not appreciable. At 35 miles per hour there is a sensible increase in the resistance amounting to about 5 per cent. With freight trains running over curves of 3281ft. radius, 2·2 lb. per ton must be added to the unit of resistance, and on curves of 2625ft. 3·3 lb. per ton. The length of the curve appears to be the greatest factor in influencing the increase of resistance. The above-cited coefficient applies to trains whose average running speed is considerably below that for which the elevation of the outer rail has been calculated.

The results of experiments made at various times on the Paris-Orleans line suggests the following formula :—

$$C = 1000 \frac{V}{R^2} n,$$

where C = additional resistance in kilogrammes per ton, R the radius curvature in metres, V the speed in kilometres per hour, on the number of ordinary four-wheel carriages in the train. This formula becomes :—

$$C^1 = 4200 \frac{V^1}{R_1^2 n},$$

where $C^1$ = English pounds per ton, assuming French and English tons to be the same for the purposes of a formula in which the constant must of necessity be only approximate: $V^1$ = miles per hour; $R_1$ = yards; $n$ = as before.

The values yielded by this formula should be added to the normal resistance of the train under consideration. Thus for a train of thirty trucks, running over a curve of 1148ft. radius at a speed of about 12½ miles per hour, the increase of resistance would be about 10·5 lb. per ton. This amount is just a trifle over the actual rolling resistance of the train, and is practically equal to the effect of a 0·5 per cent. up gradient. More recent experiments seem to show that the values yielded by this formula for curves of short radius, say less than 650ft., are too high. Mr. Fetter, engineer-in-charge of the rolling stock of the departmental roads of France, has deduced the following results by assuming that the diminution of speed of a train when running from the straight on to a curve—all conditions being maintained the same on the curve as when on the straight—could be relied on as a measure of the increase of resistance offered by the curve:—

| | |
|---|---|
| Load hauled .. .. .. .. | 19 to 81 tons. |
| Gauge of rails .. .. .. | 3·28ft. |
| Gradient .. .. .. .. .. | 0·24 per cent. |
| Radius of curve .. .. .. | 984ft. |
| Nature of rolling stock .. | Locomotive, combined duplex, Mallet type. |
| Remarks .. .. .. .. .. | Resistance not appreciable. |

Mr. Fetter, therefore, was led to the conclusion that on a road of one metre gauge, with carriages having two axles and a wheel base of 8·2ft., the resistance due to a curve of 1000ft. radius is at least negligible when compared to a gradient of 0·24 per cent.

Further investigations were made in 1891 by the State Railway Administration of Saxony on the line from Chemnitz to Annaberg, where the curves are sometimes of a radius of 560ft. The experimental train consisted of five cars with two axles each, having a wheel base per car of 19¾ft., and two carriages with three axles, having a total wheel base of 23ft. The whole seven cars were fitted with apparatus whereby the axles could be made to act radially or as rigid axles. The influence of a sharp curve—560ft. radius—was found to be exceedingly marked. The initial resistance was doubled when the axles were allowed to work radially, and was increased by 270 per cent. with the axles rigid. For curves of 980ft. radius the increase was about half as great.

The paper also deals with the question of the super-elevation of the outer rail. This, as is well known, is generally regarded as facilitating the passage of a train over a curve, and doubtless, if a train were running perfectly smoothly, and the plane of the rails happened to coincide with the normal to the resultant of the centrifugal force at each point, and the weight of the train taken to act vertically through the centre of gravity of the portion considered, this might be the case. But in practice, the authors observe, the super-elevation has for a long time been regulated by the maximum speeds at which trains are to run; hence for low speeds the carriages must of necessity be forcibly drawn against the inner rail, and the resistance increased, either because the inside flange touches the rail or the conical part of the tire acts in the wrong direction, so that the largest circle of contact between the wheel and the rail is on the inside rail.

There seems to be little doubt that the experiments we allude to have established one point clearly, and that is that all super-elevation could be with advantage banished from all goods yards, sidings, or, in general, from all parts of the line where the speed is necessarily low.

As to the widening of the gauge at curves, this would only appear to increase the obliquity which the axles can take relatively to the centre line of the road, and thus to increase the angle of contact between the flange and the rail. It has been found that when a car travels over a curve under the influence of an original impulse, it takes up in general a well-defined position relatively to the line. The outside wheel of the front axle bears with its flange against the rail, the axle tends to incline from its normal position relatively to the carriage as much as the play which is given it will allow. This incline is taken in such a way as to give the inside wheel as much lead as possible, the axle tends to deviate as much as possible from its radial position.

The inside wheel of the back axle just touches the inside rail. Its flange and axle tend to incline in the same direction as the front axle, still giving the inside wheel as great a lead as possible, and inversely to what takes place to the forward axle, this inclination tends to bring it to a radial position.

The bulletin then goes on to discuss the theory of how resistance is set up at some length. The measuring instrument used is novel, and will be of interest to those studying the subject. It is composed of a pendulum, the inclination of which to a vertical scale measures the positive or negative acceleration of the carriage; the pendulum in its motion traces a line upon a length of paper, which is unrolled by a clock train. The variation of the ordinates of this line from the vertical is proportional to the resistance opposed to the car. Their variation, when the car enters on a curve, indicates the increase of resistance due to the curve, and this applies equally well whether the car is hauled by a locomotive or is moving under some initial impulse, or to an engine alone moving under a motive effort, which is kept as constant as possible. The mechanism has the further advantage of being portable.

As to the action of the wheel base upon the resistance offered by a curve, it is found that the pressure of the front wheel can be lessened by introducing a third axle. Now, as regards the distance these should be apart, it is evident that as the distance between two rigid axles is increased, the arm of the lever is increased, also in most cases the obliquity of the front wheel is increased, and there is additional tendency to cause resistance. The variation of the wheel base, however, does not appear to cause any very marked influence on the resistance until a very long wheel base is reached. On the other hand, if the wheel base is decreased too much, the obliquity of the leading wheels, after passing a minimum, begins again to increase, and this in proportion as the play on the rails increases. The very short wheel bases, therefore, are not so efficient in minimising resistance as might at first sight be anticipated. Cars with bogie trucks behave exactly like two separate cars with short wheel bases, and they do not show such a marked increase in resistance on a curve as might be expected, compared with other cars with longer and rigid wheel bases.

The following are the conclusions arrived at by the Commission:—(1) It is possible, under favourable conditions, to construct lines with a gauge of 4ft. 8½in., and with curves varying from 500ft., and even lower under exceptional circumstances, and that it is possible to work these roads with the rolling stock used in France. This applies specially to six and eight-wheeled coupled goods engines. Also that most of the passenger and goods wagons would pass over such a line in safety. This opinion is supported not only by the tests just dealt with, but by information regarding the practices in France and abroad. (2) In projecting new roads the following data may be accepted:—Increase of resistance due to curves of 650ft. radius = 8·8 lb. per ton; increase of resistance due to curves of 492ft. radius = 13·25 lb. Gradients should be reduced in proportion. (3) A geometrical examination of the problem as applied to passenger and goods wagons shows that, with the usual arrangement of axles and with new tires, a two-axle wagon, with rigid wheel bases, will pass freely over a curve of 330ft. radius as long as its wheel base does not exceed 46ft. (4) The widening of the gauge tends to admit of a greater obliquity of the leading axle, and is therefore of little or no use. (5) The stability against overturning is calculated as a function of the gauge, radius of curve, height of centre of gravity and speed. Under the worst possible conditions, namely, that of a passenger car with seats on the roof, a speed of 46·6 miles per hour would have to be reached before such a car would overturn. During the experiments separate carriages, and even entire trains, were impelled on to the experimental line at 37½ miles per hour without exhibiting any tendency to overturn, or even showing any marked oscillation. (6) From the point of view of shock and the tendency to derailment, all observations made at speeds varying in some cases from thirty-seven to forty-one miles per hour, have shown that the passage over curves of 330ft. radius, or even from one curve to the reverse curve, can be accomplished with considerable smoothness. (7) As long as the line was kept in good condition and improved by repairs, wherever indications of such improvement were noticeable the average resistance of the curved portion of the experimental line fell to as low as 17·64 lb. per ton. (8) Greater or less side play did not appear to have any appreciable influence upon the resistance measured. This influence, if it exist at all, would seem to be unfavourable, as it allowed of side motion. (9) The super-elevation of the outer rail was found not to exert any influence on the resistance. (10) Freedom of adjustment of axles seems to slightly decrease the resistance, but in several consecutive experiments dissimilar results were obtained, so that this must not be taken as a conclusive result. (11) The long bogie carriages do not differ in specific resistance from two axle-cars. Different experiments gave a coefficient of from 17·64 lb. to 18·74 lb. per ton. A slight defect in parallelism of axles decreases the resistance in one direction and increases it in the other. (12) Newly turned tires, with a decidedly pronounced conicity, give less resistance than those whose flanges have been worn to almost a vertical face. (13) A goods engine with four axles should, without allowing any lateral play whatever, pass over a curve of 262½ft. radius. Hence a curve of 330ft. radius would leave a certain amount of play, even in the case of rigid wheel base.

The average resistances obtained were:—Passenger engines, four wheel coupled, 19·8 lb. per ton; goods engines, six wheel coupled, 17·6 lb. per ton; goods engines, eight wheel coupled, 17·6 lb. per ton. It is stated that lightening the load on the leading axle materially decreased the resistance.

*Results of experiments with trains of variable length.*—Experiments were made with trains of ten, sixteen, and thirty cars. The latter was about 820ft. long, and extended almost the entire length of the curve with three bends along its length. The following observations were made on a curve of 246ft. radius, at a speed of 25 miles per hour:—(1) All engines, passenger and goods wagons, used in every-day work on the large French railways will run perfectly freely over a curve of 328ft. radius, and even at 246ft. radius on the standard gauge of 4ft. 9in. (2) Increase of gauge offers no advantages. (3) The interposition of a straight line between reverse curves is of use only from the point of view of play at the buffers, and may be limited from 33ft. to 65ft. (4) All super-elevation may be dispensed with without compromising the safety of the train when passing over curves even at high speed. Excessive super-elevation may act very prejudicially in causing the displacement of the axles towards the inner rails. (5) The resistance of all kinds of wagons, as well as engines of different types, on curves of 330ft. radius averages about 17·6 lb. per ton. On curves of 246ft. radius the average resistance does not exceed 22 lb. per ton.

The experiments as a whole show that a variation of the wheel-base and of the speed—within the moderate limits obtainable—do not influence the resistance to any very marked extent, and that lightening the load in the leading axle decreased the resistance offered by the curve. The results obtained by oiling the flanges are interesting. It was found that a diminution of increase of resistance was observed varying from 17 per cent.—of the increase observed with unoiled flanges—on a curve of 660ft. radius, to 25 per cent. on a curve of 492ft. radius, and to 27 per cent. on a curve of 330ft. radius. On the Brighton Railway a jet of exhaust steam is turned on the leading flanges for the same purpose.

## EMIGRATION PROSPECTS.

THE July circulars of the Emigrants' Information Office, 31, Broadway, Westminster, S.W., show the present prospects of emigration. The best season for going to Canada is far advanced, and emigrants who intend to go there this year should not delay; the principal demand is for experienced farm labourers, there being no real demand for mechanics, except in a few cases.

In New South Wales the number of unemployed about Sydney is said to be decreasing, many men being employed in road-making and in prospecting on the gold-fields. A large number were assisted to the fields by the Government Labour Bureau, and nearly all of them have done well. Several thousand persons have gone to the new gold-fields at Wyalong—some 300 miles south of Sydney—but a warning has been issued against more miners going there, as "the field is overdone." The coal-mining industry has been in a very unsettled condition, and several hundred men in the southern collieries struck against a reduction of wages, but it is hoped that a settlement has now been arrived at. At the large Newcastle Collieries to the north of Sydney, the output of coal is increasing, and the selling price of coal and the wages paid to miners have been proportionately reduced. Under the new shearing agreement, which applies to other colonies also, the employers propose that the shearing rates in Southern Riverina should be reduced to 18s. per 100 sheep shorn, but that elsewhere the rates should be the same as those of 1893, *i.e.*, 20s. per 100. The shearers are refusing to accept these terms. Taking New South Wales as a whole, there does not seem to be any opening for more emigrants at the present time, other than domestic servants.

The monthly official reports from Victoria, dated 20th March and 30th April last, state:—"The pressure upon the labour market has been much relieved in consequence of the efforts of the Government to place men upon the land, and to give employment to others upon works of a reproductive character. The railway lines, which have been in course of construction in the Mallee district, in the north-west, being nearly completed, the Government have determined to extend them still further without waiting for the sanction of Parliament. The men to be employed will be selected from among those whose names are registered at the Railway Department for employment, and care will be taken that only those who have been some time in the Colony, and are deserving of employment, will be given work." Several of the principal brickyards, which have been closed during the last eighteen months owing to the great depression in the building trades, have been re-opened and are employing a number of men, while a large order has been given for pipes for the new drainage works of Melbourne. During the first quarter of this year the output of gold in Victoria was 2475 oz. more than in the first quarter of 1893, and fresh discoveries both in the gold mining and coal mining industry are being reported.

In South Australia there is no demand for more hands.

In Queensland there is no material improvement in the building trade at Brisbane; but the erection of the new bridge over the Brisbane River is giving employment to ironworkers, navvies, pile drivers, masons, and labourers, of whom, however, there are plenty on the spot. In the north there is no demand for emigrants without capital; but as land is now very cheap, a man with a capital of £600 would find a good opening.

In Western Australia there has been a large influx of miners from other parts of Australia to the new Coolgardie gold fields, but water has been scarce, and no one is advised to go there from this country without some money and experience.

In Tasmania there are considerable numbers of men, both in the chief cities and in the country districts, who have been for some time past, and who will be for some time in the future, largely dependent upon relief works provided by Government.

New Zealand continues to be prosperous, but there seems to be for the most part a sufficiency of labour, this being now the winter season.

In Cape Colony the Labour Commission, which has been sitting for more than a year, has just issued its report. It recommends the formation of a Labour Bureau, and states that there appears to be no strong desire or demand for the introduction of European labour, except for that of female servants. The new education report of Cape Colony calls attention to the dearth of experienced teachers in the Government schools.

Considerable changes are about to be introduced in connection with granting passages to Natal; at present free passages are being given to female domestic servants, and artisans can obtain assisted passages on the application of colonists resident in the colony; there are new Crown Land Regulations which are intended to facilitate the settlement of the lands in the colony.

With respect to Mashonaland and Matabeleland no one should go there at present, unless he has a capital of £200 to £300, and is competent to take up mining, prospecting, trading, building, or some other work; the railway from Beira is now finished for seventy-five miles.

## OIL ENGINES AT THE R.A.S.E. SHOW.

Returning to the engines which were the subjects of the trials to which we have referred in previous impressions, we may, with the object of dealing with them more fully, again take them in the order in which they stood in the trial shed.

In The Engineer, vol. lxxiii., page 539, we divided the various forms of oil engines exhibited at the Warwick Show into a series of types or classes. The classification has been very generally followed since, and the number of types has not been since increased. In 1892 six makers exhibited seven engines, while only two years before there were only two engines entered for the prizes offered for small engines at Plymouth, namely, the Priestman and the Knight engines; the latter having been unsatisfactorily made, and working improperly. Since that time, however, the system has been properly carried out by another firm of makers, and with excellent results. The classification referred to is as follows.

1. Engines in which the charge of oil is prepared for admission to the cylinder by a spray maker which forms an oil shower readily converted into a vapour on its entrance into the heater and cylinder.
2. Engines which receive and convert the oil into a gaseous vapour in an extension of the working cylinder open to the cylinder.
3. Engines which receive and convert the oil into a gaseous vapour in an oil-receiving jacket extension of the working cylinder, but not open to the cylinder except by a valve controlling admission of the vapour thereto.
4. Engines which receive and convert the oil into a gaseous vapour in a vaporiser separately heated by an oil lamp with forced air combustion.
5. Engines in which ignition of the charge is effected by an electric spark.
6. Engines in which ignition is effected by an ignition tube heated by an oil lamp with forced air combustion.
7. Engines in which ignition is effected by the heat received by the charge from the hot walls of the combustion chamber aided by that due to compression, and its effects.

The first engine is that of the Britannia Company, which comes under classes 4 and 6. Its general appearance is shown by the engraving herewith, and the system of working and construction of the vaporiser may be described with reference to the annexed sectional sketch, which also serves to show the arrangements adopted for directing heated currents of air past and through the drop-by-drop supply of oil. This is admitted by a plunger valve controlled by the governor, an arrangement which causes the air to evaporate and take up the oil as vapour on its way into the cylinder. Another feature, which was formerly used in this engine and is claimed to be an important one in gas engines, is a small chamber or pocket connected with the cylinder in which some of the air required for the working charge is imprisoned and compressed to, say, 40 lb. on the square inch, the piston then covering the port to this chamber and compressing the remainder of the charge to the advantageous pressure of about 80 lb. per square inch. In the oil engine, however, this pocket is now discontinued because unused oil vapour would sometimes explode early in it and push the piston hard against the opposite side of the cylinder. This sketch, Fig. 2, shows the general form of the apparatus, and is similar to that used in the engine illustrated in The Engineer, vol. lxxv., page 257. The air enters at A into the casing B containing the annular channels C. The casing B also forms the cover for the ignition tube, and is heated by the same flames. The air traverses all the channels C, passing from one to the next, and becomes highly heated by contact with the metal wall. It then passes to the tube D, which conveys it to the air space E in the oil feeder F; J is the oil cock. The small plunger G is reciprocated by a lever 2, shown on the end elevation of the engine, and the groove H is pushed forward into the oil space I, and, being filled with oil, is returned just at the commencement of the suction stroke of the engine to the position as shown in the air space E, when the heated air, moving at a high velocity, sweeps off, mixes with, and evaporates the oil. The mixture then proceeds by the pipe K to the annular space or chamber L at the top of the ignition tube casing, and thence by the pipe M to the admission valve of the engine N. Additional heated, or slightly heated air is admitted by the cock O through the pipe P, which is connected to a channel cast in the cylinder cover. The oil, by these means, is thus vaporised by the heated air, and at the same time intimately mixed by the high velocity air current, the two being finally heated, and perhaps gasified, together, on their way to the cylinder, where complete gasification is effected under the influence of the high temperature of the cylinder and of compression of the charge. The further air supply which is admitted by the main air valve when the engine has got well under weigh is slightly heated, when working under ordinary conditions, by its passage through a coiled air pipe in the exhaust box.

The governing of the engine is effected by graduated oil charge, the hit-and-miss finger missing or catching one or other of three steps on the piece which actuates the small oil feeder rod G. On this rod there are several grooves instead of the one shown. The reduction of the speed of the engine is thus accompanied by the introduction of a larger supply than when speed is normal. This system does not, however, always operate satisfactorily; for instance, when a miss is made and the engine is on a dead load, two revolutions with a moderate weight of fly-wheel gives sufficient time for a large reduction of speed, so that after a miss, comes a large quantity of oil, some of which is not completely used on the first working stroke, and is liable to be fired on the next compression stroke. This upsets the working for two or three strokes and causes irregularity. At the trials, for instance, this engine would make from twenty to thirty strokes with regularity in speed and with perfectly satisfactory combustion. Then would come the one miss, followed by a quarrel between vaporiser, governor, heat in cylinder, imperfect combustion of the large introduction of oil, and exhaust of useful oil vapour. When the introduction of the extra quantity of oil is followed by complete evaporation and a sufficient quantity of air is present for combustion, a heavy explosion occurs, speed is accelerated, miss again occurs, oil is cut out, and the speed may or may not fall just sufficiently to let in the small quantity of oil. When it does the engine gets off again and runs regularly for a considerable period. If, however, the speed falls quickly after a heavy explosion, as it may if the fly-wheel is light, then the large oil

supply occurs with repetition of the results already mentioned.

When this engine is to be started the exhaust valve is held open by a finger-piece which is placed upon a collar upon the cam shaft. This prevents the exhaust valve lever from falling to the position for a closed valve. Thus no compression can take place. But to put the lever again into action automatically, a screw thread is cut in the collar referred to, and the finger follows this as the shaft is revolved. The finger arrives at the end of the thread after two revolutions, and reaches a simple groove normal to the axis, which, of course, gives no motion to the finger. In its passage from one end of the screw to the other the finger has moved the exhaust lever from the position on the cam, where it is concentric, and by which the valve is held open continuously, to the part of gradually increasing excentricity. In starting the engine the quantity of air drawn into the cylinder and the amount of compression is thus gradually increased automatically. The engine, as will be seen, is fitted with an air pump, which serves to supply the vaporiser lamp, and to force air into the oil vessel to supply it to the valve; the latter was not used in the trials.

During the long duration trials of this engine the combustion was perfect, except for the occasional big explosion and accompanying effects as described, but it is obvious that this may be remedied. We would prefer to run the engine with probably a single groove in the little feed rod G, Fig. 2, and to govern by complete cut-out and by the exhaust valve. The engine is of small dimensions for its power, as shown by the long runs and the full power trial, and it contains features of great importance.

The next engine is the 4-horse power nominal of the Campbell Gas Engine Company. This again is of the classes 4 and 6, and although it differs in detail, the essential features are the vaporisation of a certain quantity of oil by introducing it into a vaporiser with a current of inrushing air. The vaporiser has been modified since we published a perspective view of it on the 8th December last. Its construction is roughly shown by the accompanying sketch, Fig. 3, and the action of it and of the engine is as follows:—When the speed of the engine is such that it causes the governor to operate for the admission of oil, and of vapour, and air, the exhaust valve is allowed to close. On its first outstroke the piston then acts as a pump and takes in air and anything else that can go in with it. The cylinder is in communication with the vaporiser by a pipe at E. The inrushing air which enters at A, pulls the valve V down against the resistance of the spring S, which may be varied by means of the nut N. In passing the valve V the air carries oil from two small oil holes C communicating with an annular oil supply passage B. The fine jets of oil under, $\frac{1}{16}$in. in diameter, are dashed into spray as they leave the valve, and hit the surfaces D. The rush of air and the eddies thus thoroughly prepare the oil for complete vaporisation in the hot vaporiser. It will be noticed that an essential point is observed, namely, the inlet of a quantity of air with the oil into the vaporiser, the best and probably the only means of preventing harmful deposits. Below the vaporiser is a heating lamp, the flame from which impinges upon the igniting tube, T, and at the same time heats the vaporiser, the lost products of combustion passing out at the holes in the surrounding jacket shown. The quantity of oil admitted is not determined by the size of the holes C, but by a feed-cock on the oil supply pipe. The oil jet holes C might, in fact, be larger than they are, and by the use of a closely-adjustable cock the quantity of oil might be adjusted apart from the self-adjustment which automatically follows from the adjustment of the air valve. Thus, although the oil no doubt does get sprayed as it is admitted at high speed against the surfaces D, the apparatus cannot be included in the spray maker class. With the exception of the use of a small oil pump and this vaporiser, the engine is the same as the Campbell gas engine, and it works well. On two or three occasions bad starts were made with the engine, because attempts were made to run the engine before the vaporiser was ready. Otherwise the engine ran well, and when working on either full or on half load, with the exception of very few intervals, the combustion was perfectly satisfactory. When running light the combustion was not so good, but this was more notably the case with the previously-described engine. This is not, perhaps, of the greatest importance, as people do not buy engines to run idle. The Campbell Company's engine has the merit of simplicity, and although like several others it is susceptible of improvements, it is already a practical commercial engine.

The next engine is that of Messrs. Clark, Chapman, and Co. It is made under Butler's patents, and comes partly under classes 1 and 3, and under Class 5. It has moreover another peculiarity, namely, that it is started by means of a small quantity of a highly-volatile oil, such as benzoline, and it is afterwards worked by the heavier oils like Russoline. The fixed engine is illustrated by the accompanying engraving, from a photograph, of the valve-side of the engine. The valve rotates once every two revolutions of the engine, and acts both as mixed vapour and air inlet, and exhaust outlet. It is slightly taper, and is kept in its place by a spring at the smaller end, the spring being adjusted as to compression by the set screw seen in the engraving. Fig. 4 is a diagram transverse section of the valve and of the vapour and air mixer. The exhaust leaves the back-end of the valve, and passes beneath a conical surface on its way to the space F by means of an inlet, broken away to show the outlet B. Air for the main supply enters at the end of a jacket J surrounding this space F, and ultimately finds its way as indicated by the arrows past the ejector or inspirator apparatus, containing the central double-coned plug P. The exhaust in the space F thus heats the air as it enters, and again after it is in the mixing ejector and in the space E on its way to the valve V. The oil used for working is first passed over the exhaust heated cone just mentioned, and then as a vapour finds its way through a pipe O V and enters the injector just behind the plug P, and is thoroughly mixed with the air, partly on entrance and partly in the eddy space E. The governing is effected by the throttle valve T, moved by the governor and lever $T^1$. The throttling automatically varies the quantity and strength of the charge, as the plug P moves with the inrushing air against the resistance of the spring S more or less, according to the quantity of air passing T. From this description it will be seen that the mode of working of the Butler engine is the same as was described with reference to the small engine illustrated in THE ENGINEER, vol. lxx., pages 65-66, the chief difference being that in the engines of 1894 the oil is first admitted through a separate very finely-adjusted annular nozzle, so that it sprays over the exhaust heated cone referred to, and without any admixture of air, as far as we know, passes to the apparatus shown in Fig. 4, where it mixes with the main air supply.

battery, but in the portable engine, and presumably in the fixed, when the engine is at work on full load, the ignition takes place automatically by the internal and compression heat, and the battery is then cut out. The governor, by means of which the air throttle valve is actuated, is of the fly-wheel type. The engine runs smoothly at a high speed, and although its use of a battery and of a pint or two of benzoline for starting is against it for farm use, it need not be so much so for town use. The consumption by this engine was only obtained during the long duration trials, which we did not witness, and are not given in the table on page 10, but judging from its subsequent running, the alleged consumption, and the imperfect combustion, it is probable that it and some others of the engines would, under ordinary working conditions, work better than they were worked at Cambridge.

The next engine is that of Messrs. Crossley Brothers. This engine was illustrated in THE ENGINEER on the 30th June, 1893, page 575, and has since then been but slightly modified. It belongs to classes 4 and 6, the ignition tube being heated by a forced combination oil lamp fed by an air pump, and the flame from the same lamp is enclosed in a chimney which contains a coil or coil-like passage, into which oil is supplied by a hit-and-miss valve. Air is also admitted to this annular or coil passage, entering by passages in the top part of the annular chimney over the ignition tube flame. The important features of heated air admission to the oil to be evaporated and of vaporisation, independent of the fluctuations of the exhaust temperature, are thus secured. It seems to be thoroughly understood now that for clean and effective vaporisation and gasification, air, and preferably hot air, must be admitted with the oil to the hot retort or other vaporising surfaces. Messrs. Crossley use an ignition timing valve, and the engine is similar, but smaller, to that of the portable engine of which we gave an exterior view on page 540 of our issue of the 22nd ult. During one of their runs, the full power trial of two hours, the hit-and-miss actuated valve-rod was fouled by a temporary device for working a miss counter, and this made a stop necessary, but in other respects this engine worked well and the combustion was perfect. The consumption by this engine is given in the table, page 10.

The next engine in the shed is that of Messrs. Fielding and Platt. It belongs to classes 4 and 6, the vaporiser being of the form roughly indicated by the diagram,

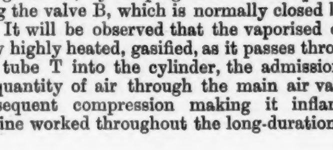

Fig. 3—FIELDING'S VAPORISER

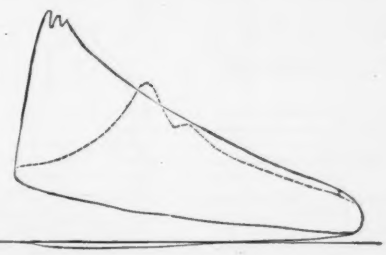
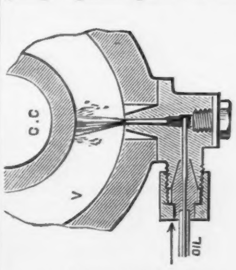
Fig. 3, in which T is an ignition tube heated by a lamp below, the same lamp flames heating the tube V above it, which acts as a vaporiser and is separated from the ignition tube during working strokes by the outwardly closing valve B. The apparatus is surrounded by a hood, as shown by the engravings on page 567 of our last issue. Governing is effected with a hit-and-miss and a rotating governor, by keeping the exhaust open and by actuating the valve B, which is normally closed by a coil spring. It will be observed that the vaporised oil from V is very highly heated, gasified, as it passes through the ignition tube T into the cylinder, the admission of the further quantity of air through the main air valve, and the subsequent compression making it inflammable. This engine worked throughout the long-duration trials; but the combustion was seldom satisfactory, and Mr. Fielding found that he could not get sufficient air to his lamp to maintain the required high temperature of the vaporiser and ignition tube. The effect of this may be seen in the diagrams of which the annexed sketch affords an illustration. The normal diagram of the engine and vaporiser is shown from memory in the full line



diagram, Fig. 5. The dotted line shows the sort of diagram that was being obtained, but generally the expansion line was higher than that of the proper diagram. The very late and slow ignition and burring being due to the cause mentioned. The engine ran the full-load two-hours' trial, but not the half-load and light runs. The alterations necessary to secure the required high temperature will probably be easily made.

Our notice of the remainder of the fixed engines entered for trial must remain until next week.

Messrs. Robey and Co.'s fixed horizontal engine, illustrated by the annexed engraving, is made under Bell and Richardson and Richardson and Norris's patents. It comes under classes 2 and 7, but it differs in principle from many of the others in the Show. The oil is injected under considerable pressure by a pump against part of the surface of the vaporiser, which is an extension of the back of the cylinder. It is of annular form, *i.e.*, one chamber, namely, the combustion chamber C C, inside another, with an intervening space V, but with a few holes in the wall of the inner chamber, so that it is connected for passage of the vapour with the annular space. The vapour is formed partly by the injection of the oil across the space V against the inner wall of the vaporiser, and partly by subsequent heating, at first by an exterior heating lamp, and afterwards by the internal heat due to combustion. At the rear end of the cylinder is a casting containing the main air admission valve. This and the arrangements for heating the vaporiser for starting are also seen in the illustration of the portable engine by the same firm—page 5. The pump which forces the oil into the jet piece, as indicated by the above sketch, is kept constantly at work, and the governor acts by causing all or none of the oil to be returned to the overflow tank. The hole through which the oil is sent in as a jet is a very fine one, and the constructors rely upon a combination of jet spray and surface vaporisation, the air passages being so made that a portion of the air passes over part of the heated surfaces and carrying the vapour with it. The vaporiser has been made in several forms, but the system of working remains the same as formerly, and is sufficiently indicated by the above sectional sketch. Messrs. Robey and Co.'s engines were not entered for the trials.



ROBEY VAPORISER

Messrs. J. and F. Howard entered an engine for trial, but were unable to get it ready in time for the Show We have not seen their engine yet, and the patents concerning it being in the early stages we are not much informed concerning it, but gather that it is of the vaporiser type without either jet, atomiser, or spray-maker.

The portable engine entered by the Clarke's Crank and Forge Company is of the vertical type, as shown by the engraving, page 7. The vertical form is said to be used to secure uniform wear of the piston, and a continuous lubrication of all internal parts. This is not, however, unattended by disadvantages. The engine is said to develope 9 brake horse-power, and has been made with alterations under Root's patents. Ignition is by tube, enclosed in and heated by the lamp which heats the vaporiser. Circulation is obtained in the water jacket by means of a pump worked from a rocking shaft at the back of engine, to which is also attached the oil feed gear and air pumps. The undercarriage is surmounted by a closed cab, the woodwork of which has been constructed in panels, so as to be easily removable at the will of the attendant. The centre panels are removed in the first of our illustrations. The engine was started, but the vertical form was soon seen to be very much against it for portable purposes, especially when worked on a piece of soft watery ground. We do not illustrate the engine in detail because we think that the makers will probably discard the vertical form of engine for the purpose as not suitable, especially with a single-cylinder four cycle engine. The trolley upon which it was placed is, moreover, obviously a first essay in this direction, and the arrangement which necessitates running fly-wheels in slots is dangerous as well as inconvenient for driving.

Messrs. Priestman exhibited a number of their well-known engines, but they made no entry for the trials. The engraving on page 5 is from a photograph of a 20-horse power engine, similar to one of four different engines they exhibited. The engraving shows the engine as it has been supplied for colliery purposes, with winding gear. Messrs. Priestman have, we understand, for some time past been turning their attention to oil engines of larger power. The engine illustrated has two cylinders, and therefore gets one impulse at every revolution of the crank. It is fitted with the self-starter, and with an electric igniter, which can be run, we are informed, from 500 to 800 hours without recharging, or any attention being given to the cells. We are not acquainted with the nature of the improvement by which this is effected, but it must be accepted as an important one for oil or gas engines using electric ignition, which will no doubt be more extensively used than hitherto for engines in towns. The arrangement of the engine and gear it drives is clearly shown by the engraving, and needs no description.

*To be continued.*

---

## A NEW MECHANICAL FLUID.*

By Charles Wallace Hunt, New York City.

A hydraulic piston for adjusting journal boxes to take up the wear from use would have the desirable features of delicacy of adjustment and ample rigidity for any strain which it would be called upon to sustain. The cost of the accurate construction needed and the probable leakage of the fluid would usually prevent serious consideration of this method.

In canvassing the various methods of adjustment which could be used in the bearings of the connecting-rods of our steam engines, the advantages and faults of this method were carefully investigated. The inevitable leakage of the liquid presented an almost insurmountable barrier to its use. The thorough examination of its availability for this purpose, however, brought to mind the method of packing the plungers of mine pumps used by Mr. Eckley B. Coxe, which has since been presented to this society in a discussion of topical questions at the New York meeting, December, 1893.† This method was to fill the spaces for the packing material around the plunger with untried tallow, cut in pieces about an inch across, and kept under sufficient pressure to make it flow into the packing spaces. The tallow packing also lubricated the piston, and as it was gradually worn away, the membranes in the tallow were too large to pass between the plunger and its casing, and remained, forming under the pressure a mass of semi-fluid packing. If we consider this material as a fluid, we can conceive of it as a liquid with masses of animal membranes for atoms, instead of the usual conception of atoms of infinitesimal size.

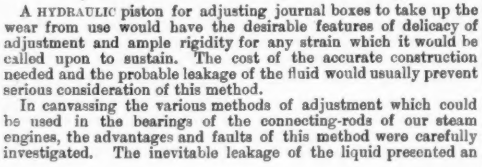

FIG. 1

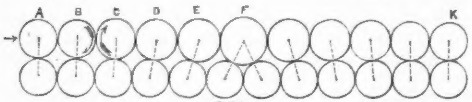

FIG. 2

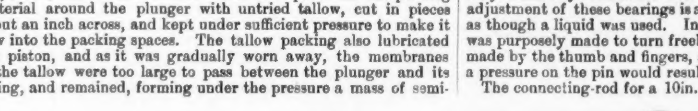

FIG 3.

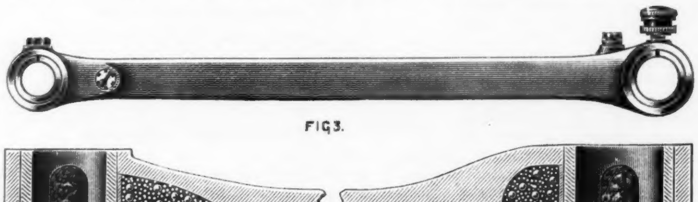

FIG 4.

After making this wide departure from our ordinary conceptions in molecular physics, we can take a further step by imagining a liquid which was composed of atoms as large as bicycle bearing-balls. The anticipated trouble from the leakage of the fluid would then disappear as a factor in the ordinary mechanical fitting in steam-engine work.

If the balls of this hypothetical fluid vary in size, their mutual pressures may be supposed to balance each other somewhat as shown in Fig. 1. The lower balls are of equal size, and the upper ones of varying diameter. The ball A is placed directly over the centre of the lower ball, and has no tendency to move in either direction, but the balls B, C, D, E, and F are each larger than the preceding ball, and each one rests upon the inclined surface of a supporting ball, all together throwing a horizontal pressure on the ball F. A similar series of balls is shown on the opposite of the ball F, and the whole system of balls from A to K is in equilibrium, with no tendency to move. The whole system, however, is in a position of unstable equilibrium, and will move if the lightest pressure is applied to the ball A in the direction of the arrow. If the balls were infinite in number, and the size limited, but with an infinite number of variations of diameter within the limits, the various local pressures would be balanced, and the mass would have the mobile property of a liquid.

The actual movement of the upper system of balls would result in a movement of revolution in each of the balls. Assuming that the friction of the lower ball would cause each one of the upper balls to revolve, the surfaces in contact in the upper system would move in opposite directions, as shown by the arrows in the balls B and C. This friction would depend upon the material, the smoothness of the surfaces, and the lubrication of the balls, and can be likened to that property of a liquid which is known as viscosity.

Under compression each ball of a mass of various sizes would have the resultant of all the pressures on it at its centre, and consequently would be in a position of equilibrium; but should the enclosing envelope change in form of capacity, a change in the direction of the pressures would take place; first, in the balls nearest to the movement, then in the adjoining ones, the balls severally moving in the direction of least resistance, until the resultant of the pressures again came in the centre of each ball.

If the mass of balls were all of one size, they would interlock in a manner analogous to the illustration in Fig. 2, where a series of balls is shown, with a set of the same size resting upon them, interlocked in the spaces of the lower set. If a pressure in the direction of the arrow is applied, it must raise each ball, and the pressure required would be in proportion to the distance or to the number of balls moved. This rigidity resembles the property of a solid.

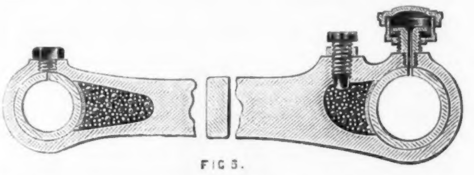

FIG 5.

If these balls of equal size had different coefficient of expansion by heat, it could be imagined that at some higher temperature these balls would become of different sizes, when they would cease to interlock, the mass becoming a fluid above that temperature, a property analogous to the melting point of a solid.

If the balls had different coefficients of compressibility, a great pressure on the mass might change the relative diameter of the balls enough to change the solid mass to a fluid.

A mass of balls of various sizes, under pressure, does act like a liquid, as we have ascertained by testing in various ways. On the table, at the reading of the paper, is to be found a connecting-rod of full size fitted up to be adjusted in this manner, just as it is used in practice, and also a model with a glass front and a spring piston, which permits the individual motion of the steel balls to be seen when the adjusting screw is turned. The mass is kept mobile by putting sufficient pressure on the movable piston.

Fig. 3 is an elevation, and Fig. 4 is a cross section of a solid-end connecting-rod, having an annular brass bushing with an opening, in order that adjustment for wear can be made. One side of the bushing is held in place and adjusted by the pressure of a mass of hardened steel balls, varying in diameter from ⅛in. to ¼in. Between the bushing and the balls is a thin plate of hardened steel, to prevent the balls from indenting the softer metal. The adjustment for wear is made by forcing the mass of balls forward with a hardened steel adjusting screw—Fig. 5.

When the wear has become so great that the range of the adjusting screw has been exhausted, a few more balls are inserted under the point of the screw, and an adjustment of the bearing made as before. On the crank end of the rod, the adjusting screw is on top, but on the crosshead end it is on the front side, clear of the crosshead, where the adjustment is as conveniently made as it is on the crank end.

We have been running last year forty bearings of this type in various places, in the East and in the West, working with steam boiler pressures of from 80 lb. to 160 lb., giving pressures per square inch of projected area of the pins ranging from 600 lb. to 1000 lb. The pressure on the balls per square inch is about 50 per cent. greater. If we assume that the balls are about ⅛in. in diameter, and that sixty balls are in contact with the bushing on each square inch, the pressure sustained by each ball would be from 15 lb. to 25 lb. Assuming that the elastic limit of the steel in the connecting-rod shown is 30,500 lb. per square inch, and that the hardened steel balls have a pressure of 25 lb. on each one, we would expect that each ball would embed itself in the steel envelope until the area sustaining the pressure was strained to the elastic limit. This area would be $\frac{1}{1275}$ of a square inch for each ball, which is almost exactly equal to the area of a circle $\frac{1}{100}$in. in diameter. At first the bearings require frequent adjustment, but the balls soon get in a fixed position, and then they need adjustment for the wear of the bushing only. The adjustment of these bearings is apparently as delicate and positive as though a liquid was used. In cases where the adjusting screw was purposely made to turn freely, the adjustment could easily be made by the thumb and fingers, and if care was not used too great a pressure on the pin would result.

The connecting-rod for a 10in. diameter cylinder steam engine here shown is a steel casting made by I. G. Johnson and Company, fitted with an adjusting screw having fourteen threads to an inch, and a pressure area of balls on the bushing eighteen times the area of the screw. If the screw is turned with a force of 25 lb. on an 8in. wrench, the friction of the screw absorbing 25 per cent. of the force, the pressure on the bushing would be over 50 tons. While this pressure might be used in other applications of this novel fluid that have been proposed, it was clearly out of place in connecting-rod bearings, and we now make the head of the adjusting screw of such a form that an ordinary wrench cannot be used, and the adjustment made only by a spanner which will, by its peculiarity, remind the engineer that care is necessary in the adjustment.

---

While surveying for the Chittagong-Akyab-Minhla Railway, in Burmah, large quantities of coal have been discovered in the vicinity of the operations.

---

* Presented at the Montreal meeting, June, 1894, of the American Society of Mechanical Engineers.

† "Transactions American Society of Mechanical Engineers," vol. xv., page 599.

## RAILWAY MATTERS.

The work of the new Electric Railway between the City and Waterloo Station has already been commenced by the contractors, Messrs. John Mowlem and Co., who seem to be losing no time.

The United States Government has issued an order that all the rolling stock of the railway companies in Uruguay is to be fitted with the vacuum brake in such a way as will allow of the interchange of the stock over the whole system of railways in that State.

A serious accident on the B. and N.-W. Railway, India, was attributed to the rails having expanded from the intense heat of the weather. The engine of a goods train was thrown off the line, the fuel caught fire, and the guard's van was burnt. The line was blocked for several hours.

The Kolar Goldfields Railway was handed over to the Madras Railway Company on the 1st instant. It starts at Bowringpett and runs through the mining camps of Balaghat, Oorgaum, the Champion Reefs and the Mysore Company, being ten miles long. It is expected that the line will greatly facilitate the working of the Mysore goldfields. Four trains run to and fro daily.

The survey of the Nong Khai Railway is progressing favourably, and it will probably be completed this month. Throughout the length of the line easy gradients prevail, and, on the whole, the undertaking promises to prove very cheap. One drawback to be contended with is the scarcity, during the dry season, of water for the locomotives. This difficulty, however, is to be overcome either by sinking wells or by leading water by conduits from the adjacent mountains.

The directors of the Midland Railway purpose erecting, in Sheffield, works for the manufacture of oil gas. The oil is distilled from shale found in Scotland, and the gas made from it is capable of compression—which ordinary coal gas is not. The advantage is, that a large quantity of oil gas can be stored for use in the train. The company have found electricity too costly. They have started an oil gas factory at Derby, and intend constructing others in large centres such as Sheffield and Nottingham.

The proposed extension of the Salonica-Monastir Railway to the Adriatic has been abandoned, the Italian engineers who surveyed the country to be traversed by the proposed line having reported unfavourably. The expense of construction would be more than double that of the Salonica-Monastir section, viz., £16,083, against £7269 10s. per mile for the latter, and would necessitate the increase of the guarantee sought from the Government from £933 to £1930 per mile. The Acting British Consul-General at Constantinople regards the revival of the scheme in some shape as inevitable.

The railway from Manila to Dagupan continues to work well, and is very beneficial to cultivators in the neighbourhood of the line. The iron bridge over the Rio Grande, 492ft. long in three spans, has been recently opened, and will be of great benefit both to the country and line; the transport across the river hitherto having been made by ferries and temporary bridges, the latter of which have been twice swept away. The obstacles to erecting the new bridge were chiefly caused by the difficulty of finding a bottom to the river for sinking the caissons. A new line has been resolved upon from Manila to Batangas, and the Dagupan line will probably be extended to the province of Ilocos in the north, with which communication is very difficult.

The directors of the Midland Railway Company have accepted the tender of Mr. Scott, railway contractor, Newcastle, for the construction of a new railway from Chapletown to Ardsley. The line, starting from a point north of Chapeltown, forms a junction with the new Midland Railway from Wincobank to Chapeltown, and will pass between the Thorncliffe Ironworks and Chapeltown Works, continuing through a tunnel under the village of Warren and the Dolphin Wood, and emerging near Hood Hill. The route is then by Lidgett Colliery on to Wombwell, and from thence to Ardsley, joining the company's present system at that point. The length of line is about ten miles, and the cost estimated at £420,000. Double lines will be laid throughout.

A Board of Trade inquiry respecting the condition of the tramway in Uxbridge-road, in the parishes of Hammersmith and Acton, was resumed by Major-General Hutchinson at the Vestry Hall, Hammersmith, yesterday. The inquiry was held on the application of the Hammersmith Vestry and the Acton Local Board, and the evidence on their behalf was completed yesterday. Several witnesses expressed the opinion that the immediate reconstruction of the line was essential. In the course of the inquiry, the *Times* says, it was stated that a contract with respect to the undertaking, which is the property of the West Metropolitan Tramways Company, had been entered into, subject to the approval of the Court of Chancery. By this contract a purchaser agreed to reconstruct the line and alter it from a single to a double line, an outlay of from £25,000 to £30,000 being involved. The inquiry was further adjourned.

In Switzerland there were in operation at the close of 1893 2221 miles of railroads, of which 1860 miles were standard gauge and 277 miles narrow gauge there were forty-eight miles of rack railroads, twenty-six miles of street railroads, and ten miles of cable roads. There were under construction 156 miles of railroads. On the five principal lines 41 per cent. of the ties are of iron, 14 per cent. of oak, and 45 per cent. of other woods. Of the rails 75 per cent. are of steel, and 25 per cent. of iron. The rolling stock consists of 932 locomotives, 6417 passenger cars, 1263 baggage and mail cars, and 1887 freight car axles; the cars, which have partly two, partly three axles, being counted thus: Eighty-five per cent. of the locomotives, 67 per cent. of the passenger cars, and 78 per cent. of the baggage and mail cars are equipped with continuous brakes, and 59 per cent. of the cars are heated by steam. The *Railway News* says that in the latter part of last year a conference took place between the Jura Simplon Railroad and the contractors of the projected Simplon Tunnel, at which it was resolved to submit the new plans to an expert examination.

The Hawkesbury Railway Bridge which spans the "Australian Rhine," near Sydney, is said to be the largest of its kind in the Southern Hemisphere, and, as regards its foundations, one of the most remarkable in the world. The actual length of the bridge between the abutments is 2900ft., and it is supported by six piers, each resting on a caisson filled with concrete, and forming the most solid foundation possible. One caisson is 162ft. deep. The method of construction employed displayed considerable ingenuity. Each span was constructed on a large pontoon, 335ft. long, 61ft. wide, 10ft. deep, and provided with staging sufficiently strong to bear the whole weight of the immense mass of iron work, and high enough to enable the span on the pontoon being floated at high water into position, to clear the tops of the opposite piers, on which the girders rested when finally in place. *Indian Engineering* says that when the pontoon, which was provided with forty-four water-tight compartments, was complete with its staging, it was towed over a gridiron of piles and sills, in shallow sheltered water, and sunk, the exterior and interior valves being all left open, so that the water ran freely in and out at all tides. After the span was ready, the valves were closed, the water pumped out, and as the tide rose the pontoon floated and was towed into position between the two piers on which the span was intended to rest. As the tide fell, each end of the span descended into its proper place, and the pontoon and staging, released from its ponderous load, floated back to the gridiron.

## NOTES AND MEMORANDA.

Prometheum or titan metal, a new alloy containing 60 per cent. of copper, 38 per cent. of zinc, and 2 per cent. of aluminium, is said to possess a remarkable degree of resistance. A small quantity of sodium is added to the molten mass when being cast.

Gold occurring in a soft matrix is often distinctly crystallised, as also when it has been formed in a cavity whatever the nature of the veinstone. But, says the *Journal* of the Society of Chemical Industry, the gold contained in massive quartz as a rule is not crystallised, as may be seen by dissolving the silica away by hydrofluoric acid.

The transformers at the power transmission plant of the Oerlikon Electrical Works are interesting from the fact of their having an oil circulation. Taking the average load on each transformer as 170 kilowatts, and allowing a loss in conversion of 2 per cent., some 3·4 kilowatts is being lost, appearing as heat. In order to dissipate this heat, the oil is circulated through serpentine tubes immersed in a tank through which there is a constant flow of cold water. The circulation is effected with a pump.

Recently an experiment was made in America of casting concrete casings round piles for the purpose of resisting the attacks of the teredo insect. Iron tubes were clamped round the piles and driven to a depth of 12in. or so below the water bottom. The water inside the tube was then pumped out, and the space filled in with a mixture of one part Portland cement, two parts sand, and three parts gravel, well diluted. After three years some of these casings have been examined, and they are as hard as stone.

The sewerage system of Berlin, Germany, had a total length of 452·112 miles, of which 89·333 miles were brick sewers. It will doubtless be recalled that Berlin is sewered on the radial system, there being twelve sectors, from each of which a main sewer is to lead to one of the sewage disposal farms about the city. The *Engineering Record* says the first sector was finished in 1876, and eleven were completed by the close of 1893. On April 1st, 1894, there were 23,302 separate properties connected with the system, and the total area drained was about 13,815 acres, with about 1,600,000 inhabitants.

The mean daily motion of the air in 1893, as measured at Greenwich, was 270 miles, being eleven miles below the average of the previous twenty-six years. The greatest daily motion in the twelve months ending April 30th, 1894, was 942 miles on February 11th, and the least was forty miles on July 15th. The greatest pressure registered was 37 lb. on the square foot on December 12th, being the greatest which has been registered since the substitution of the flexible chain for the stiff copper connecting wire in 1882. The greatest pressure previously recorded was 31 lb. in March, 1888. A pressure of 35 lb. was recorded on February 11th.

During the twelve months ending April 30th, 1894, the highest air temperature in the shade at the Greenwich Observatory exceeded 80 deg. on twenty-eight days. It was 91 deg. on June 19th, 93 deg. on August 16th, 94·2 deg. on August 17th, and 95·1 deg. on August 18th. In the fifty-three years since 1841, higher temperatures have been recorded only twice previously—on both occasions in July. The lowest was 12·8 deg. on January 5th, the maximum on that day being only 19 deg., and the mean daily temperature 15·9 deg. The mean temperature on August 18th was 79·6 deg., being the highest mean value recorded in August since 1841. The mean temperature of January 5th was lower than any previously recorded since 1841, with two exceptions. The mean monthly temperature was above the average in all months excepting September, November, and January, 1894. In May it was 4·6 deg., in August 3·9 deg., in March 2·7 deg., and in April 3·8 deg. above the average. In November it was 1·5 deg. below the average.

The working of amber in Burma, the only locality in the Indian Empire where it is known with certainty to exist, is described in the *Times* as follows. By some superstitious rite a lucky place to dig is selected and a shaft made about 70ft. or 80ft. deep. If a vein is struck a side passage is made tracing it; at certain points lumps are found which are alleged to reach 1000 lb. in weight. A shaft is usually dug over these lumps, and the amber is extracted and sawn into the required sizes. A variety of amber used to be sold by the miners to the Chinese, and taken to China for use in making medicine. It is said that the mines were nearly exhausted many years ago. They are at present worked in a fitful and haphazard manner by the Kachins. A stone known in commerce as jade is extensively worked in certain districts of Upper Burma. Its colour varies from nearly gray to dark green. It is in universal demand throughout China. A variety highly prized by the Chinese is pale gray with bright apple-green spots, clouds, and veins. A block of less than a cubic yard in size was some years ago valued at £10,000 in Rangoon, and the Chinese are said to have offered £8000 for it. The Bhamo jade-producing country is far more important. It may be described as the district lying between the 25th and 26th parallels of latitude and shut in by the Chindwin and Mu rivers on the west and east respectively.

A paper on "The Isothermals of Ether" was recently read before the Physical Society by Mr. Rose Innes. Taking the important linear law $p = b\,T - a$ connecting the pressure and temperature of substances—liquid and gaseous—at constant volume, given by Ramsay and Young—*Phil. Mag.*, vol. xxiii., page 436—and subsequently confirmed by Amagat and Tait, the author has endeavoured to express the constants $b$ and $a$ in terms of the volume $v$. Using the results of Ramsay and Young's experiments on ether, because they extended over a large range of volume—1·9 to 300—the following formulæ were found to give the best approximation, viz.:—$b = \dfrac{751\cdot9}{v - 0\cdot9173\, v^{\frac{2}{3}}}$ and $a = \dfrac{23,300,000}{v^2 + 11\cdot05\, v^{\frac{5}{3}}}$. Tables of curves accompanying the paper showing that for volumes between 6 and 300 the agreement of calculated and observed values of $p$ do not differ more than can be accounted for by errors of experiments. For volumes less than 5 the formula for $p$ gives numbers quite wrong. In searching for a physical basis for the expressions for $b$ and $a$, the author puts $l^3$ for $v$ in the above formulæ, $l$ being the side of a cube whose volume is $v$. The expression for $p$ then becomes

$$p = \frac{R\,T}{l^3 - c\,l^2} - \frac{A}{l^6 + h\,l^5} \quad . \quad . \quad (3).$$

Writing the coefficient of T in the form $\dfrac{R}{l^3} \cdot \dfrac{l}{l - c}$, the author showed that this form might be expected if the molecules had finite dimensions, for the number of impacts on the faces of a cube would be increased in the ratio $\dfrac{l}{l - c}$, where $c$ is a quantity depending on the size of the molecules. Ingenious arguments suggested by Van der Waal's remark that his formula must not be pushed beyond the point where the actual volume is less than eight times the volume of the molecules, led the author to infer that for ether this limiting volume is somewhat above 6. Hence he would not expect his—Mr. Rose Innes'—formula to hold below this volume. The formula for $a$, the "internal pressure," is explained as a supposition that a "skin" effect exists between the matter of the vessel and the boundary layers. By clearing expression (3) in fractions, the author showed that the shapes of the isothermals are represented by an equation of the seventh degree in $l$, which cannot have more than three positive roots, and thence infers that isothermals are not necessarily represented by cubic equations as is sometimes assumed.

## MISCELLANEA.

A Board of Engineers has been appointed by President Cleveland to report on "What length of span, not less than 2000ft., would be practicable and safe for a bridge over the Hudson River at New York."

We read of a curious explosion on a locomotive. An engine driver was blown off his engine on the Great Western Railway, near Leamington, by the bursting of a hot water pipe. He died on the way to Leamington.

The new U.S. cruiser Minneapolis, sister ship of the Columbia, on her preliminary trial, burning anthracite coal, made 21·75 knots, as against the Columbia's 20·98 knots on her trial. This would indicate that she will surpass the 22·87 knot record of the Columbia.

The works in connection with the utilisation of the power of the Granier Falls, near Chambéry, are being pushed forward. A head of 2000ft. is available, which will yield 13,000 to 14,000-horse power. It will provide current for the electric lighting of Chambéry and intermediate localities.

Messrs. Siemens Brothers telegraph that the steamer Faraday completed the laying of the Commercial Cable Company's third Atlantic cable on Monday last. The insulation is perfect. During the laying of the cable no hitch of any kind has occurred, but operations have been much impeded by dense fogs.

We are informed that Messrs. J. P. Hall and Co., Blackriding Ironworks, Werneth, Oldham, have just satisfactorily completed electric light installations for the Manchester Ship Canal Company at the locks at Barton, Irlam, and Latchford. The installations each comprise arc lamps, dynamos, steam engines, boilers, &c.

Trials have recently taken place in Munich of a new bullet-proof cuirass, invented by a Hamburg armourer, Wilhelm Weber. The cuirass was fired at with a service rifle at a distance of ten paces, the bullets being shattered into small fragments. The cuirass weighs 11 lb., but the inventor states that it can be safely reduced to 8 lb.

The growth this year of gold production in Colorado is shown by the statements of the Denver Mint. In spite of the troubles at Cripple Creek the gold receipts for the month of May amounted to 431,934 dols., as compared with 99,786 for May, 1893—that is, they were considerably over four times the amount reported last year.

We are sorry to hear that the Woolwich Polytechnic is to be closed, in consequence of "financial difficulties." The handsome building was only erected two or three years ago, at an enormous expense. The trustees state that as they have themselves undertaken to be responsible for the liabilities of the institute, the debts will be paid in full.

We have received the second supplement to Sell's Telegraphic Directory of 1894. It contains some thousands of new registrations, cancellations, and other alterations effected during the quarter, and is sent free to all subscribers. Firms who have purchased the directory, and who desire to have sent to them these supplements, have only to notify their addresses to Mr. Sell.

We have received a geological sketch map of Western Australia, which should be useful to intending emigrants. The colouring shows at a glance the superficial composition of the earth, small patches indicating the presence of gold, copper, lead, tin and coal wherever they occur, according to the observations of H. P. Woodward, F.G.S., F.R.G.S. The map is compiled and published by Geo. Philip and Son, Fleet-street, London.

We have received a small two-page set of trigonometrical tables and formulæ, with explanations by sin. and cos. only. It is entitled "Trigonometry in a Nutshell," is handy in form, and can be easily carried in the pocket. The table gives the natural sines and cosines for every degree in the quadrant, and should be useful to many. It is arranged by Mr. W. H. Bidder, and is published by Messrs. Gale and Polden, Paternoster-row.

The Patent Equilibrium Piston Company, Cardiff, are making a piston on the principle of admission of steam to both sides of the packing rings. This is done by means of perforations in the top and bottom flanges of a carrier ring, through which the steam passes to both sides of the ring. Two rings are necessarily employed—which exert themselves alternately—that is, the ring next the side of the piston taking steam is always expanded by the pressure on that side, being released as soon as the return stroke is commenced.

In a resolution passed on the 4th inst. by the Hornsey Local Board accepting the resignation of Mr. Thomas de Courcy Meade, M.I.C.E., on his appointment as chief surveyor of Manchester, it was mentioned that during the thirteen years he has been engineer for the Hornsey Local Board the death-rate in the last ten years had been reduced from 13·6 per thousand inhabitants to 11·33, notwithstanding its immense growth and development. Mr. Meade's work had included many engineering and architectural works of considerable importance, and these, with the making of many miles of roads and works of sewerage, are represented by an expenditure of about half a million of money.

A thermometer for measuring very high temperatures is described in *La Nature*, the peculiarity of which is that quicksilver is replaced by a liquid alloy of sodium and potassium. The boiling point of this alloy is about 700 deg. C., and its freezing point is −8 deg. The graduation is made only from 200 deg. up to avoid the great length of tube which would otherwise be necessary. In taking temperatures it is necessary to heat only the reservoir and a small part of the tube, because there is a slight increase in the coefficient of expansion of the alloy as the heat increases, which will compensate for any error due to the lower temperature of the protected part of the tube. The thermometer has been designed by MM. Baly and Charley.

Large irrigation works are to be built in the Rio Verde Valley of Arizona by the Rio Verde Canal Company. The *Engineering Record* says that the contracts for the construction, which amount to about 2,000,000 dols., have been let to Langdon, Linton and Co., of Minneapolis, Minn., who say that about 110 miles of canal work will be done about Storage, a 150ft. dam will be built at the Horseshoe Bend of the Rio Verde, forming a reservoir of 205,000 acre-feet capacity, and a diversion weir will be built across the same stream about twelve miles from Mt. Dowell. Work will begin in a short time, and is to be completed in about eighteen months. About 400,000 acres of land will be irrigated by the system when complete.

Mr. Hall, the Inspector of Mines for the Liverpool district, states, in his report for 1893, that of the whole of the dusts tested, that from the Albion Colliery—Aberdare or Merthyr 4ft. seam or upper 4ft.—excels all others in violence and sensitiveness to explosion. He adds that this seam had the worst history of any in the kingdom, upwards of 1600 persons having been killed in it by explosions since the year 1845; indeed, "throughout the experiments one could not fail to be struck by the great violence and sensitiveness to explosion exhibited by the samples received from collieries with an unfortunate history as regards explosions." Mr. Hall's conclusions are dated August 20th, 1893, so that there was a delay of over three months in bringing the matter to the notice of the Home Office. The report was made "by desire of the Secretary of State to the Royal Commission on Explosions from Coal Dust in Mines."

## TO CORRESPONDENTS.

**Registered Telegraphic Address, "ENGINEER NEWSPAPER, LONDON."**

*** *In order to avoid trouble and confusion, we find it necessary to inform correspondents that letters of inquiry addressed to the public, and intended for insertion in this column, must in all cases be accompanied by a large envelope legibly directed by the writer to himself, and bearing a penny postage stamp, in order that answers received by us may be forwarded to their destination. No notice can be taken of communications which do not comply with these instructions.*

*** *We cannot undertake to return drawings or manuscripts; we must therefore request correspondents to keep copies.*

*** *All letters intended for insertion in* THE ENGINEER, *or containing questions, should be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever can be taken of anonymous communications.*

J. S. (Stockport).—*Letters addressed in accordance with your postcard have been sent you and returned through the Post-office. Send proper address.*

J. R. (Birmingham).—*The application must be made within seven months of the application for protection in the country in which the protection has been first secured. It does not, however, make it necessary that you should file a complete specification as early as you mention, and the publication of your invention here within the seven months does not invalidate your claim abroad in the countries within the International Convention.*

### SUBSCRIPTIONS.

THE ENGINEER *can be had, by order, from any newsagent in town or country at the various railway stations; or it can, if preferred, be supplied direct from the office on the following terms (paid in advance):—*

*Half-yearly (including double number)* .. .. £0 14s. 6d.
*Yearly (including two double numbers)* .. .. £1 9s. 0d.

*If credit occur, an extra charge of two shillings and sixpence per annum will be made.* THE ENGINEER *is registered for transmission abroad.*

*A complete set of* THE ENGINEER *can be had on application.*

*In consequence of the reduction of postage on newspapers to one uniform rate for any destination outside the United Kingdom, Foreign Subscriptions will, until further notice, be received at the rates given below. Foreign Subscribers paying in advance at these rates will receive* THE ENGINEER *weekly and post free. Subscriptions sent by Post-office Order must be accompanied by letter of advice to the Publisher.*

THIN PAPER COPIES—
*Half-yearly* .. .. £0 18s. 0d.
*Yearly* .. .. £1 16s. 0d.
THICK PAPER COPIES—
*Half-yearly* .. .. £1 0s. 8d.
*Yearly* .. .. £2 0s. 6d.

READING CASES.—*The Publisher has in stock reading cases which will hold thirteen copies of* THE ENGINEER. *Price 2s. 6d. each.*

### ADVERTISEMENTS.

*** *The charge for advertisements of four lines and under is three shillings, for every two lines afterwards one shilling and sixpence; odd lines are charged one shilling. The line averages seven words. When an advertisement measures an inch or more, the charge is ten shillings per inch. All single advertisements from the country must be accompanied by a Post-office Order in payment. Alternate Advertisements will be inserted with all practical regularity, but regularity cannot be guaranteed in any such case. All except weekly advertisements are taken subject to this condition.*

*Prices for Displayed Advertisements in "ordinary" and "special" positions will be sent on application.*

**Advertisements cannot be inserted unless delivered before Six o'clock on Thursday evening; and in consequence of the necessity for going to press early with a portion of the edition, ALTERATIONS to standing advertisements should arrive not later than Three o'clock on Wednesday afternoon in each week.**

*Letters relating to Advertisements and the Publishing Department of the paper are to be addressed to the Publisher, Mr. Sydney White; all other letters to be addressed to the Editor of* THE ENGINEER.

### MEETINGS NEXT WEEK.

LIVERPOOL ENGINEERING SOCIETY.—Friday, July 13th. Excursion to the Hydraulic Power and Electric Lighting Stations of the Manchester Corporation, by kind permission of the respective Committees, Mr. F. M. Evanson, Assoc. M. Inst. C.E., and Mr. C. H. Wordingham, Assoc. M. Inst. C.E., engineers.

# THE ENGINEER.

*JULY* 6, 1894.

## THE RAILWAY STRIKE IN THE UNITED STATES.

A MOST remarkable strike is in progress in the United States, and we learn without surprise that its headquarters are in Chicago; a marvellous mushroom city, in which are knotted together most of the principal railway lines of North America, and mainly inhabited by a mixed semi-savage population collected from every nation on earth. It is by no means easy to ascertain what the strike is about; the affair is hardly understood in New York, for example. All that is certainly known is that it originated in some dispute between the Pullman Car Company and its hands. In our impression for September 29th, 1893, will be found a very full description of the town of Pullman and the car works. These last employ about 6300 hands, whose average earnings are £120 per annum. The Pullman Company has contracts whereby none but its sleeping cars are allowed to run over 130,000 miles of railroad, and it owns and operates 2300 cars. All the long-distance travelling in the United States involves the use of sleeping cars; and consequently the railway companies are largely in the hands of the Pullman Company. It appears that the dispute between the company and its hands was not about wages. More than that we cannot say. The Pullman hands turned out and succeeded in getting the railway porters, drivers, signalmen, and shunters to assist them by refusing to handle Pullman cars. The immediate result was a stoppage of all traffic on several of the more important railways. Pullman is only a few miles from Chicago—a fact very much in favour of the strikers. The railway companies found no difficulty in getting fresh hands to take the place of the strikers. Then the strikers resorted to open warfare. The singularly inefficient magistrates called out a yet more inefficient posse of marshals, who were incontinently captured by the strikers. Chicago is dependent for its food supplies on the railways, and we are told that famine is at the gates. Chicago is also the centre of the meat trade—we had almost said of the world. As the packers can get no cattle or hogs, they are closing their works and discharging their hands by the thousand. A telegraphic despatch by the *Times* correspondent states that "The various railroads that bring cattle are pasturing thousands of animals along their lines, being unable to enter the city. The North-Western has 8000, the Burlington 6000, and the Rock Island 20,000 pasturing." It is clear that a small further development will paralyse the whole railway system of the United States. A body of several thousand men having obtained possession of the railways will prevent them from being used until such time as their demands have been satisfied. Cities will be reduced to starvation, trade ruined, and the country reduced very much to the condition in which it would have been placed by an invading army.

The strikers are apparently determined that they will win at all costs to the community at large, and the question very naturally arises, what are the limits to the operations of the "labour party" of the United States? If they are successful in this instance, there is nothing to prevent them from proceeding further, and so far as can be seen, they may take possession of not only the railways but the factories. Under the modern systems of civilisation, any interference with transport can inflict fearful evils on a country. If pushed far enough, famine and its natural concomitant pestilence can be forced upon a nation. Under these conditions it is evident that the law of self-preservation will assert itself, and history tells us that the people of the United States when they are once really roused do not spare. The supreme power of the nation can only be made to act with difficulty. Each State is a law to itself, and to secure action at once harmonious and prompt is by no means easy. The President of the United States has, however, adopted the one course open to him. He has insisted that the national mails must be carried without interruption—strike or no strike; he has declared the strikers to be "rebels," and he has ordered the despatch of troops to protect those who are willing to take the place of the strikers. The United States Court at Chicago has granted a general injunction against the railway strikers, prohibiting all interference with mail trains, and also with all trains crossing the State boundaries. The injunction covers Illinois, Indiana, and Wisconsin. But this injunction will be a dead letter unless it be enforced, and it seems to be more than probable that it cannot be enforced without much fighting. The situation is, it will be seen, very different from that brought about by a strike affecting private interests only. If in a certain community of one hundred individuals any transaction affects, say five, the remaining ninety-five will care very little about the matter. Should it inconvenience ten, the remaining ninety will begin to talk and say that something should be done. If it concerns twenty, then the remaining eighty will probably exert themselves a little to settle the affair. If it affects eighty persons out of the hundred, they will very quickly and suddenly take the trouble necessary to bring about a more comfortable state of life. Now a strike in an ironworks, such as that at Messrs. Carnegies' last year, affects a very small percentage of the community; but a great railway strike affects a very large proportion. The people say that as for the dispute between Messrs. Pullman and their hands they may fight that out as they please, but they must not interfere with the national railway traffic. The result has been that troops have been called out, and the strikers will be beaten. We read of Gatling guns commanding the streets in Chicago, and already Mr. Debs, the leader of the strike, has announced that a settlement is possible. This is all quite as it should be, but the mistake so constantly made by Governments of all kinds is that they assert their power too late. Violence of all kinds is illegal. If men are found burning or destroying the property of other people, or threatening, beating, and terrifying those who wish to work, then punishment should follow swiftly and surely. And it is all the more necessary that the arm of the law should be felt promptly, because the working population of the United States is so largely composed of men of all nationalities except American. No one who watches the signs of the times can fail to perceive that of late years strikes have been accompanied to an unprecedented extent by crimes of violence. This is an evil fact—a thing of bad omen. In this country, at all events, the law is satisfactory enough, its enforcement is not. In the United States the law is defective. Its enforcement is generally tolerably complete and sweeping. An improvement would be effected by amalgamating the two systems. The United States might learn something from us—we might learn something from them, and the progress of the present strike will be watched just now with special interest in this country for reasons which should be so obvious that it is not necessary to specify them.

## METROPOLITAN WATER SCHEMES.

THERE is every indication that the supply of water to London will be made a very urgent question in the Parliamentary session of next year. The County Council are devising plans for a supply to be drawn from some distant source, apparently in Wales, and are at the same time entering on the preparation of eight separate Bills, providing for the transfer to the Council of the undertakings of the eight metropolitan water companies. On the other hand, those of the companies who take their supply from the Thames, are consulting as to the preparation of a scheme which shall fulfil the requirements laid down by the recent Royal Commission, and for which the sanction of Parliament will necessarily have to be sought. In the session now being held, the Bill of the Southwark and Vauxhall Company for enlarged storage works above Hampton, having passed through the Commons with some amendments, has been read a second time in the House of Lords, together with the Bill of the East London Company, authorising an extension of their works in the Lea Valley. The Thames Conservancy Bill, which is connected on some important points with the question of the water supply, is vigorously opposed in the House of Commons by the London County Council, who are moving for its re-committal, accompanied by sundry instructions.

The plan devised by Messrs. Hunter and Fraser for a series of storage reservoirs in the neighbourhood of Staines is understood to be still entertained by one or more of the water companies, though on a reduced scale; and there is at least a probability that a Bill on this basis will take its place among the rest in the coming session. Some remarks made last week in the House of Lords by Lord Balfour seem to point in the direction of this project as a "comprehensive scheme" to be brought forward next year, and for which the way should be left open. As if anticipating the further investigation which the subject thus appears destined to undergo, Dr. Frankland's annual report to the Registrar-General, which has just been issued, relative to the water-supply of the metropolis, contains a much larger amount of information than usual, although it is a document always prepared with much care and elaboration. Before discussing Dr. Frankland's report, we may observe that, according to a statement which immediately precedes it, the average daily supply of water to London last year exceeded 196 million gallons. This is a very large amount, greater than the average of the previous year by nearly 10 million gallons per day. The hot dry weather which characterised so large a portion of last year, doubtless had its effect in an increased demand on the services of the water companies. The growth of the population constantly tells in the same direction. Registration London is estimated to have added quite 42,000 to the number of its inhabitants last year, and this fails to include the large addition which must have taken place in the outer area supplied by the London water companies. That measures must needs be adopted to meet the ever-growing demand cannot be denied, and it is to be hoped that the Bills now promoted by the water companies will receive the approval of Parliament, though impaired by the strange embargo that the statutory rights of the companies to abstract water from the river shall not be enlarged. It is tolerably certain that the companies will not pump and filter more water than they can help; while, on the other hand, if London wants more water than the law allows, the supply must be given. London will not endure drought by Act of Parliament.

Discussing the quality of the water supplied to the metropolis, Dr. Frankland admits that organic matter of animal origin enters both the Thames and the Lea above the points whence the supply is taken. But he goes on to say it is gratifying to find, as the result of recent researches, that the zymotic poisons are rapidly destroyed in running water exposed to sunlight, "so that the most minute microscopic inspection of the water at the intakes of the various companies has hitherto failed to discover a single pathogenic germ." Even supposing such germs should arrive in a living condition at the intakes of the companies, efficient sand filtration would ultimately arrest their progress. This is asserted as an established fact—provided, of course, that the filtration is conducted in a proper manner. "Efficiency" in this case is the grand condition of safety. How far this state is arrived at may be inferred from the extent to which germs of all kinds are excluded. A great destruction of bacteria is also effected by storage preliminary to filtration. As an instance, it is stated that while the water at the intake of the East London Company contained, on the average of the year, nearly 10,000 microbes per cubic centimetre, the same water, after storage for fourteen days, averaged only 1200 microbes per cubic centimetre, to be afterwards virtually extinguished by the filter beds. The Chelsea Company, with reservoirs affording 14·7 days' storage, and filter beds surmounted by 4ft. of sand, removed on an average more than 98 per cent. of the microbes, and as a maximum result excluded them all. The West Middlesex Company, with less than 3ft. of sand, attained an average removal of nearly 99 per cent. of the microbes, and a maximum of 99·94. The lowest number of microbes found in the West Middlesex water was five per cubic centimetre in December, while the raw water of the Thames at the intake contained at the same time 6316 microbes in the cubic centimetre. The maximum removal effected by the Southwark and Vauxhall Company was 99·92 per cent., with an average of 98. Dr. Frankland makes the remark that efficient filtration does not seem to depend essentially on the thickness of sand which covers the filter beds—an instance of this kind being afforded by a comparison between the West Middlesex and the Chelsea water. The New River Company, with less than two feet of sand, contrived to deliver throughout the year water possessing a high degree of bacterial purity. It is suggested as probable that a regular rate of filtration throughout the twenty-four hours is of much more importance than the thickness of the filtering medium. Even this conclusion somewhat fails, for the New River Company works its filters at a higher rate than that employed by any of the other companies, except the Lambeth, and yet stands at the head of the filtering companies as regards bacterial purity, never having more than thirty-seven microbes per cubic centimetre during the year, the prescribed limit being 100. One consideration must not be lost sight of—that the bacterial efficiency of sand filtration depends, to a very large extent, upon the formation of a thin film upon the surface, derived from subsidence of suspended particles in the raw water. The entire subject is undergoing further investigation, and until the experiments are complete Dr. Frankland refrains from drawing any definite conclusions, though offering certain remarks based on the existing data.

The general rule that cholera travels up the stream instead of down, has sometimes been used as an argument to show that water is not the vehicle of contagion. Dr. Frankland offers a fair explanation of the circumstance, and one which carries a distinct warning with it. Cholera, he observes, almost always arrives at the mouths of rivers by sea. The estuary becomes polluted, and the infecting matter is carried up by the tide. The barges create the subsequent danger, it being the habit of the bargemen to dip their drinking water out of the river at any point where it ceases to be brackish, and then to consume the liquid without any filtration. They thus become infected, and convey the zymotic poison up the stream as far as the river is navigable. Canals may in some respects open up a still further inlet for the transmission of the disease. The dietetic use of raw or imperfectly filtered water derived from open streams is at such times fraught with extreme danger. But experience gained on the Continent has shown that filtration can be made effectual as a barrier against cholera. If this disease should menace England, it becomes imperative that all public supplies of water should be protected against the inroads of the zymotic poison. In London this is being accomplished, but the difficulty will be to make local authorities and small water companies perform their duty as guardians of the public health. The great majority may do well, but there will be a stupid minority capable of working widespread mischief. Yet the knowledge which is now gained will be of inestimable value, as showing where the danger lies. Dr. Frankland has given himself earnestly to the subject, and feels that the bacterioscopic examination of the water supplied to vast communities like London, has become an investigation of the highest importance from a hygienic point of view. He is therefore each year devoting an increased amount of attention to the bacteriological character of the various waters supplied to the Metropolis. The inhabitants of London and its environs may be congratulated on the fact. Much needless alarm is thus prevented, and at the same time wise and precautionary measures are initiated, such as were unknown to a previous generation.

## ABSOLUTE ZERO.

THE discussion on thermodynamics which has proceeded for some weeks in our correspondence columns becomes more interesting. How can it be otherwise when we find such redoubtable physicists and mathematicians as Dr. Lodge, Professor Alexander, Mr. Mansel, Major Basevi, and Mr. Donaldson joining issue? Nor is the discussion carried on without humour. Dr. Lodge frankly confesses that a chapter in Professor Alexander's book has "fairly stumped" him. Professor Alexander retaliates and explains that he has set a mathematical trap for Dr. Lodge "to draw him," and chuckles with delight at the fact that he has accomplished that feat. Dr. Lodge has written not one but two articles on entropy, a thing concerning which it is not too much to say that engineers are densely ignorant, which is not after all so astonishing as at first sight it might appear to be when we remember that Clerk-Maxwell hailed the advent of entropy with delight, and wrote an explanation of it which he had to withdraw in a succeeding edition of his book when it was explained to him that the word meant something entirely different from what he supposed. Then we have various other correspondents asking for explanations or disputing the soundness of views expressed by more or less shining lights in more or less valuable text-books; and so at last an outsider may not unnaturally ask what the discussion is about, and how it comes to pass that there is any discussion at all. It may serve a good purpose if just at this stage we endeavour to clear the ground a little, and enlighten our readers in general on the nature of the *casus belli*.

It is very erroneously asserted that the science of thermodynamics is exceedingly simple. Nothing can be further from the truth. It very closely resembles Lindley Murray's grammar. There are a lot of rules, which are easily remembered. All would be well if Lindley Murray on the one hand, and thermodynamics on the other, stopped there. They do not stop there; to every rule there is an exception, sometimes two or three. This complicates matters frightfully. To cite an instance, let us take Marriotte's law. It is beautifully simple. The volume and the pressure of a gas multiplied by each other always give the same result. Double the pressure, half the volume, and so on. In other words, the pressure of a gas varies inversely as its volume. This is simplicity itself. But unfortunately it is true only of what does not exist on earth—a perfect gas, and it is not true of that save under special conditions. The law is all right, and the exceptions are all right, but to combine the two is not a task always performed satisfactorily for all gases. If our readers will bear the fact steadily in mind, that the so-called laws of thermodynamics are based partly on experiments, partly on theories which are really more or less clever guesses at truth, partly on mathematical deductions from assumptions and deductions, they will be in a position to understand how wide is the door that stands open for controversy. It is, of course, useless to assert that there is no door open. The facts are all the other way.

Recently much of this discussion has turned on the question of absolute zero; that is to say that state of matter when there is absolutely no heat present in it. Here we fall at the outset on a stumbling-block. No one has the smallest idea what heat is, and no one knows what temperature is. When it is said that heat is something that burns your fingers, and temperature something that makes the thermometer work, we seem to have summed up human knowledge on the subject. Now when the physicist speaks of absolute zero, he means absolute absence of temperature. No one can tell, however, whether the total absence of temperature would be attended with the total absence of heat. Until quite recently anyone who attempted to question the accuracy of Lord Kelvin's dictum that absolute zero was − 273 deg. C., would have been, metaphorically, burned as a heretic. It appears, however, that Mr. Donaldson and others are quite prepared to risk the stake. We shall first state the fundamental basis of the absolute zero theory. It is Gay-Lussac's law:—"The coefficient of dilatation of a perfect gas under constant pressure is constant and independent of this pressure." If this law is not true, then it is certain that − 273 deg. C is not absolute zero.

Let us proceed next to explain what it all means, and in the first place we cannot do better than quote a passage from Clerk-Maxwell. Having described—page 49 of the fifth Edition of the "Theory of Heat"—an air thermometer and its graduation, he goes on, "To determine the reading at the bottom of the tube is a very simple matter. We know that the distance of the freezing point from the bottom of the tube is to the distance of the boiling point from the bottom in the proportion of 1 to 1·3665, since this is the dilatation of the air between the freezing and the boiling temperatures. Hence it follows by an easy arithmetical calculation, that if, as in Fahrenheit's scale, the freezing point is marked 32 deg. and the boiling point 212 deg., the bottom of the tube must be marked −459·13 deg. If, as in the Centigrade scale, the freezing point is marked 0 deg. and the boiling 100 deg., the bottom of the tube will be marked −272·85. This, then, is the reading at the bottom of the scale." Again, the range of a thermometer may be expressed in terms of work done on a substance by each addition of heat, in a way fully explained by Maxwell at page 156 of the "Theory of Heat," and it is this consideration that brings J into our correspondent's letters. We may now try to simplify all this. Let us suppose that we have in a bag a large number of marbles—how many marbles we cannot tell; but we can put the bag in a pair of scales, and we find that its contents weigh 1 lb. We assume that all the marbles are of the same size and weight. We have plenty more besides those in the bag. We now add, say, ten marbles to those in the bag, and we weigh the whole again. We find that the bag now weighs 1 lb. and $\frac{10}{273}$ of a pound. We add ten more marbles, and we find that the bag weighs 1 lb. and $\frac{20}{273}$ of a pound. We then have no hesitation in saying that there are 273 marbles in the bag to begin with. Now let us take another case. We have a thermometer, the stem of which is equally graduated into, say, 300 spaces. We apply heat, say, for 15 seconds, and the mercury rises one degree; then for 15 seconds more and it rises another degree, and so on. It is assumed that the quantity of heat poured into the thermometer is directly proportional to the time of action. The mercury stood at the 273rd mark to begin. A certain increment of heat raised it one degree, and so on. But it is quite natural to assume that if we took out heat in the same way, after we had removed 273 deg., there would be none left. These two methods are not identical in their method of teaching. Taken together they explain the kind of reasoning by which the notion of absolute zero was arrived at. Now, to apply Gay-Lussac's law to all this we have only to conceive that we have a perfect gas occupying a given volume, under a piston. If we apply heat the gas will expand and the piston will rise. Let the rise be $n$; then by doubling the quantity of heat supplied the rise will be doubled, and we shall have the total rise as $2\,n$, and so on, equal increments of heat giving us $1\,n$, $2\,n$, $3\,n$, and so on. But, on the other hand, if we abstract heat we shall have successive descents of the piston $1\,n_1$ $2\,n_1$ &c.; and it is obvious that if we continue the process of abstracting heat, we shall at last come to a point when the gas will have no volume at all and no heat. As to whether this point is reached at 273 deg. or not, depends on the length of the $n$ divisions to begin with. On Fahrenheit's scale the divisions are 460. All this is plain sailing; and provided it is conceded, as we have said, that Gay-Lussac's law is true, then absolute zero is 273 deg. below the arbitrary zero of the Centigrade scale. If, however, the amount by which the gas expands or contracts for a given addition or subtraction of heat varies, then the whole calculation is upset. If, for example, our marbles were all of different weights, it would be quite impossible to ascertain by any conceivable process of weighing how many marbles there were in the bag to begin with. It is here that Professor Alexander, Mr. Donaldson and Major Basevi enter their protest, directly or indirectly. They maintain that Gay-Lussac's law is not true without important qualifications; that any air or gas thermometer which it is possible to construct does not contain a perfect gas, and that the coefficient of dilatation is not constant, but variable in a way and to an extent which has not been determined with accuracy. And here it is proper to remark that the question becomes complicated yet further by the importation of the term specific heat. That in its simplest form means the *quantity* of heat required to raise the temperature of a given weight of any substance one degree. In other words, specific heat is the heat needed to bring about a definite change in a body, such as a rise in temperature. We have then to consider two points in dealing with Gay-Lussac's law. In the first place, assuming that the specific heat of a gas remains constant at all temperatures, will its coefficient of dilatation vary? In the second place, assuming that its coefficient of dilatation remains constant, will its specific heat vary? That is to say, will the same quantity of heat invariably produce the same rise in temperature? Nothing is easier than to ring the changes on these points. Thus it may be said that for nitrogen, for example, equal additions of heat neither effect equal changes in temperature nor in dilatation; or it may be said that while equal additions of heat produce equal changes in temperature in all regions of the scale, they do not effect equal changes in volume. But above and beyond this question comes another to make confusion worse confounded. Is it certain that when a body has lost all its temperature it must have lost all its heat? We know that heat may be poured into water, for example, or into ice, without producing any effect, however minute, on the thermometer. Major Basevi argues with sufficient plausibility that water at absolute zero could have no specific heat whatever.

It will be seen, then, that while the deduction of the absolute zero from a thermometer so constructed that equal additions or subtractions of heat invariably produce equal effects, is the easiest thing imaginable, the carrying of the deduction into practice is full of difficulties; so full of them, in fact, that it would be quite wrong to assume it certain that if Professor Dewar could succeed in getting a temperature of − 273 deg. C. on any thermometer, it would be beyond all doubt that the substance so cooled down would be entirely devoid of heat. It may be said that, after all, this question of absolute zero is one of very little practical importance. That is not quite true, however. It is only necessary, for example, to read such papers as those which Dr. Lodge has contributed to our columns, to understand how important a part is played by this same absolute zero. What will be the ultimate result of the discussion of the subject in our columns we cannot pretend to say. We venture to think, however, that it can hardly fail to place the matter on a firmer basis than it has hitherto possessed, and that will be a distinct gain to science.

## TYNE DUES AND STEAMERS.

AN agitation of some moment seems commencing on the Tyne for the reduction of dues on steamers frequenting the port. It is probably increased by the fact that the dues on the neighbouring river Tees have been reduced with good results both to the conservancy of the river and to the steamers trading thereto; but it unquestionably arises from the depressed state of shipping, and the fact that some of the heavy works needed on the Tyne are about completed, and the steamship owners believe that there is now not only the need for lower dues but the possibility of obtaining them. The heavy nature of the imposts on steamers may be conjectured when it is stated that the dues on a steamer a little over 1500 tons net register, which entered the river for dry docking purposes only, amounted to £30 15s.—more for river dues, pilotage, and towage than the cost of the dry docking. It is clear that charges such as these on steamers that actually use none of the public docks or wharves must militate against the interests of the port, and must tend to drive some of the work to places where the dues are less. Vast engineering works have been in progress on the Tyne, and during their continuance heavy dues were paid with some cheerfulness; but the great walls at the mouth of the Tyne are now practically completed, and with a reduced capital expenditure there is now the strong desire for some reduction of the imposts, so as to make the great coal river a cheaper port, and thus to give relief to steam shipping at a time when it needs every aid it can get to enable it to work without loss. One of the most marked features in the trade of the Tyne of recent years is the decay of the general trades, and that decay is in some degree due to the change from the small steamers that could take full cargoes to the very large boats that can only get part cargoes. As the dues are charged on the tonnage of the vessel, it is evident that there is a difference between the two methods, for in the small steamer the tonnage of goods was greater than that on which dues were paid; whilst the large vessel pays dues sometimes on threefold the tonnage of the goods taken on board. Hence goods are sent by rail at times to other and larger ports, where there is the greater likelihood of a full cargo, and ports such as the Tyne suffer in consequence. Under the circumstances, then, there is a strong claim for abatement which is being pressed, but the concession of which is doubtful. None the less, however, is the claim of the steamship owner important, and one that can scarcely be overlooked in the growing competition of the ports.

## THE WATER SUPPLY OF PARIS.

THE Anderson Revolving Purifier Process, by means of metallic iron, is meeting with great favour for the treatment of the river water supplied to Paris and its suburbs. A plant purifying over a million gallons a day has been steadily at work for nearly two years at the Boulogne-sur-Seine waterworks of the Compagnie Générale des Eaux — which are situated below the city—and gives most satisfactory results. The General Council of the Department of the Seine, after a long and careful investigation, has abandoned the proposal to obtain a supply of spring water for the suburbs of Paris in favour of the scheme put forward by the Compagnie Générale des Eaux to deliver purified Seine and Marne water to the fifty-seven Communes in their district. The new supply, amounting to 15 million gallons a day, will be drawn from the Seine and the Marne above Paris and purified by the Anderson process; the Compagnie Générale des Eaux undertaking to remove 99 6 per cent. of the microbes in the original water. The work under this contract is now in hand, and is to be completed by the end of 1895. In addition to this a further portion of the suburbs included in the territory of the Compagnie des Eaux de la Banlieue is to be supplied with some 7 million gallons a day of purified Seine water taken from the river at Suresnes. A third scheme has also now been completed for a supplementary supply of some 9 million gallons daily for the city of Paris itself. The source of this supply will be the river Marne, and the necessary purifying and filtering plant will soon be put in hand. Within a short time, therefore, some 31,000,000 gallons of river water, purified by the Anderson process, will be supplied daily to Paris and its suburbs. A series of twenty-two analyses of samples taken at Boulogne-sur-Seine—at dates unknown to the Cie. Général des Eaux — by Dr. P. Miquel, of the Paris Municipal Laboratory, shows an average reduction of bacteria amounting to 99·57 per cent. Of these twenty-two analyses, which extended over a period of six months, seven showed a reduction of over 99·8 per cent., and twelve of over 99·6 per cent.; the rate of infiltration averaging 6in. per hour. The bacterial purity of the purified Seine water taken below Paris was greater than that of the spring water of the Vanne in the case of nine samples, and equal to it in the case of two. The average of the twenty-two samples gave a lower figure than was obtained from the average of the bacterial analyses of any of the spring waters supplied to Paris, with the exception of the Vanne, to which it nearly approached.

### MINING IN YORKSHIRE AND LINCOLNSHIRE.

MR. F. N. WARDELL, F.G.S., H.M. Inspector of Mines for Yorkshire and Lincolnshire has issued his report for 1893. It is of exceptional interest, as the loss of life in his important district during the year reached a total of 218. This was caused chiefly by a great calamity at Combs Colliery, an explosion of fire-damp there involving the deaths of 139 persons. At Sharlston Colliery three lives were lost from a similar cause. The most fertile source of fatalities is that recorded under the heads of "Fall of roof and sides." Mr. Wardell states that this is nearly always the most serious cause of mortality. The loss of life from falls amounted in 1893 to 37, the result of 35 separate accidents, the numbers in the previous year being 45 and 43 respectively. Owing to the long cessation of work at the collieries experienced during the year through the strike, the output of coal was very much reduced, the weight brought to bank in 1893 having been 15,951,843 tons, or a decrease of 7,233,665 tons on the output of 1892. The amount of fireclay raised in 1893 was 190,271 tons, or a decrease of 52,830 tons. In 1893 164,108 tons of ironstone were produced, representing a decrease of 22,005 tons as compared with 1892. Shale and other minerals exhibited a reduction of 17,263 tons. The total amount of mineral raised in 1893 was 16,383,309 tons, or a decrease of 7,325,763 tons on the previous year. The total amount of mineral raised in the United Kingdom in 1893 was 175,236,857 tons, which is a reduction from the total of the previous year of 16,718,051 tons. The number of lives lost in and about mines in the United Kingdom during 1893 was 1060, or an increase of 44 over the number in 1892. 683,008 persons were employed in the production of minerals in the United Kingdom, a number which represents a decrease of 634 on those employed in the year preceding. The proportion is thus given as one death to every 644 persons employed, and 165,318 tons produced. In the Yorkshire and Lincolnshire districts, owing to the Combs Colliery calamity, the proportions are less favourable, viz., one death to every 407 persons employed, and 75,103 tons produced.

### MR. LUDWIG MOND AND THE ROYAL INSTITUTION.

MR. LUDWIG MOND, well-known in the world of chemistry for his research, has purchased the freehold of No. 20, Albemarle-street, close to the Royal Institution building, and this he proposes to give to the Royal Institution, after he has fitted it up as a research laboratory. It is to be known not as the Mond, but as the Davy-Faraday Laboratory. We need scarcely add that no pains will be spared or expense avoided in the endeavour to make this establishment the most perfect of its kind. When we bear in mind the great cost of such apparatus as that used by Professor Dewar in his interesting investigations into the properties of gases, we may form an idea of Mr. Mond's munificence. The laboratory is to be placed under the control of a committee, nominated by the managers of the Royal Institution from among themselves, and reporting to them. While the laboratory will have a competent chief of its own, devoting all his time to its work, Mr. Mond desires that the resident professor at the Royal Institution should accept the position of director. The laboratory is to be free to all persons, without distinction of sex or nationality, who, in the opinion of the manager of the Institution, are fully qualified to undertake scientific investigation, preference being naturally given to those who have actually done original work. It is a noble gift not a little enhanced by the self-effacing manner of the giving.

## LITERATURE.

*Sewage Disposal.* By Mr. W. SANTO CRIMP. London: Charles Griffin and Co. Second Edition. 1894.

THIS is the second edition of a work on sewage disposal which the author published in 1890, and contains much useful information that will be appreciated by engineers who are engaged in advising about sewage disposal. We think the book could have been condensed by the omission of the verbatim references to the reports of ancient date, which are now only of interest historically. The introductory portion of the book is devoted to a summary of what has been attempted in regard to the prevention of pollution of rivers by sewage or manufacturing refuse, the data being mainly derived from the reports of the River Pollution Commissioners of 1865 and of 1868. The time that has elapsed since the recommendations contained in these reports were pressed on the notice of the public, and the knowledge that legislation in the direction of enforcing the recommendations has been far too permissive, leaves one to hope that Parliament may soon find time to pass drastic measures to take the place of the existing permissive statutes.

The author devotes a chapter to the consideration of the rate of the flow of sewage from houses and factories, and refers to the conclusions which were arrived at by the referees who reported upon the scheme for the main drainage of the metropolis. He states that those conclusions are confirmed by his own observations as the engineer in charge of the Metropolis Northern Outfall Works of the London County Council. He agrees with the opinion of the late Mr. Gordon—whose untimely death when chief engineer of the London County Council was greatly deplored—who, when at Leicester, found that 70 per cent. of the daily flow may be discharged in twelve hours. The calculation generally adopted is that 50 per cent. of the maximum flow may pass to an outfall in six hours. The proportion to be adopted must necessarily be governed by the area which the sewers drain. Provision for a smaller volume could be made in an outfall sewer receiving sewage from various contributing sewers over an extensive drainage area, from which the heavy flow due to sudden storms could not arrive at the outfall simultaneously, contributions from distant parts of the district arriving later at the outfall than those from districts that were nearer, or where the steeper gradients of the sewers brought the sewage more rapidly to the outfall. In the case of sewers which have to serve a small area the conditions would be different, and the risk of flooding would be greater than would be the case with large areas, if the lower calculations above referred to were adopted. There is a great need of careful calculation for, and skilful arrangement of, a system of sewers. This is too often not recognised by local authorities who entrust the sewerage of their districts to those who have had no previous experience in this important branch of practice.

The author points out the wide variations that occur in regard to population and area, seven to eight people to the acre being taken in suburban parts of the metropolis, whilst from 200 to 300 to the acre represent the population in thickly-populated parts. Some data are given as to the basis which was adopted for sewering the metropolis, and the author gives some information as to the discharging capacity of the metropolitan northern outfall sewer. In 1857 Messrs. Bidder, Hawksley, and Bazalgette calculated the size of this sewer by the formula $V = \sqrt{1·6. H.F.}$, where $V$ = velocity in feet per second, $H$ = hydraulic mean depth in feet, $F$ = flow in feet per mile. The author found by gaugings that the actual discharge was 30 per cent. more than the calculated one. He does not, however, give the data on which this conclusion is based, as the sewer might have been under pressure by the sewage rising in manholes, &c., so that the sewer was gorged. We wish the author had devoted some part of his book to the important question of the flow of sewage, and the discharge from sewers, which at the present time require to be better dealt with than by resorting to the published tables that are based on old and erroneous formulæ. The author had good opportunities of observation during the time he had charge of the northern metropolitan sewers.

Information on the flow of water in culverts and channels is given in the work by Professor H. Robinson, on "Hydraulic Power and Hydraulic Machinery," which was recently reviewed in THE ENGINEER, vol. lxxvi., page 616.

Much useful information is given in regard to the sizes of settling tanks for chemical precipitation processes, and detailed descriptions of the various systems are afforded which furnish a complete historical record. This, however, might have been condensed, as several of the systems are now obsolete. Presses for converting sewage sludge—which used to be the bug-bear of precipitation works — into portable material are fully described and their construction illustrated. The tables showing the composition of sewage sludge that were prepared by Dr. Wallace in 1879, and by Dr. Munro in 1887, are given, as well as the more recent analyses by Mr. Dibdin of pressed sludge from the Crossness Outfall Works.

Numerous sewage farms are described in detail, and the practical operations are entered upon very fully. The Berlin Sewage Farm is referred to as an example of a skilfully-designed and successful undertaking, the data being based on a paper by Mr. Roechling, which was read before the Institution of Civil Engineers. The book is evidently the outcome of much careful compilation, and the author deserves thanks for the trouble he has taken.

## PARLIAMENTARY NOTES.

*Government shipbuilding contracts.*—A return was made to this subject on Friday, when Mr. Macdonald and Mr. Keir-Hardie applied further questions to the Secretary of the Admiralty. Sir U. Kay-Shuttleworth said:—"The statement that the tender sent in last December by the Thames Ironworks Company for the Powerful was only £5000 in excess of those of the successful competitors is not correct. The difference was much larger. The Thames Company also offered an alternative and lower price, but not as much as £50,000 lower than their tender for the ship as designed, upon a proposed design of their own with different boilers. But the introduction of tubulous boilers was an integral part of the design for which tenders were invited. The tubulous boilers as adopted in the Powerful and Terrible are not experimental. But it is useless to quote or discuss a tender upon a design not proposed or wanted by the Admiralty. Any tender that could be entertained must be in accordance with the design. I now turn to the case of the tenders for two battleships. When these had been examined in March, an offer was made to a Clyde firm, because that firm was amongst those who had tendered lowest. The same offer was made at the same time to another of those who had tendered lowest, the latter firm accepted; the former declined. A similar offer was then made to a third firm, also one of the lowest tenderers, and accepted. The Thames Ironworks Company were not among the lowest tenderers; therefore no such offer could be made to them. Nor was any offer made to any firm not in the tendering list. After both the battleship contracts had been placed, the Thames Ironworks Company made proposals to build a battleship for the amount of the lowest tender or somewhat less, and asked for the transfer to them of the order for one of the battleships provided for in the dockyard programme. This proposal could not be entertained, because it would have deranged that programme and left one of the dockyards with insufficient work for the employment of its workpeople, thus necessitating their discharge in large numbers. The amounts of tenders which are not accepted cannot be published without a breach of confidence. But as I have before stated, a return will be presented as soon as all the contracts are complete, which will give the amounts of the actual contracts made, as well as the name of each contractor." Sir Ughtred declined to state how much the tender was in excess of the tender of the Clyde firm, and in reply to Mr. Allan he said that the royalty for the French boilers was part of the price the Admiralty had to pay for the work. Then came a struggle by Mr. Keir Hardie in the interests of the unemployed on the Thames. Had not nearly the whole of the Thames Ironworks men been thrown out of employment for nearly two years through the withdrawal of Government work? The Secretary to the Admiralty said everything had been done that could be done. The company was always invited to tender, but it must take its chance like everybody else. He was sorry that men on the Thames were out of work, but that was also the case in other parts of the kingdom, a statement which was cheered. A discussion then followed as to the practice of the Government in dealing with tenders. Mr. Noble asked whether it was the custom to allow tenderers to revise their tenders and so to bring them down below a tender which had been accepted. Sir U. Kay-Shuttleworth said such a course would be most objectionable. Sometimes, of course, there were circumstances which made the lowest tenderers unacceptable. Mr. T. G. Bowles asked if the company in question were among the lowest tenderers? Sir U. Kay-Shuttleworth: They were not only not among the lowest, but they were very much higher than those whose tenders were accepted. Lastly, in reply to Mr. Benn, Sir U. Kay-Shuttleworth said:—"The practice of the Admiralty, when ships are to be built by contract, is to invite tenders from selected firms and to give the preference to those who tender lowest, provided that they fulfil all other necessary requirements, including conditions as to workmanship, date of delivery, and the other points usually specified when tenders are invited. Therefore we cannot promise to give a preference on the next occasion, either to the Thames Ironworks Company or to any other firm. Any such preference, or any departure from the present practice of competitive tenders, would open the door to suspicions of favouritism and jobbery, and would be highly undesirable in the public interests. The fact that lack of work and consequent distress has existed in certain shipbuilding districts is much to be deplored. But this condition is not peculiar to London. It is not admitted that the work for the Navy in the London district has been superior to that done elsewhere—for example, in Scotland and the North of England, where the recent orders have been placed with thoroughly competent firms. Nor do we admit that the Thames Company can build a battleship 20 per cent. cheaper than it can be built in a Government yard. It is not true that in order to build the dockyard battleships the men will have to work night and day. Overtime is being kept within very reasonable bounds, and is only resorted to temporarily in cases of necessity."

*The fair wages clause.*—The Secretary to the Admiralty informed the House that the Steel Company of Newton are executing some work for the Admiralty, some of this being under a sub-contract with Messrs. J. and G. Thomson, of Glasgow. A complaint as to the wages which they pay under that sub-contract has been lately received through the Secretary for Scotland from the Associated Iron Dressers of Scotland, and was under consideration at the Admiralty.

*The atmosphere of the Underground Railway.*—A good deal has been said of late about the condition of the atmosphere in the Underground Railway tunnels. "Shall London choke?" is a question that a good many have been asking since the hot weather began. It seems that Sir Benjamin Baker has reported to the Metropolitan Company, but the latter has informed the Board of Trade that the report is of a private character. Nothing is said about any prospective attempt to improve matters.

*Rolling ships and bilge keels.*—Mr. T. G. Bowles asked whether, on a recent passage from Stornoway to Greenock, with a calm sea and heavy swell, her Majesty's ship Empress of India rolled 28 deg. and her Majesty's ship Royal Sovereign 33 deg., while her Majesty's ship Repulse only rolled 11 deg.; and whether the Repulse was the only vessel fitted with bilge keels. Sir U. Kay-Shuttleworth replied that after the experience gained some months ago of the rolling of the Royal Sovereign and other ships of her type, the Admiralty decided to fit the Repulse with bilge keels. The recent rolling of the Empress of India and Royal Sovereign has been nearly what the hon. member states, while the Repulse rolled only 11 deg. or so. Arrangements were made a few days ago to fit bilge keels as in the Repulse to other ships of the Royal Sovereign class. The existing docks can be used by the vessels thus fitted with bilge keels. We are glad to hear this, for if we remember rightly not many months ago Sir Ughtred was of opinion that there were only two docks of sufficient size.

*An alleged unsafe railway.*—In reply to Dr. Kenny, Mr. Bryce said that the Board of Trade were not aware that a feeling of uneasiness existed among those who use the Dublin, Wicklow, and Wexford Railway between Shanganagh and Bray. The Board had no power to compel the company to divert their line, but if representations disclosing a dangerous state of things are made to the Board, he would at once direct an inspecting officer to visit the locality and report.

## THE TOWER BRIDGE.

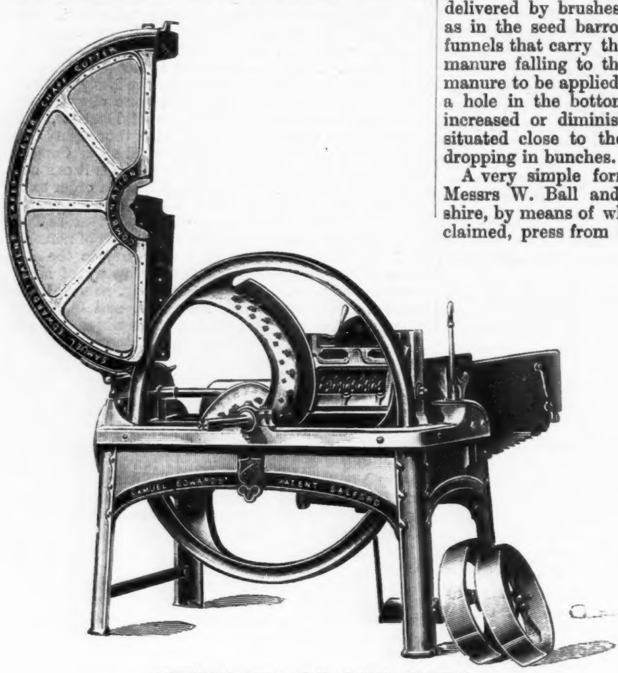
THE Tower Bridge was opened by the Prince of Wales on Saturday, the 30th of June, with much success and a great deal of well-managed pageantry. Some little time must elapse, however, before the bridge is brought into general use, as the pavilions used at the opening ceremony have to be cleared away. Numerous honours have been conferred. The Lord Mayor, Sir George Robert Tyler, becomes a Baronet; Mr. John Wolfe Barry a C.B. We believe that he was offered and refused knighthood. We have so recently and so fully described the bridge that nothing remains to be said, save to express our congratulations on the successful termination of this great work.

NAVAL ENGINEER APPOINTMENTS.—The following appointment have been made at the Admiralty:—Chief Engineer Frederick J. Flood, to the Onyx. Staff Engineer Thomas Rule, to the Bonaventure. Engineers—Henry Toop, to the Bonaventure; George H. Morris, to the Raven; Henry E. Tregenna, to the Barrosa; Charles G. Taylor, to the St. George; and John A. Murray, to the Sheldrake. Assistant Engineers—Arthur P. S. Spencer, to the Gibraltar; George S. Holgate, to the Hood; Mark Rundle and Hugh H. Ricketts (probationary), to the Bonaventure; and Henry F. Danes, to the Sheldrake. Assistant Engineers to H.M.S. Pembroke—James Maxwell, F. Magrath, W. J. Steil, Charles G. Ware, John Thomson, J. Murphy, G. H. Jeffery, E. E. Pethick, G. W. Wooldridge, and Thomas W. Richards. The following to the Victory—C. H. Harding, W. Stokes, H. F. Smith, E. P. Soper, H. T. Canning, I. E. S. Roberts, W. M. M'Donald, B. C. Minhinnick, J. J. Shirvell, and A. E. J. Murray. The following to the Vivid—J. T. C. Butland, E. Stocker, J. Kelly, G. Robertson, G. H. Page, W. B. Hall, F. G. Charlton, P. Stocker, and John H. Hare.

## THE ROYAL AGRICULTURAL SOCIETY'S SHOW.

MESSRS. J. L. LARKWORTHY AND CO., Lowesmoor Ironworks, Worcester, had on view at their stand a new implement called the "Eckley" wagon and cart hoist, which is adapted for many purposes, but particularly for farmers' use during hay making and harvest operations. It consists of a strong oak frame having a vertically movable platform, on which the cart or wagon may be drawn. The movable platform is supported by screwed brackets on four vertical screwed rods, which revolve upon ball bearings. By means of a horizontal rod and bevel gearing placed along one side of the machine rotary movement may be communicated to two of the vertical rods, and hence by chain wheels and chains to the two opposite rods, so that the platform can be raised or lowered. The horizontal first motion shaft may be provided with one or more cranks for hand driving, according to the size of the machine.

Mr. Robert Maynard, of Whittlesford Works, Cambridge, had on view a portable combined chaff cutter, fitted with a new exhaust cavings elevator, which is designed to obviate a defect prevalent in some other elevators, in which stones or other hard substances which have once passed through the feed-box are continually carried back there again, thereby damaging the knives considerably. The new elevator is operated by an exhaust, and the cavings are drawn up and deposited in the feed-box, while all the hard substances are left behind and allowed to fall to the ground. By means of this elevator, the cavings, as they are sifted from the chaff, are delivered upon and mixed with the feed as it passes into the feed-box, and so are re-cut, nothing being left behind when the chaff cutting is finished.



CROWLEY AND CO.'S CHAFF CUTTER

Messrs. Nalder and Nalder, Wantage, showed two finishing thrashing machines, and a barley dressing and grading machine.

Messrs. Woods and Co., of Suffolk Ironworks, Stowmarket, exhibited a new type of stone picking machine which is worthy of more than a passing notice. It is claimed by the patentees that not only does this machine gather all the large stones from the land, but when used upon young layers, summerlands, &c., it is a certain destroyer of the poppy and other seedling weeds, and where not too thick it is a most valuable implement as a spear grass or couch collector. The machine is mounted upon two wheels, and can be drawn by one horse. The collecting rakes are formed by rows of steel teeth and attached to three endless chains, each working on three centres, the latter being arranged so that each rake runs parallel to the earth for a certain distance, at the same time raking it, and as it rises from the earth the stones are held in the bend of the teeth. As each rake comes in contact with the earth before the previous one rises, the whole surface of the land is acted upon. The stones are carried over the top and delivered at the rear of the machine into a cradle receiver or bags. The arrangement for lifting the bags is very simple, being worked by levers, and a lad can easily take the sacks off and replace them as they become filled. The machine is very strong, simple in construction, and not liable to get out of order.

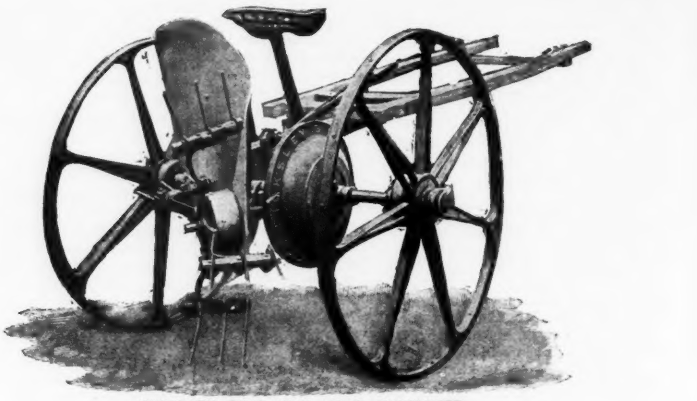
The engraving above represents a new chaff cutter, the invention of Mr. Samuel Edwards, which was exhibited on the stand of Messrs. John Crowley and Co., Sheffield, and in which there are one or two novel features. In the first place, the teeth of the feed rollers by which the material is fed to the cutting knives are arranged obliquely round the peripheries, an arrangement which is said to prevent vibration, and ensure a firmer grip upon the material. The pressure plate is made to swivel upon the shaft, and its angle of resistance is regulated by a set screw passing through the top cross bar of the mouth. By this means the said angle can be adjusted while the machine is in motion. A new feature in the swivel mouth is the absence of any fixed or projecting dead-plate inside the mouthpiece. The point of the bearing surface is inside the slots between the mouthplate and the side cheeks, thus allowing the feed to pass freely to the knives without any obstruction, and at the same time giving all the advantages of an adjustable mouthpiece. A safety lever is provided on each side in such a position as to enable the machine to be stopped or reversed, while one lever also regulates the length of cut. These levers cannot be moved in the wrong direction, when it is desired to stop or reverse the machine; while in case of accident, their disposition is such that the attendant can scarcely fail to move one of them over. A travelling feed web is fitted in the bottom of the straw box, and carries the material upon it towards the rollers, so that there is little probability of the feeder's hands becoming drawn in between the rollers. Behind the top pressure plate is placed a wooden friction roller, which only turns by the material passing over it. This is provided to prevent the attendant's hands getting too near the toothed rollers. The front of the pressure plate is open, to allow anything which might pass through the tooth plate to pass away without doing any injury to the machine. Protecting covers are used throughout the machines, so that only the driving pulleys are exposed. The cover for the fly-wheel is hinged on to the frame in a very simple manner, which allows full scope for sharpening the knives, and it can be very easily removed.

Mr. T. H. Chandler, of Rowde, Devizes, exhibited a new combined drill for seed and manure which differs from other appliances of this description in the construction of the shares which make the furrows for the reception of the seed. They are secured to the coulter by a clip and set screw, and are arranged so that any depth of furrow can be cut. The seed in the corn drill is delivered by brushes through copper plates with holes, as in the seed barrow, with dry or liquid manure into funnels that carry them into the furrows, both seed and manure falling to the earth together. The quantity of manure to be applied is regulated by a slide passing over a hole in the bottom of the box, whereby the hole is increased or diminished as required. The seed-box is situated close to the ground, and so ensures the seed dropping in bunches.

A very simple form of hay press was exhibited by Messrs W. Ball and Son, of Rothwell, Northamptonshire, by means of which two men and a boy can, it is claimed, press from 4½ to 5 tons of hay per diem. The machine is adjustable for making different sizes of trusses, and is so constructed that no needle is required for threading the string or wire round them, while the total weight of the appliance is only about one and three-quarter tons. Another new appliance shown was the "Pioneer" potato picker, which can be attached to a digger for collecting the potatoes in bags or baskets carried upon the machine. It is questionable, however, whether much saving in labour would result from the addition of this appliance to diggers, as it would of necessity also collect large stones which come in the way of the machine, and which would afterwards have to be abstracted from the bags or baskets by hand. The Halladay windmill was shown by Messrs. A. Williams and Co., Great Eastern-street, London, together with a complete set of artesian well-boring plant. These wind motors are becoming extensively adopted for raising sewage and for driving farm machinery in addition to ordinary pumping.

In flour milling machinery an exhibit of considerable interest is that of Mr. Alfred R. Tattersall, of Willesden, N.W., who shows an entirely new roller mill which will greatly economise floor space. This apparatus is designed to treat English wheats, and although not of itself a complete mill, manipulates the material by a graduated system of fluted rolls and sieves, so as to separate the bran and render it ready for sale, and make the kernel of the wheat ready for being reduced to flour by the millstones which already exist. The flour thus obtained is of high quality. Messrs. E. R. and F. Turner, of St. Peter's and Grey Friars Works, Ipswich, in point of variety have a stand which is worthy of more than a passing notice. Besides a lavish display of roller mills, various types of dressing machines for the new roller flour milling process, fixed and portable steam engines, this firm have in operation a new scalper.

Messrs. Picksley, Sims, and Co., Leigh, Lancashire, amongst their interesting group of exhibits, had one machine which was catalogued as new—their new "Palatine" haymaker, which is a simple machine designed with the object of more efficiently turning the swath or swathes and lightening the crop, while injuring as little as possible the seeds. It is a narrow machine, as will be observed from the accompanying engraving, and will take one swath only of a mowing-machine, having a cut of 4ft. 8in. The rotating set of forks are placed on an axis arranged at a suitable angle to the main axle, and driven therefrom by bevel gearing, and strike the butt end of the crop, thereby effectually turning it to the one side clear of the track, and exposing the latter to the atmosphere until the succeeding round, when the next swath is distributed over it. The machine is automatically thrown into gear when in the position for work, while when the driver, by means of a side lever, tilts the machine so that it can pass over the turned crop, or when travelling upon the road, the machine is simultaneously thrown out of gear. The tines, as will be observed, are coiled around the arms to prevent injury by coming in contact with hard materials; and the rotating forks being so near the axis, the narrow machine is rendered especially suitable for ridge and furrow, or upon rough and hilly ground. In view of the Darlington trials, and owing to the novelty in the construction of this machine, the stewards of the Royal Agricultural Society have intimated to Messrs. Picksley, Sims, and Co. that this machine may be again exhibited next year as a "new implement."



PICKSLEY SIMS AND CO.'S HAYMAKER

Messrs. Thomas Robinson and Son, Rochdale, Mr. Thomas Corbett, of Shrewsbury, Mr. A. C. Bamlett, of Thirsk, and Messrs. Howard, of Bedford, all had extensive exhibits of "standard" types of machines. Messrs. Greenwood and Batley, Albion Works, Leeds, exhibited an "Excel" pneumatic hammer; Messrs. Hawksley, Wild, and Co., Sheffield, besides a large high-pressure Lancashire boiler, showed some interesting hydraulic flanging work. The Weardale Iron Company also exhibited some beautiful examples of the same class of work.

## HYDRAULIC POWER SUPPLY FOR GLASGOW.

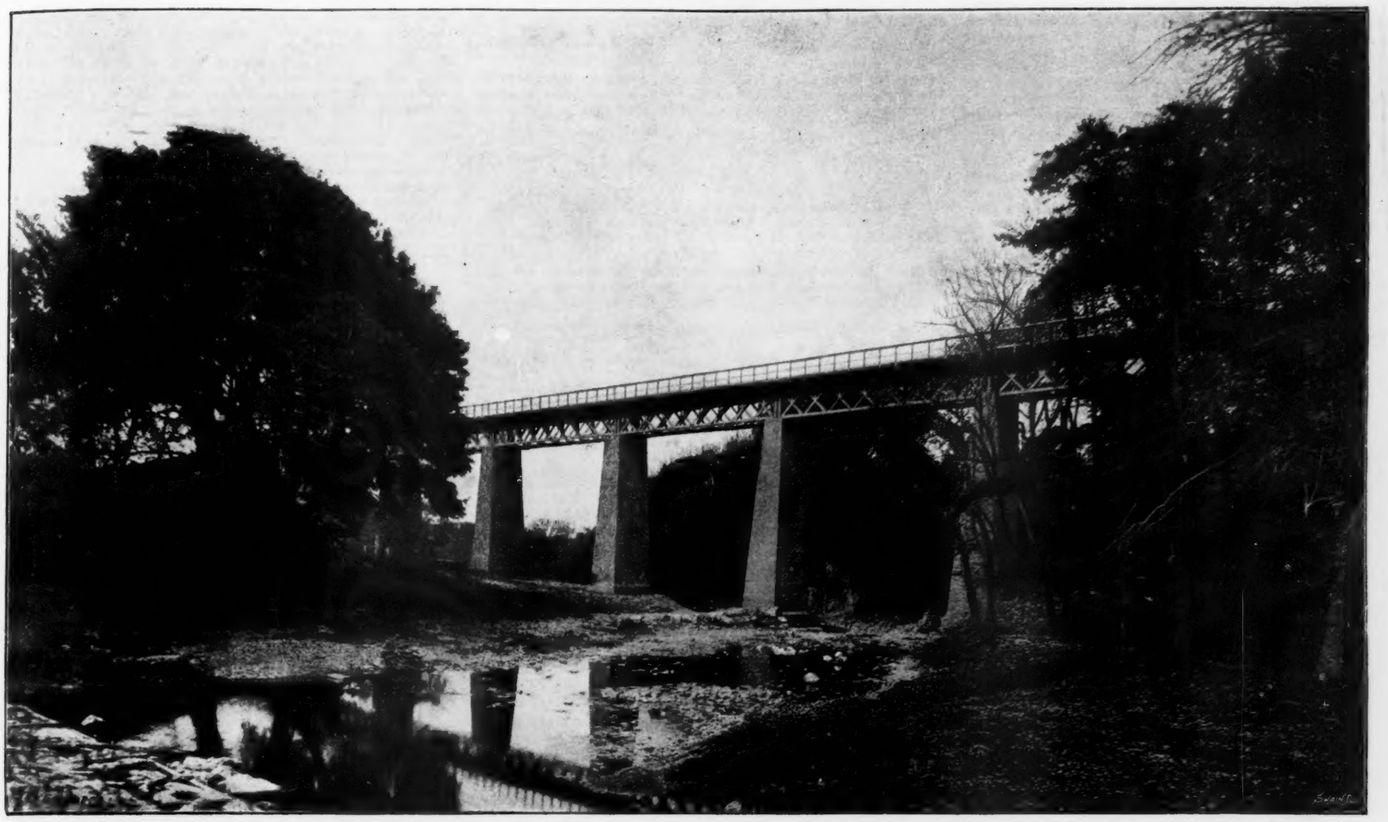
THE advantages of a high-pressure water supply for motive purposes in large towns have been for a long period so well understood, that it is a matter for some surprise that Glasgow is only now preparing to give the business community the option of using this safe and cleanly method of power transmission. About a couple of years ago Sir William Arrol and a number of other gentlemen formed a company for the public supply of hydraulic power. This involved the right to open the streets for the purpose of laying pipes and making connections, the Corporation regarding it as inadvisable that any second body should have such power, and moreover looking upon the scheme as to some extent interfering with their monopoly of the city's water supply, applied for and obtained Parliamentary powers for the supply of high-pressure water for general power purposes. The undertaking was arranged to be worked under the direct control of the Water Trust, of which Mr. James M. Gale is the well-known engineer. The general arrangement was entrusted to Messrs. Ellington and Woodall, of Westminster, and rather more than a year ago a piece of land belonging to the Corporation, at the corner of High-street and Rotten-row, was selected as a site for the power-station, where operations have since been pushed vigorously forward. The engine and boiler houses are now in an advanced stage of construction. They are of undressed ashlar, and designed externally to harmonise with the surroundings, which have been vastly improved within recent years under the operations of the City Improvement Trust. The chimney—always, unfortunately, the most prominent feature of such stations—will be 155ft. high, with a square masonry base carried up for 34ft. above the ground-line, the upper part being octagonal, and of brick with stone coigns, surmounted by an ornamental stone coping.

The mechanical arrangements of the station follow pretty closely the lines laid down at London, Manchester, and other places; but a higher working pressure, viz., 1120 lb. per square inch, has been decided upon. The steam required for the pumping engines will be derived from four steel boilers of the Lancashire type, made by Messrs. Inglis and Hossack, of Airdrie, and they are all in position. They are each 30ft. long and 7ft. in diameter, with flues 2ft. 9in. in diameter. They have been tested at the makers' works to a hydraulic pressure of 250 lb., and will be subjected to a further hydraulic test in position of 200 lb., and, finally, with a steam pressure of 160 lb. per square inch, the ordinary working pressure being 150 lb. Firing will be performed by the aid of Vickers' mechanical stokers, and the feed-water will be heated by a Green's economiser.

The pumping engines, three in number, will be inverted direct-acting triple-expansion engines, with one high-pressure cylinder, one intermediate, and one low-pressure cylinder of 15in., 19in., and 36in. diameter respectively, the stroke being 2ft. The pumps are single-acting, with plungers 4¼in. diameter attached directly to the steam piston-rods. The engines have fly-wheels 7ft. in diameter, weighing about two tons each. Each set of pumps is to be capable of delivering 230 gallons of water per minute against an accumulator pressure of 1120 lb. per square inch with a steam pressure of 120 lb., and a piston speed of 240ft. per minute. The accumulator ram will be 4ft. in diameter, the weight case, of wrought iron, being about 11ft. in diameter, and loaded to give the required pressure of 1120 lb. per square inch. All the pumping machinery is being supplied to the drawings

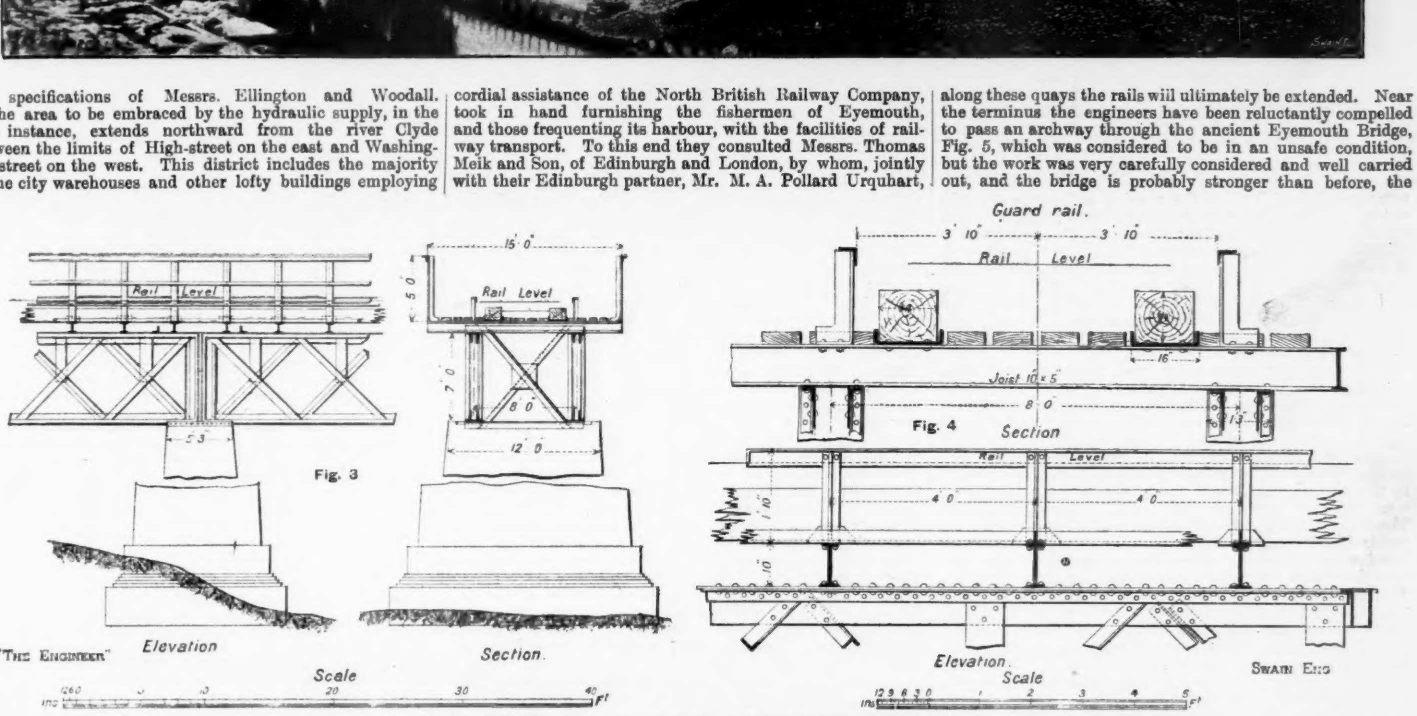
# THE EYEMOUTH RAILWAY—VIADUCT NEAR EYEMOUTH

MESSRS. THOMAS MEIK AND SONS, MM. INST. C.E., ENGINEERS



and specifications of Messrs. Ellington and Woodall.

The area to be embraced by the hydraulic supply, in the first instance, extends northward from the river Clyde between the limits of High-street on the east and Washington-street on the west. This district includes the majority of the city warehouses and other lofty buildings employing elevators or lifts of various kinds in great numbers. These are at present operated by low-pressure water obtained from the street mains, or from tanks to which it is pumped by gas engines, enabling the water to be used over and over again; but the Corporation expect that the high-pressure water will be generally adopted in preference to such expedients, and, moreover, that it will be largely used as a motive power for light machinery. All the streets in the district indicated will be intersected by the high-pressure supply pipes varying in diameter from 7in. down to 2in., the valve fittings, &c., being supplied by the Glenfield Company, Kilmarnock. The estimated cost of the whole installation is between £45,000 and £50,000, and everything is expected to be in full working order in about nine months.

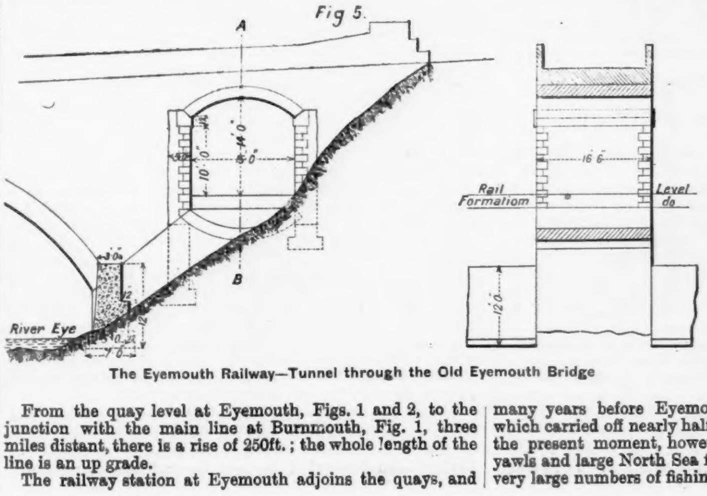


THE EYEMOUTH RAILWAY—VIADUCT NEAR EYEMOUTH—DETAILS

## THE EYEMOUTH RAILWAY.

AROUND the coast of Great Britain, and especially on the Scotch and Irish coasts, are numbers of fishery harbours giving fair accommodation so far as shelter, &c., is concerned to the fishermen who frequent them. Many of these harbours are, however, entirely without railway communication with the centres of population, and the fish having been landed have to be carted long distances inland, which wastes both time and money and produces great waste of fish, and in the event of extra large catches, as the means of transport are entirely inadequate to meet more than the carriage of a very few tons, the ultimate fate of any fish beyond this amount is to be tipped in heaps as manure!

This was very much the state of things at Eyemouth in Berwickshire, until some five years since a little company was formed, consisting of landowners and others interested in the district and harbour, and this company, with the cordial assistance of the North British Railway Company, took in hand furnishing the fishermen of Eyemouth, and those frequenting its harbour, with the facilities of railway transport. To this end they consulted Messrs. Thomas Meik and Son, of Edinburgh and London, by whom, jointly with their Edinburgh partner, Mr. M. A. Pollard Urquhart, various important works were carried out, having for their object the enlargement and improvement of the harbour and the construction of some miles of difficult railway, the contractors for the railway being Messrs. Beattie and Son, of Edinburgh.



The Eyemouth Railway—Tunnel through the Old Eyemouth Bridge

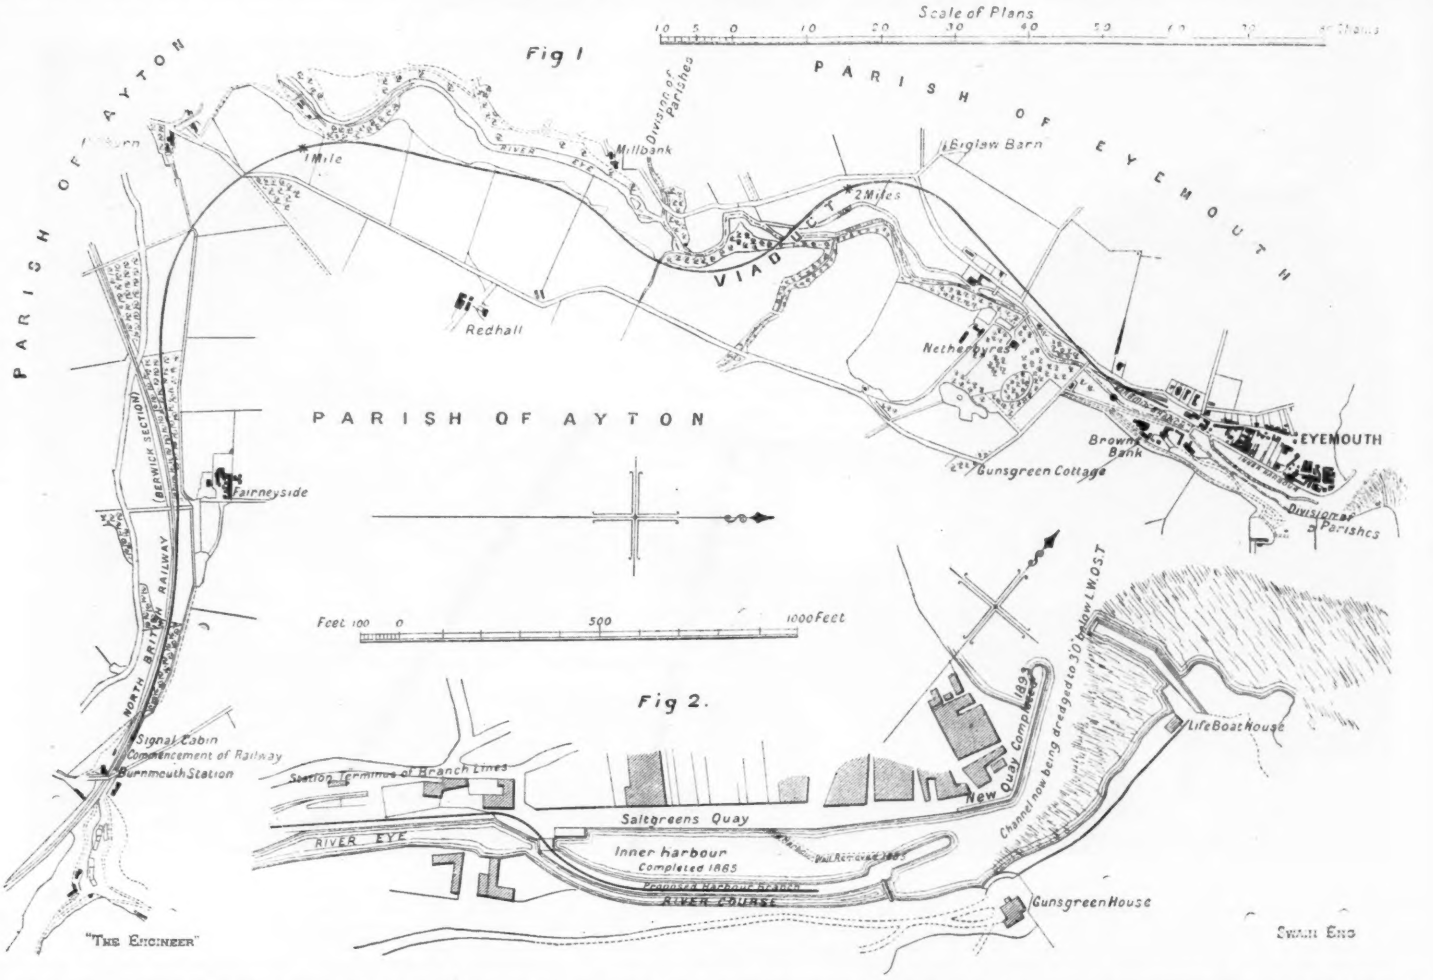
From the quay level at Eyemouth, Figs. 1 and 2, to the junction with the main line at Burnmouth, Fig. 1, three miles distant, there is a rise of 250ft.; the whole length of the line is an up grade.

The railway station at Eyemouth adjoins the quays, and along these quays the rails will ultimately be extended. Near the terminus the engineers have been reluctantly compelled to pass an archway through the ancient Eyemouth Bridge, Fig. 5, which was considered to be in an unsafe condition, but the work was very carefully considered and well carried out, and the bridge is probably stronger than before, the archway for the railway having an inverted arch sprung under the line to give additional stability.

The gradient on leaving Eyemouth Station is severe, 1 in 50, the railway keeping to the north bank of the river, which it eventually crosses at a distance of one mile from the terminus by means of a six-span viaduct, which we illustrate, Figs. 3 and 4. The viaduct is of the lattice girder type, the piers being concrete and brick. Shortly after leaving the viaduct the train enters a 50ft. cutting in hard rock. Away to the north the line passes under Hill Burn Bridge and enters the open country near Ayton Castle. Close at hand is Burnmouth Station, whence fish is despatched to all parts of the kingdom direct, even as far south as Brighton.

It will be remembered that Eyemouth is the port whence in October, 1881, sailed some fifty large fishing boats, each carrying eight hands, all of whom were lost during a great gale which occurred towards the end of the month. It was many years before Eyemouth recovered from this blow, which carried off nearly half her fishing tonnage and men. At the present moment, however, there are some one hundred yawls and large North Sea fishing boats registered there, and very large numbers of fishing vessels belonging to other ports

# THE EYEMOUTH RAILWAY—MAP OF LINE AND EYEMOUTH HARBOUR



now land their fish since the opening of the railway. The railway, although only three miles in length, contains many difficult works, and has been completed at a total cost of £21,000. The harbour improvements are now in progress; it is being deepened, and new quays are being erected, the necessary capital being obtained through the Public Works Loan Board. The railway is already a paying concern, and when the present works on the harbour are completed, there is no doubt that the capital expended on them will also bring good returns.

The Eyemouth harbour works were begun in 1883, when the Public Works Loan Board granted a sum of £25,000 for the enlargement of the old harbour—shown on dotted lines Fig. 2—these works were completed at the end of 1885. In 1891 a further sum of £10,000 was obtained in the same manner for building new quays and deepening the entrance channel; these works are now nearly completed, and already, by the increased facilities to the fishing industry, are having a marked effect on the prosperity of the town of Eyemouth. The harbour works, like the railway, are being carried out under Mr. Urquhart, of Messrs. Thos. Meik and Sons, of London and Edinburgh, whilst the contract for the harbour is in the hands of Messrs. George Lawson, of Rutherglen. It is greatly to be wished that the investing public would more readily turn their attention to works of this character, which not only give a direct return for the money invested, but which tend to increase the welfare and prosperity of the community at large by developing sources of industry hitherto suffering for want of means of communication with the large centres of population.

If people were half as ready to develope industries of this kind through responsible engineers as they now are, aided by non-technical company promoters and inside and outside brokers, to float rash speculations headed by those retired from all sorts of official positions, we should hear less of total loss of fortune on the part of investors, and nothing of the distress and poverty of the outlying fishing districts in remote parts of our coasts. The bountiful harvest of the sea would be made available to a fuller extent than at present as food for our population, a food, moreover, which unlike so large a proportion of the meat and cereals consumed in this country, we can procure for ourselves without sending money out of the country.

## THE CONGO RAILWAY.

THE views which we publish on page 12 of the Congo Railway, now in course of construction, should be of special interest at the present moment, when that State has so suddenly become the absorbing topic of European politicians. On the other hand, the commercial importance of the line in the future cannot be over-estimated. However, up to the present, in spite of some five years of work, only the first section of the line—Matadi to Kengé—has been finished, owing to climate obstacles and the great engineering difficulties which have had to be overcome. Money, too, has not been over plentiful.

On leaving Matadi, in the Congo Basin, and destined to become the greatest emporium on the West African coast, the train, running past the Belgian and Portuguese factories, issues by the Pass of the Pintades on the Leopold ravine spanned by a bridge 20 metres in length, and presently the bank of the Congo is reached, where a fine panorama comes into view. For some 6 kilometres the line is flanked by thick forests, a height of 60 metres being attained. The scenery up to the conflux of the Congo and the M'pozo is described as very grand, the great river forming several splendid falls. The engineering difficulties as far as the bridge over the Mpozo have been very great, the track having been cut through rock of the hardest nature, and laid through ravines entangled with primeval creepers and forest vegetation. The bridge across the M'pozo is of iron, 60 metres in length, and was constructed by the late M. Glaseneer. The line then runs on the right bank of the river. Presently, at a distance from Matadi of 10 kilometres, the magnificent Palaballa mountain comes into view, the elevation being now 95 metres. Here the locomotive is replenished with water. The track next runs through massive forests up to the village and mission station of Palaballa, situated at a height of 280 metres, crossing the forbidding-looking Ravine du Diable. The line runs on the left of the ravine, crossing by turns five bridges of 40, 25, 20, and 10 metres in length, thrown over ravines variously named. The track still rises some 100 to 150 metres above the Ravine du Diable until Palaballa Station is entered. This is the grandest and most interesting portion of the journey. Hence to Kengé four rivers are crossed, spanned by handsome iron bridges respectively 20, 30, 70, and 60 metres in length, but there are no engineering difficulties at all resembling those encountered between the Congo and the M'pozo. The country is more level and open, palm and banana groves being also passed. The track now descends a little, crosses the river Kimueza, thereupon the train presently runs into the Kengé Station, at an elevation of 260 metres, and 40 kilometres distant from Matadi. The run has occupied one hour and a-half, the average speed having been 17 kilometres, or 10 5 miles an hour. At Matadi a long station of corrugated iron has been constructed, and workshops, depôts, &c., with a huge hotel, also of iron. On the section of 40 kilometres described there are in all some 200 aqueducts, cuttings, &c., and 26 bridges, varying in length from 5 metres to 70 metres. The longest, 60 metres and 70 metres respectively, are found at the beginning and the end of the line. The progress of the railway is now being actively continued inland, and with more dispatch, the engineering difficulties being lessened. The railway company has just taken up a loan of 6,000,000f., wherewith to continue the work. From the last report issued by the company it appears that the total expenditure has been 18,360,272f., divided as follows:—Cost of constitution, 2,049,290f.; registration, 390,919f.; fixtures, &c., 1,255,242f.; steamers and armaments, 208,289f.; rolling stock, 792,263f.; interest on capital, &c., 2,228,135f.; service of construction, 11,436,132f. The amount at disposal is about 5,000,000f. The track has now been completed for a distance of about 60 kilometres, and the terracing effected for about another 10 kilometres. The total estimated length of the entire line should be about 150 kilometres. Naturally the chief support of the railway will be furnished by the ivory trade; and it may therefore be of interest to mention that the exports of this valuable commodity from the Congo have increased enormously since 1885—viz., 1885, 98 tons; 1886, 106 tons; 1887, 88 tons; 1888, 120 tons; 1889, 134 tons; 1890, 184 tons; 1891, 172 tons; 1892, 204 tons. Thus in seven years the exports have been more than doubled in this young State, a fact which augurs well for the future of the railway. In 1892 in Europe the sale of ivory amounted to 575 tons, as against 546 tons in 1891, and 508 tons in 1890.

We are indebted for the photographs from which our illustrations have been reproduced to M. A. J. Wauters, director of the *Congo illustré* and the *Mouvement Géographique*, having been forwarded by him through one of our correspondents. No. 1 shows a portion of the line in Palabala district. No. 2 is the bridge over the river M'pozo. No. 3 is a view on the left bank of the river M'pozo. No. 4 is a view which illustrates the difficulties encountered in driving the line along the precipitous banks of the Congo.

WEST HIGHLAND RAILWAY.—Princess Louise, the Marchioness of Lorne, will, it is understood, perform the ceremony of opening the West Highland Railway on the 12th of July. There is still a deal of work to do in connection with the undertaking, but strenuous efforts are being put forth by the contractors to have the new line ready for traffic by the above date. The brickwork of the station at Fort William is in an advanced state, and the platforms have been formed. It is proposed, however, to erect a temporary wooden structure in the event of the permanent station not being completed by the date fixed for the opening. The permanent points and crossings are being put in, and good progress is being made with the erection of signals, signal cabins, &c. Sidings and a turning-table are at present being constructed on the site of the old military fort, the houses in which are being taken down. The railway company's ground along the foreshore at Fort William is also being fenced off from the town, and the permanent way ballasted and finished off. A great deal of dissatisfaction has been caused by the company closing with fencing several lanes leading from Fort William to the foreshore. A special meeting of the Police Commissioners of that burgh was held to consider the matter, and after discussing the various points at issue, they came to the conclusion that the present operations, including the construction of railway station platforms, signal box, and fencing between the town and embankment, were not in conformity with the plans submitted by the railway company. They agreed, therefore, to ask the Board of Trade to exercise the power conferred upon them by Clause 33 of the West Highland Railway Act, 1889, and insist upon the embankment being formed in terms of the adjusted clause and approved plan. Major Marindin went over the line from Tyndrum to Craigendoran lately, and expects to have the final inspection early in July.

THE LONDON ASSOCIATION OF FOREMEN ENGINEERS.—VISIT TO MESSRS. WILLANS AND ROBINSON'S WORKS.—On Saturday last, the 23rd inst., the members of the London Association of Foremen Engineers and Draughtsmen paid a visit to the works of Messrs. Willans and Robinson, at Thames Ditton, and were cordially received by Mr. Mark Robinson and Captain Sankey. After the members had assembled in order to be photographed by the firm's photographer, they were split up into groups, each under the charge of a member of the firm's staff, and conducted round the various departments of the works. Special features of interest, which greatly impressed the visitors, were the methods of testing the accuracy of finish of each detail of the Willans engine, and the elaborate organisation by which this accuracy is constantly maintained and checked. Each engine detail, however small, is interchangeable into any engine of its series, and its history can be traced in case of any after defect or peculiarity. The extreme accuracy obtained, and shown by various tests, was an excellent object lesson to the young and even old mechanical engineers present. As an example of this accuracy, two piles of central piston valves were placed upon a surface plate. The separate rings were 0·5in. thick, and each pile contained about thirty rings. A straight edge was placed across the top of the two piles, and, by means of strips of gauge paper one-thousandth of an inch in thickness, it was shown that the accumulated thickness error did not amount to one-thousandth of an inch. After the party had visited the whole of the departments, the ywere invited to a tea, prepared in the firm's mess-room, after which a vote of thanks was given to the firm and their staff for their kindness, and reference was made to the late Mr. Willans, and the great loss which the firm and mechanical engineering generally had suffered by his premature and much-regretted death. The party returned together down the river by steam launch as far as Putney, where they separated, all being agreed that they had spent a most agreeable and instructive afternoon.

## LETTERS TO THE EDITOR.

*(We do not hold ourselves responsible for the opinions of our correspondents.)*

### ENTROPY DIAGRAMS.

SIR,—The recent articles by Dr. Lodge on this subject will, I hope, be interesting to your readers. These entropy-temperature diagrams represent well the quantity of heat in a working cylinder, although the name has often a depressing effect on engineers. To try to popularise this interesting subject, perhaps Dr. Lodge would kindly give, with your permission, an entropy-temperature diagram, worked out from an actual indicator diagram—volumes and pressures—with a description of the operation in detail, to enable practical engineers to apply them. I could send, if wished, the requisite data, as also two indicator diagrams from the same single-cylinder steam engine and at the same cut-off, all conditions being the same, except that in one case there was steam in the jacket and in the other none. Such a pair of entropy-temperature diagrams differ considerably, and are very instructive. They show well the exchanges of heat between the metal and the steam, or, in other words, the wall action in the case of a hotter and a colder cylinder. The percentages of steam and water in the cylinder at different parts of the stroke can be read off from the diagram.

These entropy-temperature diagrams represent thermal units, quantities of heat, or pound-degrees during the stroke.

Neither here nor on the Continent do reference books give clear and practical directions how to construct such diagrams with saturated or superheated steam, gas or oil motors. In a steam cylinder, while open to the boiler, a closed cycle is not carried out. Could not an entropy-temperature diagram be given for a steam, gas, and oil motor by those who understand this question better than **BRYAN DONKIN.**

Bermondsey, July 3rd.

### CARNOT AND MODERN HEAT.

SIR,—At last Dr. Lodge has taken notice of my acceptance of his challenge, but virtually avoids the contest. He has not been able to find any flaw in my argument, and has not the generosity to say so, but resorts to what I call "Mathematical Billingsgate" to cover his lack of logic. I shall, therefore, demolish my own argument, and then challenge Dr. Lodge to show—if it be so evident as he says it is—that, given that the specific heat of air, volume constant, is the same at all temperatures, the scale of the constant volume air thermometer is the same as Thomson's absolute scale. The flaw in the argument of my letter of May 11th—which I discovered immediately after its publication—is that although N—the specific heat of air of constant volume—is constant when the scale used is that of the constant volume air thermometer, it is not necessarily constant when the absolute scale is used. Hence my letter merely proves that the scale of the constant volume air thermometer does not differ from itself.

A similar flaw vitiates my proof, in Chapter XI. of my treatise, that "the scale of the constant pressure air thermometer is the same as the absolute scale." Having thus demolished my own arguments, I now formally challenge Dr. Lodge to do what I appeared to do in my letter, and which he says can be done quite easily, without "mathematical fireworks," from the given data. But I limit him to the use of ordinary logic and mathematics—*i.e.*, he must not use "oracular demonstration."

Dr. Lodge says he possesses my treatise on thermodynamics, but he has up till now neglected the common civility of acknowledging the receipt of a conplimentary copy from the author. He is very severe on some very long terms I have tried to introduce, and which, in spite of their length, are good. He neglects to say that I use, as an alternative in the same chapter, the nomenclature he ascribes approvingly to Mr. Macfarlane Gray. Dr. Lodge must have been very much put out by my letter when he introduced such weak remarks about this chapter, which is not immediately relevant to the subject under discussion. With regard to his objection to equation (24)*, it is equivalent to a clodhopper's objection to an algebraic solution of an arithmetical problem. Certainly the objection is weighty if the solution of a special example of the problem is all that is aimed at.

I admit, however, that I have in my treatise made the same mistake as Rankine made in his treatises. That is, I have first obtained the most general expressions of the laws, and from these have deduced all the particular forms. But I thought I was writing for advanced students, to whom this mode of treatment is usually more acceptable than the other, which is more suitable for beginners.

I take this opportunity of apologising to Mr. Donaldson for not answering his letters, but he will see now that I could not well do so without giving myself away, as the saying is. The chief remark I would make in reply to him is, that two things, very different in kind, may be *numerically* equal. For example:—

Force = mass × acceleration.
= rate of change of momentum.

This is a very valuable equation which follows immediately from Newton's Second Law of Motion. Perhaps I should, in quoting the formula I started with, have explained the meanings of the letters used. I do so now.

N = specific heat of air whose volume remains constant.
M = heat absorbed, per unit increase of volume, by a unit mass of air, whose temperature remains constant while it is expanding.

I need not explain further, as I can easily see that Mr. Donaldson is not so ignorant of mathematics as he professes to be.

Anderson's College Medical School, Professor of Physics.
Glasgow, June 30th.

### THE KINETIC THEORY OF GASES: VALUE OF $\beta$ FOR VAPOURS.

SIR,—In the calculation given in my last letter—page 542—for the value of $\beta$ for steam, the quantity of heat energy in water at the temperature of melting ice was not taken into account. This quantity could be found if the absolute zero of temperature and the mean specific heat of ice between that and the zero of the Centigrade thermometer were known. Now, Regnault found the mean specific heat of ice between − 20 deg. C. and 0 deg. C. to be 0·504; and between − 78 deg. and 0 deg. to be 0·474—Everett's "C. G. S. System of Units," page 107. If the absolute zero of temperature is − 273 deg., and if the mean specific heat of ice continues to decrease at the same rate as above indicated, then its mean value between − 273 deg. and 0 deg. will be 0·37. But the specific heat may decrease more rapidly as the temperature falls, or the absolute zero of temperature may be lower than − 273 deg., either of which circumstances would reduce its value.

If $\bar{s}$ represent the mean specific heat of ice, and $\bar{S}$ that of water between the absolute zero − N deg. and 0 deg C., then $N\bar{s}$ will be the quantity of heat in ice, and $N\bar{S}$ the quantity in water at the temperature of melting ice. The difference between these quantities will be the latent heat of water at 0 deg. C. Hence, if L equal the latent heat at this temperature,

$$L = N(\bar{S}-\bar{s}) \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (1)$$

In the above equation the meaning of $\bar{S}$ may be interpreted thus. Supposing water could fall to − N deg. without change of physical state, its specific heat would fall also, becoming zero at the absolute zero of temperature. For we may define the specific heat of a substance at a given temperature as the heat necessary to be withdrawn from it to cause it to fall 1 deg. in temperature. Thus the specific heat of all substances will vanish at the absolute zero of temperature. $\bar{S}$ is then the mean specific heat of water between − N deg. and 0 deg. C. under the supposed conditions. Now Person found experimentally—see Miller's "Elements of Chemistry," vol. 1, page 367—that the latent heat of liquids is given by the equation

$$L = (160 + t)(S - s); \quad . \quad . \quad . \quad . \quad . \quad . \quad (2)$$

where $t$ is the temperature of fusion, S the specific heat of the liquid, and $s$ that of the solid at that temperature. In the case of water $t = 0$, and the equation becomes

$$L = 160(S - s) \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (3).$$

Combining (1) and (3) we get

$$N(\bar{S} - \bar{s}) = 160(S - s) \quad . \quad . \quad . \quad . \quad . \quad . \quad (4).$$

If we assume, as is only reasonable, that the ratio of the specific heats of water and ice remain the same at all temperatures, and that $n$ is this ratio, then in the last equation we may substitute $n\,s$ for S, and $n\,s$ for S, and it becomes

$$N\bar{s}(n-1) = 160\,s(n-1),$$
$$\text{or, } N\bar{s} = 160\,s.$$
$$\text{Similarly } N\bar{S} = 160\,S.$$

But $N\bar{S}$ is the quantity of heat in 1 lb. of water at 0 deg. C., hence 160. S is also this quantity, and since S for water at the above temperature is unity, the quantity of heat in 1 lb. of water is 160 units.

It was shown in my last letter that $\beta$ was the ratio of the total energy in steam to the energy of its latent heat. Hence steam at 100 deg. C., since its latent heat is 537, has a total energy of 637 + 160 units, or 797. Therefore, $\beta = \frac{797}{537} = 1{\cdot}484$. At 200 deg. C. the latent heat of steam being 476 5, $\beta = \frac{676{\cdot}5 + 160}{476{\cdot}5} = 1{\cdot}77$; showing an increase of about 19·6 per cent.

London, June 28th. **C. E. BASEVI.**

### THE LATENT HEAT OF STEAM.

SIR,—In your last few issues there have appeared criticisms by Mr. Donaldson of an equation given by Mr. Alexander. It appears from them that Mr. Donaldson's grievance is rather with the fact that he does not understand the notation. One can hardly believe that Mr. Donaldson is such an ardent student of thermodynamics as he professes to be if he is not familiar with the writings and notation of Lord Kelvin on the subject. Perhaps it will relieve Mr. Donaldson's mind if you will kindly insert the following method of deducing the equation—

$$J\left\{\left(\frac{dM}{dt}\right)_v - \left(\frac{dN}{dv}\right)_t\right\} = \left(\frac{dp}{dt}\right)_v.$$

The first law of thermodynamics gives us—

$$J\,dQ = dE + dW \quad . \quad . \quad . \quad . \quad . \quad . \quad (1)$$

where $dQ$ = quantity of heat received by the body; $dE$ = internal work done; $dW$ = external work done.

Now, in the mechanical theory of heat we have as characteristic equation of a body—

$$F(p\,v\,t) = 0,$$

where $p$ = pressure, $v$ = volume, $t$ = absolute temperature. F is a function determined experimentally. We may choose any two of these variables as our independent variables. Let them be $v$ and $t$. Then—

$$\left.\begin{aligned} dQ &= \frac{dQ}{dv}dv + \frac{dQ}{dt}dt \\ dE &= \frac{dE}{dv}dv + \frac{dE}{dt}dt \\ dW &= \frac{dW}{dv}dv + \frac{dW}{dt}dt \end{aligned}\right\} \quad \begin{array}{c}\text{Substitute}\\ \text{in}\\ \text{Equation (1).}\end{array}$$

We have

$$J\left\{\frac{dQ}{dv}dv + \frac{dQ}{dt}dt\right\} = \left\{\left(\frac{dE}{dv} + \frac{dW}{dv}\right)dv + \left(\frac{dE}{dt} + \frac{dW}{dt}\right)dt\right\}$$

An identity from which we conclude

$$\left.\begin{aligned} J\frac{dQ}{dv} &= \frac{dE}{dv} + \frac{dW}{dv} \\ J\frac{dQ}{dt} &= \frac{dE}{dt} + \frac{dW}{dt} \end{aligned}\right\} \quad \begin{array}{c}\text{Eliminate}\\ \frac{dE}{dv} \text{ and } \frac{dE}{dt}.\end{array}$$

$$J\left\{\left(\frac{d}{dt}\right)_v\left(\frac{dQ}{dv}\right)_t - \left(\frac{d}{dv}\right)_t\left(\frac{dQ}{dt}\right)_v\right\} =$$
$$\left(\frac{d}{dt}\right)_v\left(\frac{dW}{dv}\right)_t - \left(\frac{d}{dv}\right)_t\left(\frac{dW}{dt}\right)_v.$$

Now put $W = p\,dv$.

$$J\left\{\left(\frac{d}{dt}\right)_v\left(\frac{dQ}{dv}\right)_t - \left(\frac{d}{dv}\right)_t\left(\frac{dQ}{dt}\right)_v\right\} = \left(\frac{dp}{dt}\right)_v\left(\frac{dv}{dv}\right)_t -$$
$$\left(\frac{dp}{dv}\right)_t\left(\frac{dv}{dt}\right)_v = \left(\frac{dp}{dt}\right)_v.$$

Now $\left(\frac{dQ}{dv}\right)_t$ denotes the latent heat of dilatation. Lord Kelvin uses M for this.

$\left(\frac{dQ}{dt}\right)_v$ is the specific heat at constant volume, replace it by N.

Then our last equation becomes—

$$J\left[\left(\frac{dM}{dt}\right)_v - \left(\frac{dN}{dv}\right)_t\right] = \left(\frac{dp}{dt}\right)_v \quad . \quad . \quad . \quad . \quad . \quad (2)$$

the required equation.

Mr. Donaldson has not attacked Mr. Alexander's final result, and I think he will now see that his analysis of equation (2) is a failure. **STUDENT.**

Cardiff, June 25th.

### STEAMSHIP PROPULSION.

SIR,—Colonel Beaufoy, in his "Nautical and Hydraulic Experiments," makes use of the following definitions:—

By *head pressure* is meant the total pressure which exists against the head end, or foremost part of a body, immersed either wholly or in part in any given fluid when such body is at rest.

By *stern pressure* is meant the total pressure which exists against the stern end, or hindermost part of a body under the same conditions.

By *plus pressure* is meant the additional pressure which is sustained by the head end, or foremost part of a body moved through a fluid; which additional pressure is over and above what we have termed the head pressure, and arises from the fluid being obliged to be displaced in order to permit the moving body to pass through it.

By *minus pressure* is meant a subtraction of pressure from the stern pressure, and which subtraction is occasioned by the fluid not pressing so strongly against the stern end, or hindermost parts of a body, when such body is in motion through the fluid as when the body is at rest.

By *friction*—as relating to this subject—is meant that sort of resistance to a body moved through a fluid, which arises either from the adhesion of the particles of the fluid to the surface of the moving body, or from the roughness of the body, or from both those causes combined.

By *total resistance* is meant the sum total of the plus pressure, the minus pressure, and the friction united.

These definitions are as suitable to a steamship to-day as they were one hundred years ago, except that perhaps in the definition of friction the viscosity of the fluid would have to be taken into account.

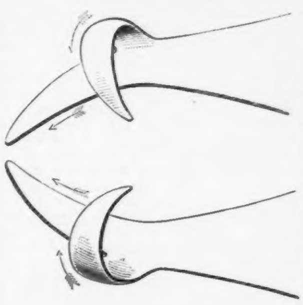
It is of course a truism to assert that if any of these resistances can be reduced in any ship, she can be made to travel faster with the same expenditure of power.

Putting aside the plus pressure and the friction, I propose to confine my remarks to the minus pressure, which, I think I may say without fear of contradiction, is *chiefly* caused in a steamship by the inertia of the water.

A little reflection will show that this minus pressure must have a limit, and that that limit will be reached when the steamship is travelling at the velocity at which water at rest will flow into a vacuum—or about 18 knots. At speeds above this the minus pressure will remain constant, and consequently the total resistance will increase in a lower ratio—compared to the velocity—than at lower speeds. This is exactly what is found to be the case in torpedo boats which have what Mr. Mansel calls a "critical speed" at about 18 knots, above which speed the resistance *actually* increases in a much lower ratio than it does at speeds below this.

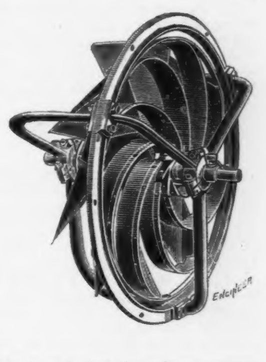
This minus pressure acts in a similar manner to the brake on the guard's van of an ordinary train, and if this "brake" can be taken off the stern of the vessel an increase of speed will be the result. Is it *possible*, however, to take this brake off? Or if not possible to take it off entirely, is it possible to reduce its resistance to the ship's advance? I think that undoubtedly it *can* be reduced very materially, and by a very simple device.

Some time ago—I forget the exact date, but that is immaterial—a whale was stranded on the shores of Great Britain, and, having been killed, its measurements were carefully taken, and calculations made of the number of horse-power which it must have exerted in travelling at a certain speed. Now, had the whale been moved by a tow line, or had it been propelled by a screw propeller, these calculations would probably have brought out a result not far removed from the truth; but the whale's tail is *not* a screw propeller, and its action does not resemble that of a screw propeller; there is an essential difference. I am afraid I am a little sceptical of some of these calculations, for I *have* seen that a savant calculated that seventeen swallows could, and did under certain circumstances, exert one horse-power whilst flying; also the power exerted by a goose whilst on the wing has been calculated variously at 10-horse power, 1-horse power, and $\frac{1}{10}$-horse power, the lowest of which even appears somewhat excessive. As M. Bertrand said, it would be "as easy to prove by calculation that birds could *not* fly—a conclusion which would rather compromise mathematics." If the action of a fish's tail be examined carefully, it will be seen that whilst what I may call one "blade" of the tail is propelling the fish, the other "blade" is forcing water centripetally towards the base of the tail, and so reducing the minus pressure — the two blades acting alternately in the manner indicated by the rough sketch.



Now, a ship travelling through the water has a considerable minus pressure at its stern, and the screw propeller causing *some* centrifugal motion of the water increases this minus pressure, instead of reducing it. If, however, supplementary or "feeding blades" be placed on the leading side of the propeller, so as to cause a *centripetal* movement of the water in front of the propeller, the minus pressure will be reduced or eliminated, according to the size of the feeding blades—in the same manner as is done by the fish—and the resistance of the ship to motion will be reduced. This, of course, will result in increased speed.

To explain my meaning better, I attach a sketch of the "Tattersall" ventilating fan, where the same principle has been adopted. It is perhaps not so apparent at first sight why this should be advantageous in a fan—which is stationary—but I see it stated that these supplementary blades increase the efficiency of the fan by 25 per cent. without necessitating any increase in the driving power.

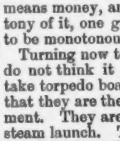


On a steamship the advantage in reducing the minus pressure will be self-evident, and whilst the feeding blades will do this when the propeller is revolving in one direction to make the ship advance, when the propeller is reversed, these supplementary blades acting centrifugally, will enormously increase the minus pressure, and so bring the ship to rest in a reduced time; in the same manner on a vessel with twin screws the power of turning the ship with the propellers alone will be increased.

St. Helena, June 12th. **R. DE VILLAMIL.**

### STRESS IN CRANE HOOKS.

SIR,—At a large quarry a crane hook recently broke while carrying about three tons. The hook is of the ordinary construction. The peculiarity, as it seems to me, of the fracture is that the hook broke right under the ring. The dotted line shows the fracture. Now I shall be much obliged if some reader will explain to me what were the stresses in this hook, and how to plot them graphically. I cannot understand why the hook broke just where it did. There is no evidence of a flaw. **QUARRYMAN.**



Inverary, July 2nd.

### ENGINEERING AS A PROFESSION.

SIR,—Your correspondent Mr. Dodd is a man with whom I should like to shake hands. I have spent about as many years at it as he has, and I can endorse all he says. Repetition work means money, and so does division of labour; but as to the monotony of it, one gets used to that. All work that I know of gets to be monotonous—it comes the easier.

Turning now to "E. C. A." He cites Messrs. Yarrow. Now, I do not think it is right to mention individual firms. But I will take torpedo boats in the mass, so to speak, and I assert plainly that they are the result of nothing but extended and costly experiment. They are neither more nor less than an outcome of the steam launch. Their history is the same as that of the Atlantic greyhound, or the modern express engine. They are the result of trial and error. Mr. Froude taught torpedo boat builders nothing, but he learned a great deal from them. I have said, and I repeat, that the great bulk of the mechanical engineering trade of this country—a trade representing a turnover of millions of pounds sterling per annum—is no more scientific than the trade in blankets and tea. Of course there are exceptions, but they have next to nothing to do with the matter being discussed.

Mr. Lightfoot's letter can be answered in a few words. He suggested superheated steam as an outcome of thermodynamic theory. I replied that superheating had been tried before thermodynamics had been heard of as such by engineers. I pointed out that the refrigerating machine was not suggested by anyone versed in thermodynamics. I said that it was a growth. I do not for an instant dispute that at the eleventh hour the chemist has come in and suggested improvements.

But I shall simplify matters with Mr. Lightfoot by offering him a challenge. If he will tell me what Hirn has done to improve the steam engine, and to what extent he has improved it, as a mathematician and a physicist, I will acknowledge that I have been all wrong. I shall admit that I have entirely failed to appreciate the value of scientific work in bettering the steam engine.

On the other hand, if Mr. Lightfoot fails, I shall expect him to admit that he has overrated the value of pure science as compared with the effect of evolution, the survival of the fittest, which has, I maintain, produced the modern steam engine, aye, and the modern refrigerator too. Why, even as regards the dynamo, one of the most recent and startling improvements has been brought out, as I am informed, by a man with little or no scientific training. May I, in conclusion, ask Mr. Lightfoot what he thinks of Edison?

DENARIUS.

July 2nd.

SIR,—Referring to my letter in your last issue, I beg to state that there is an error in the fourth line. "Experiments conducted by him" should be "Experiments conducted by Hirn." This is, of course, totally different, so I trust you will find room for this correction in your next number.

CECIL LIGHTFOOT.

7, Eastcombe Villas, Blackheath, S.E., July 1st.

July 3rd.

THE PROJECTED TOWER BRIDGE OF THE YEAR 1824.

SIR,—Now that this noble structure is completed, it is interesting to recall the particulars of the construction as it was intended to be seventy years ago, which I take from the *Mechanics' Register*. In its impression of March, 1824, it is stated that an application was to be made to Parliament for leave to erect a wrought iron bridge over the Thames from St. Catherine's to the opposite shore, the bridge to be of an elevation sufficient to admit ships to pass under it at all times.

A Captain Brown seems to have made a report thereon, for in the May number the following extract is given from his report:—"The bridge is to consist of three spans of 600ft. each and two side spans of 300ft. each. The extent of the suspended bridge, including the towers, is 2400ft., or a little more than half a mile. The road on the north side is to take its rise from Little Tower-hill, opposite to the Minories; that on the south side near Dockhead, in Bermondsey, which forms a central point to the streets leading to the great Kent and Surrey roads. The rise from its commencement on each side is formed by an easy acclivity of one foot perpendicular in 20 horizontal. The carriage way is to be 21ft. wide, and the footpaths on each side, 8ft.; the height of the bridge above high water mark, 70ft. in front of the towers, rising to 75ft. in the centre. This height will allow ships of 200 tons to pass without striking their topgallant masts, and ships of 300 and 400 tons to pass with their main topgallant masts down. The towers will be constructed of granite. Each of the bridges will be supported by sixty-four principal bars or belts of suspension, 2½in., as shown in the designs. The bolts will be 20ft. long, joined by side plates and pins of proportional strength. They will be extended from their respective points over the towers, in four rows, each over other, one foot apart, each row to consist of four lines of bolts parallel with each other. These principal lines of suspension may now be denominated chains, although differing from the common form and acceptation of the word. The joints being exactly opposite to each other, the saddles which support the perpendicular bolts rest on them and bear equally on all. The principal suspenders are so arranged that the beams are ultimately supported by a different row of chains, so that an equal strain is produced."

The foregoing plan renders the united strength of the principal suspenders certain, and Captain Brown estimates the least breaking weight of any one span 3204 tons. The total weight that could be put on the bridge he estimates at 550 tons. It will be necessary to state most unequivocally, he says, that there will be no hindrance on land or water during the erection. When the towers are finished temporary chains, fixed in half an hour, will be stretched across, and the whole by means of a temporary gangway will be put together aloft.

J. H. RAWLINS.

15, Kelvin-grove, Liverpool.

## AMERICAN ENGINEERING NEWS.

(*From our own Correspondent.*)

*Torpedo boat Ericsson, United States Navy.*—The latest addition to the "new navy" of the United States is the torpedo boat Ericsson, which was launched at Dubuque, Iowa, on the Mississippi River, in May. This is really the first torpedo boat built for the Navy, as the Cushing—or No. 1—was altered from her original design to suit her for torpedo work. The Ericsson, while larger than the Cushing, does not draw so much water. The Cushing has a length on load water-line of 138¾ft., a beam of 14ft. 10in., and a mean draught of 5¼ft., giving her a displacement of 110 tons. The new boat has a length of 150ft., a beam of 15½ft., and, with a depth of 10ft. 6in., has a normal draught amidships of 4¾ft., with a displacement of 120 tons. She has 1800 maximum horse-power, against the Cushing's 1720-horse power. The motive power, though greater than that of the Cushing, is similar. It consists of two sets of four-cylinder quadruple-expansion engines of the vertical inverted direct-acting type, operating twin screws. The cylinder diameters are 11½in., 16in., 21½in., and 30in. The stroke of all pistons is 16in. The estimate of 1800 indicated horse-power of the propelling and circulating pump engines is based on the propeller speed of 412 revolutions per minute. One water-tight compartment is sufficient for the two engines. Each of the two Thornycroft boilers is also in a water-tight compartment, the engines standing between them. The Cushing, with a required speed of 22 knots an hour, made 22·52 on her trial trip, and has done better since. The required speed of the Ericsson is 24 knots, and the builders are to receive premiums ranging from 2500 dols. to 3500 dols. for each quarter knot above the guarantee, and corresponding reductions are to be made for deficiencies. This speed requires the best possible model, engines, and boilers. It also demands strength and accurate bearings. To secure strength the transverse system of construction has been adopted. Longitudinal strength has been secured by the use of an intercostal vertical keel and broad, heavy stringer plates. The intercostal keel connects the outer keel plate firmly to the inner flat keelson. This prevents tripping of the floors and reduces the vibration caused by the engines. The frames are of steel and the plating of galvanised steel $\frac{3}{16}$in. to ¼in. thick. The conning tower is of conical form, about 6ft. diameter and 7ft. high. The interior of the boat is divided into twelve water-tight compartments by bulkheads. In the bow are the steam windlass, locker seats, torpedo store-room and crew space for the twelve men. Amidships are two fresh water tanks for distilled water, 360 gallons, boiler room, engine-room 10ft. by 20ft., and boiler room with coal bunkers on either side, lockers for signals, compass-room, and state-room for commander and engineers, next to which is the powder magazine. Aft, are the ward-room, officers' dining-room, lavatory, &c. The interior is covered with cork paint to prevent the sweating of the metal. The armament of the Ericsson consists first of a fixed torpedo tube, whose mouth, 18in. in diameter, is in the prow 2ft. above the water-line. This is fired by compressed air, controlled from the conning tower. On the deck are four one-pounder rapid-fire guns for repelling boarders. There are two turntable tubes on a training circle aft on the upper deck, just abaft the after funnel. The diameter of these is 14in. The Whitehead torpedo will be used. The turntable tubes will be discharged with powder. The torpedoes are intended to be discharged at a range of about half a mile, and the torpedo boat, travelling at twenty-seven knots, would be difficult for the enemy to hit. The complement of officers and crew will be twenty in all. The boat will be sent down the Mississippi to the gulf, and delivered to the Government at the Pensacola navy yard in Florida. It may be mentioned that torpedo boat No. 1, the Cushing, is named after Lieutenant Cushing, U.S. Navy, who during the civil war succeeded in blowing up the frigate Albemarle with a spar torpedo from an open torpedo launch, the boat being almost simultaneously smashed and sunk by a shot from the Albemarle. At the same yards at Dubuque is being built the revenue cutter William Windom, which will not be completed until next spring. Her dimensions are:—Length, 171ft.; beam, 27ft.; depth, 13½ft.; contract price, 98,000 dols. She will have a single Scotch double-ended boiler of 800-horse power, a pair of triple-expansion engines of 800-horse power, and a hull plating of ⅜in. steel. She will be placed in the service of the Treasury Department at the Baltimore station.

*Railways of Massachusetts.*—The report of the Railway Commissioners of Massachusetts for the year 1893 contains some interesting details of receipts, operating expenses, &c., as shown in the table below. The State has 2120 miles of main and branch lines, with 4151 miles of track.

| | |
|---|---|
| Number of passengers | 119,779,947 |
| Average journey per passenger | 14·56 miles |
| Number of passengers carried one mile | 1,744,388,553 |
| Average passenger fare per mile | 1·83 cents |
| Number of tons of freight | 32,995,033 |
| Average haul per ton | 73·68 miles |
| Number of tons carried one mile | 2,431,081,708 |
| Average freight rate per ton per mile | 1 39 cents |
| Passenger revenue | 50·16 per cent. |
| Freight revenue | 48·44 „ |
| Other earnings | 1·40 „ |
| Gross assets | 334,744,845 dols. |
| Gross liabilities | 320,551,031 dols. |
| Percentage of surplus to capital | 7 60 per cent. |
| Capital stock | 186,440,423 dols. |
| Net debt | 115,003,021 dols. |
| Total income | 76,391,933 dols. |
| Total expenditures | 75,163,831 dols. |
| Gross income from operation | 54,480,968 dols. |
| Operating expenses | 37,188,292 dols. |
| Percentage of expenses to income | 69·79 per cent. |
| Gross earnings per mile | 16,390 dols. |
| Cost of operation per mile | 11,438 dols. |
| Passenger train mileage | 26,041,383 |
| Freight „ „ | 19,172,518 |
| Other „ „ | 12,213,041 |
| Total „ „ | 57.426,942 |
| Earnings for total revenue train mile | 1·558 dols. |
| Cost of running trains per train mile | 0·862 „ |
| Cost of repairs per total train mile:— | |
| Roadbed | 0·100 „ |
| Bridges | 0 018 „ |
| Rails | 0·016 „ |
| Locomotives | 0 039 „ |
| Passenger cars | 0 034 „ |
| Freight cars | 0·046 „ |
| Wages per total train mile | 0 298 „ |
| Fuel per total train mile | 0·101 „ |
| Total | 0 652 „ |
| Number of employés | 48,381 |

*Railway operating statistics.*—In this column of THE ENGINEER I have already given the actual operating statistics of several American railways, which are in many ways of greater value than the assumed averages for the whole United States, which are so often used in discussions on railway rates, &c. Below I give similar statistics of the Norfolk and Western Railroad for the year ending December 31st, 1893, which railroad is an important coal and freight route, comprising 1567 miles:—

| | |
|---|---|
| Miles of railway | 1567 |
| Locomotives per mile | 0·26 |
| Passenger cars per mile | 0·17 |
| Freight, &c., cars per mile | 11·10 |
| Passenger engine mileage per day | 117·33 |
| Freight engine mileage per day | 80·16 |
| Freight car mileage per day | 33·24 |
| Average load per freight car—tons | 18·11 |

TRAWDEN SEWERAGE SCHEME.—A Local Government Board inquiry has recently been held at Trawden by Colonel Ducat, R.E., into an application by the Local Board of Trawden for a loan for works of sewerage and sewage disposal. The sewage scheme is being carried out with a view to prevent pollution of the tributaries of the Calder. Mr. William Dent, the Board's engineer, described the sewage purification system to be adopted, which is that known as the "International," consisting of precipitation by ferozone, and filtration through polarite, with tanks on the continuous flow principle. Evidence was given in support of the application, and the inquiry then terminated without any opposition.

THE NATIONAL TRACTION ENGINE OWNERS' AND USERS' ASSOCIATION.—A general meeting of the Association was held, according to the rules, at the Royal Agricultural Society's Show at Cambridge on Wednesday last. The meeting was held, by the permission of the Council of the Royal Society, in their tent. Mr. H. D. Marshall, of Gainsborough, took the chair, among those present being Mr, J. E. Ransome (President of the Agricultural Engineers' Society), Mr. T. Aveling of Rochester, Mr. Burrell of Thetford, Mr. Murrison of Aberdeen, Mr. Jesse Ellis of Maidstone, Mr. Allen of Oxford, Mr. Chittenden of West Malling, Mr. de Mattos of Dorchester, Mr. R. W. Eddison of Leeds, Mr. Willcox of London, Mr. R. Neville of Somerset, Mr. Hancock of Bristol, and Mr. H. R. Summers (the secretary). The report of the General Council on the work of the Association since its inauguration in December last was read. Mr. Murrison, of Aberdeen, spoke of the strength of the feeling being aroused in Scotland on the subject. Mr. R. Neville told how the Somerset County Council had, in response to a local deputation of engine owners, lengthened the hours during which engines could work through the country. Mr. J. E. Ransome referred to the strong opposition against railways which had now been overcome, and said that the opposition against the traction engine would be similarly overcome; and stated that he knew from practical experience that horses could be educated so as not to have the least fear of traction engines. Mr. Knight, of Farnham, spoke of the facilities given in France to steam road locomotion. Mr. Hancock, of Bristol, spoke of the difficulties under which showmen who want to take a large number of light wagons behind one engine have to put up with. Mr. Jesse Ellis, of Maidstone, spoke of the trouble and annoyance caused by having to take out a fresh licence for each county, and of the necessity of all engine owners joining the Association. Mr. Burrell proposed and Mr. Eddison seconded a hearty vote of thanks to the chairman, and the meeting concluded.

## THE IRON, COAL, AND GENERAL TRADES OF BIRMINGHAM, WOLVERHAMPTON, AND OTHER DISTRICTS.

(*From our own Correspondent.*)

THE fact that the quarterly meetings are to be held next Thursday in Birmingham, and in Wolverhampton on the previous day, tends to restrict current business within narrow limits. No one seems inclined to order in advance of those gatherings. Prices on the whole may be expected to be rather weaker than was the case in April, though doubtless the strained position of affairs in the coal trade will have a tendency to prevent as much decadence as might otherwise be observable. Staffordshire furnace coal is quoted 10s. to 11s.; best forge, 9s.; second sorts, 8s. 6d.; and ordinary 7s. Manufacturing slack ranges from 5s. down to 3s., according to quality and fineness. Inquiries made as to the course coke is likely to take show that vendors are endeavouring to keep up prices. North Staffordshire descriptions are 13s.; Yorkshire, 16s. to 18s.; Derbyshire, 16s.; and Welsh, 16s. 6d. to 18s. These are furnace sorts. Foundry coke from South Wales is quoted 18s. to 21s., and from the North-East coast, 22s. to 25s. In the manufactured iron and steel trade a fairly regular business has of late been carried on.

Cinder pigs are 37s. 6d. to 38s.; part mines 41s. to 42s., and hot blast from 55s. to 62s. 6d., according to quality. Galvanised corrugated sheets are quoted £9 15s.; and black doubles £6 10s., whilst trebles are £7 5s. An important step has this week been taken in the local iron trade. Owing to the unsuccessful attempt at a sale of the iron and steel works of the New British Iron Co., Corngreaves, to which I referred last week, notice has this week been posted to the workpeople terminating all contracts at the end of the month. The effect of this decision will be that one of the oldest of the Staffordshire iron works will cease manufacturing. It has for some time past been evident that only the sale of the works as a going concern could prevent this step, and the attempt in this direction having failed, no alternative is left but to close down the concern. The position of the firm as a marked bar house and as Government contractors for iron and steel was considerable, and its history dates back into some of the best periods of the Staffordshire iron trade. The effect of the closing of the works must be to throw out of employment a large number of both iron workers, colliers, and other classes of labour. The company employ from 1500 to 1800 workpeople, and at one time the pay roll was £2000 a week in wages.

The local steel works are profiting to some extent by the quietude in the iron trade. The basic steel works at Bilston of the Staffordshire Steel and Ingot Iron Co. are understood to have already booked large orders on next quarter's account. The new steel works of the Round Oak Iron Co., Brierley Hill, with which the Earl of Dudley is connected, are progressing satisfactorily, and are expected to be in operation in a month or two. Staffordshire steel boiler plates of basic quality are quoted at date £6 5s., tees and channels £5 10s.; machine shafting bars—round—from 1¼in. up to 6in., £6; bridge plates, £5 10s., and angles £5 5s. In comparison with these prices may be placed the figures at which some of the North of England steelmakers are offering what they declare to be Siemens-Martin steel delivered into this district. The figures are:—Billets, £4 5s.; bridge plates, £5 12s. 6d. to £5 15s.; plates to stand Indian States Railway tests, £6; and boiler plates £6 5s. The Lilleshall Steel Co., Shropshire, quote steel wire rods, delivered into the Birmingham district, £5 15s., and plating bars, £5 2s. 6d. to £5 5s. Leeds steel joists are quoted, delivered Birmingham, £5 10s.; channels, £5 15s., and bars, flat, £5 5s. per ton.

Much satisfaction was expressed on 'Change in Birmingham on Thursday at the information of the passing of the American Tariff Bill. Reports from the other side of the Atlantic have for so long a time been of a contradictory nature regarding the chances of the measure, that the intelligence of its success in the Senate comes as a relief, and improved anticipations are indulged of the future of trade. Private advices received by certain leading houses in this district announce that when trade revival commences in America, and costs of material and manufacture begin to go up there, British iron and steel makers will, under the new duties, now be able to send in material and command American orders. The new tariff entirely removes the duty on baling hoops, of which 40,000 tons are annually consumed for the American cotton crop. The probability is that British ironmasters will now secure more of this business than ever before.

A very fair account is given by the bridge builders of the current demand, steel structures being well called for for the colonies and some of the foreign markets. A moderate extent of business is reported in the chain and anchor trades, but there is continued quiet in some other departments of the heavy hardware industries. The vice and anvil makers report rather more business for the home trade, but the continental and colonial demand is very dull. Steam tube makers are more favourably situated, and here and there good contracts are in hand among the engineers.

A week or two ago I announced that the result of the appeals which have recently been made by manufacturers in Wolverhampton to the Union Assessment Committee against the increased rating of their machinery and other properties, would very probably be that certain of the cases would be carried to quarter sessions. It is now definitely made known that several of the leading firms and other property owners have resolved upon taking this course, and unless the Union authorities consent to further reductions, the appeals are certain to go into court.

## NOTES FROM LANCASHIRE.

(*From our own Correspondent.*)

*Manchester.*—The position throughout the engineering, iron, and coal trades of this district remains without improvement, and the uncertainty as to the course of events with regard to the wages question in the coal trade induces an unsettled feeling as to the future. Some of the large users of fuel are taking advantage of the present excessively low prices to get in stocks, as a precaution against possible eventualities; whilst for pig iron makers are not anxious about committing themselves to engagements over any extended period, and generally there is a disposition to restrict operations to as narrow limits as possible, which necessarily checks the development of anything like speculative enterprise. The probable outcome of the miners' strike against a reduction in wages is being keenly anticipated here, as it will largely govern the action of the English coalowners with regard to wages; and the fact that the Miners' Federation have increased the special levy in support of the Scotch miners to 1s. per member per week, shows that they regard the struggle as a vital one, and that they are determined to use every effort to prevent any reduction whatever in wages.

A generally depressed tone continues to be reported throughout the iron market here, and at Tuesday's meeting there was again only a very limited weight of business stirring, whilst pig iron makers in most cases complain that, even where they are fairly well sold, their customers are only taking deliveries on account of contracts very indifferently. As regards pig iron, there is no change so far as local and district brands are concerned. Lancashire makers still quote nominally on the basis of about 39s. 6d. to 40s. for forge to 42s. for foundry, less 2½, at the works, but they remain practically out of the Manchester market, the delivered prices for which are about 42s. for forge to 44s. 6d. for foundry, and they are booking very little business of any moment, even where they have much more favourable rates of carriage. For district brands prices continue extremely low, Lincolnshire not averaging more than 38s. 6d. for forge to 39s. 6d. for foundry, with Derbyshire foundry readily obtainable at 44s. 6d. to 45s. 6d. net cash, delivered Manchester. The miners' strike in Scotland, and the damping down of some of the furnaces, necessarily has some effect upon outside brands offering here, and prices have shown a hardening tendency, but any appreciable advance is little more than nominal, as there is scarcely any business to really test prices. Good foundry Middlesborough is, however, not quoted under 44s. 4d. net cash, delivered Manchester, whilst as regards Scotch iron, some of the makers have withdrawn quotations altogether, and where there are sellers in the market, they are asking about 46s. for Eglinton to 49s. and 49s. 6d. for Glengarnock and Gartsherrie, net prompt cash, delivered at the Lancashire ports.

In the finished iron trade only the slowest possible business continues to be reported, forges not starting before Tuesday or Wednesday, and only just kept going hand-to-mouth with this restricted production. For Lancashire and North Staffordshire bars the quoted prices remain nominally at £5 10s. to £5 12s. 6d., delivered in the Manchester district, but it is exceptional where local makers are getting more than £5 7s. 6d.; Lancashire sheets can be bought at £6 17s. 6d. to £7 2s. 6d., and Staffordshire about £7 5s. per ton. The official list rates for Lancashire hoops remain at £5 17s. 6d. for random, and £6 2s. 6d. for special cut lengths, delivered Manchester or Liverpool.

Nut and bolt makers report a continued decreasing inquiry, with excessively keen competition to get hold of any orders that happen to come upon the market.

In the steel trade only a very quiet business comes forward, with prices about as last quoted, ordinary foundry hematites averaging about 52s. 6d., less 2½; ordinary basic billets £4 net cash, with steel boiler plates obtainable at £6 7s. 6d. to £6 10s., local makers who quote £6 15s. being altogether out of the market.

In the metal market there is perhaps more inquiry stirring at the reduced list rates for manufactured goods, but there is still no great weight of actual business doing.

The position, generally, throughout the engineering industries remains very much what I have reported for some time past. Only in exceptional cases are establishments more than very moderately off for orders, whilst new work still comes forward very indifferently, and the outlook for the immediate future shows no indication of any probable revival of activity.

The official programme in connection with the approaching visit of the Institution of Mechanical Engineers to Manchester has been issued this week, and the following papers have been offered for reading and discussion at the summer meeting, which will be held in the Owens College during the visit:—"Description of the New Electric Lighting Works, Manchester," by Dr. John Hopkinson, F.R.S., Member of Council; "Electric Welding," by Mr. Benjamin Alfred Dobson, Member of Council; "Description of Twin-screw Propellers with Adjustable Immersion, fitted on Canal Boats," by Mr. Henry Barcroft, of Newry; "Description of the Manchester Main Drainage Works," by Mr. William Thomas Olive, resident engineer; "The Manufacture of Standard Screws for Machine-made Watches," by Mr. Charles J. Hewitt, of Prescott; "Drilling Machine for Cylindrical Boiler Shells," by Mr. Samuel Dixon, of Manchester. The proceedings open with a reception of the Council and Members of the Institution by the Right Hon. the Lord Mayor of Manchester—Sir Anthony Marshall—and the Mayor of Salford—Sir Wm. H. Bailey—at the Owens College, on Tuesday morning, July 31st, to be followed by the reading and discussion of papers on that and the subsequent Wednesday morning, the visit extending over until Friday. On the Tuesday and Wednesday afternoons, excursions are to be made to various works of interest in the district; on Tuesday there is to be a conversazione in the Town Hall, by invitation of the Lord Mayor of Manchester; on Wednesday evening the Institution dinner is to be held at the Grand Hotel; on Thursday, excursions are to be made to various points of interest in the district, and in the evening the local members of the Institution have specially engaged the Theatre Royal, where a private operatic performance will be given, to which the members of the Institution are invited. On Friday there are to be excursions to Bolton, where several of the important cotton mills and machine and engineering works; to Horwich, where the Lancashire and Yorkshire Railway Locomotive Works; and to Crewe, where the extensive London and North-Western Steel and Locomotive Works are thrown open for inspection by the members.

In the coal trade only a very slow inland demand for all descriptions of fuel continues to be reported, and stocks go on rapidly accumulating, although very few pits are working more than three to four days per week. The increased demand for shipment, however, reported last week, is fully maintained, owing to the miners' strike in Scotland, and this is helping to clear away some of the surplus supplies, which would otherwise be coming upon the market, whilst it is also tending to steady prices somewhat, which might otherwise have shown a downward move. At the pit mouth best Wigan Arley coals remain at 11s. to 11s. 6d.; Pemberton, four feet and seconds Arley, 10s. to 10s. 6d.; with common house-coals ranging, according to quality, from 7s. for steam and forge descriptions up to 8s. to 8s. 6d. per ton. With regard to gas coals prices would seem to get weaker, if anything, as the season advances, and contracts which have been placed during the past week or so have in most cases been taken at very low figures; in some instances quite as low as those ruling last year, ranging from about 7s. for ordinary screened, up to 8s. and 8s. 6d. for the best screened gas coals at the pit mouth. The supplies of engine classes of fuel are generally plentiful, and for these, prices, if anything, are rather easier, common slack being readily obtainable at 4s. 3d. to 4s. 6d.; medium sorts, 5s. to 5s. 6d., with very best qualities quoted at from 6s. up to 6s. 6d. per ton.

In the shipping trade, as already stated, there is a fair amount of activity just now, and better prices have been got, ordinary Lancashire steam coal, delivered at the Garston Docks, or the High Level, Liverpool, fetching about 9s. to 9s. 3d. per ton.

*Barrow.*—There is no increase in the activity of the local hematite pig iron trade. Makers are indifferently employed, and have only thirty-six furnaces in blast. Some slight improvement may be realised by the Scotch strike, and by an increased demand for hematite on Scotch account, but while the pig iron trade may be benefitted by this cause, there will be a corresponding falling off in the consumption of native iron ore, which to the extent of several hundred tons is shipped weekly to Scotch smelters of hematite. Warrant iron is quoted at 44s., net cash sellers, and 43s. 11d. buyers. Makers' prices are unchanged at 44s. 6d. to 45s. 6d. net, f.o.b., for mixed Bessemer numbers. Stocks of warrant iron have increased during the week to the extent of 1320 tons, leaving stocks in hand 147,496 tons, or an increase of 52,873 tons since the beginning of the year.

Iron ore is in quiet local consumption. Ordinary qualities are quoted at 8s. 6d. per ton, better sorts at 9s. 6d., and picked samples at 13s. 6d. per ton net at mines.

In the steel trade there is not much life. Inquiries for steel rails are comparatively few, and foreign orders are especially scarce. Very few new consignments are in the market, and makers are not well sold forward. Steel for shipbuilding purposes is in fair but not brisk request, but makers are still fairly well sold forward on local account, while at the same time holding orders for Liverpool, Belfast, Scotch and other shipbuilding centres. There is not much doing in billets, tin bars, or hoops. Trade is nil in blooms, wire rods and slabs.

Shipbuilders and engineers are fully employed in most departments; but additional orders will soon be required, and if they are not soon forthcoming the initial departments of trade will be slack. There is a prospect of orders for some important high-class lines; but the general demand for new shipping tonnage is very small indeed, although probably ships could now be built at less money per ton than at any previous time in the history of the trade. There is not, however, much employment for shipping, and freights are low. A consignment of 12,000 tons of steel rails was fixed by steamers, from Barrow to Calcutta, at 8s. per ton.

The coal and coke trades are very quiet, and the volume of business doing is small. Prices are, however, steady at old rates.

The shipping trade shows again a falling off in tonnage. The exports of pig iron from West Coast ports last week reached 5505 tons, compared with 7390 tons in the corresponding week of last year, a decrease of 1885 tons. The aggregate shipments of pig iron for the year so far have reached 195,121 tons, compared with 132,868 tons in the corresponding period of last year, an increase of 62,253 tons. The exports of steel last week amounted only to 4266 tons, compared with 10,267 tons in the corresponding week of last year, a decrease of 6001 tons. The shipments of steel to date this year have reached 194,719 tons, compared with 239,404 tons, a decrease of 44,685 tons.

There is still a large number of unemployed skilled and unskilled artisans in the district.

## THE SHEFFIELD DISTRICT.

(*From our own Correspondent.*)

THE effect of the Scotch miners' strike is beginning to make itself apparent in the Yorkshire district, although not to the extent that was anticipated. Owing to the sudden advent of exceptionally warm weather, household coal is again somewhat depressed, many of the largest collieries producing steam coal, enjoying at present an abnormal demand, have consequently an unusual quantity of softs—that is household fuel—to get rid of. This has been severely felt for some time, particularly in West Yorkshire, where many of the manufacturers obtain supplies at very low prices. Should the Scotch strike continue, efforts will no doubt be made to dispose of the surplus of it in that direction. Prices in the neighbourhood of the coal-pits are well maintained, and the demand from the metropolis being fully up to the average, quotations remain unchanged. Coal by sea is going to London in less quantities, and this has the effect of benefiting Midland coal proprietors. Silkstones are making from 9s. 6d. to 11s. per ton; Barnsley house, from 8s. 6d. to 10s. per ton; Flockton, 8s. 9d. to 10s. per ton; inferior grades, from 8s. to 8s. 6d. per ton. The district pits are sending large supplies of steam coal to the Humber ports, the thick-seam collieries obtaining a better position with regard to this trade. Values remain steady, Barnsley hards keeping at 7s. 9d. to 8s. 6d. per ton; other qualities from 7s. per ton. Gas coal is in fair demand, at 7s. 6d. to 8s. per ton. Manufacturing fuel is plentiful, but there is little demand, and prices are low, good slacks making only from 4s. 6d. to 5s. 6d. per ton. Smudge and small coal in dull request from 2s. per ton. Coke quiet at from 9s. to 11s. per ton.

In consequence of an improved call for house coal from London and the South, prices have been advanced 6d. to 8d. per ton. One of the largest of the gas contracts, that of the Birmingham Corporation, was placed in the end of last week, at prices rather higher than for the previous year. A considerable portion of the order has again been secured by Messrs. J. and G. Wells, of the Eckington Collieries. Railway companies have generally arranged for contracts for the supply of fuel for the ensuing year at prices varying from 8s. 3d. to 8s. 6d. per ton.

There is a slight, but very slight, improvement in the iron and steel industries. More is doing in the rolling mills, caused by increased demand in the lighter staple trades. Hematite irons remain at from 51s. to 52s. 6d.; common forge iron is at 38s., both delivered at Sheffield. Bar iron is quoted at from £5 10s. to £5 15s.; Bessemer billets, £5 7s. 6d. to £5 10s.; ordinary iron sheets, £8 10s.; English dead softs wire rods £5 5s., and high carbon and rope rods £8 per ton. There is a considerable business doing in finished iron. The outlook in the shipbuilding trade is discouraging.

Sheffield manufacturers are in daily expectation of the tariff arrangements being settled in the United States. The agreement come to is expected to be about equivalent to a duty of 62½ per cent. all round, as compared with the 50 per cent. *ad valorem* in force prior to the McKinley measure. If this comes about the new tariff will be a considerable advantage compared with the McKinley Act, which imposed a duty upon pen and pocket knives of between 70 and 100 per cent. There is an expectation in local quarters that, as the result of a conference to be held, the tax will be reduced to 50 per cent. all round. Trade continues very quiet in the United States, although a good many orders are coming to hand now, in consequence of stocks being entirely exhausted. Sheffield trade with Spain is also in an unsettled state. Our treaty with that country terminated on June 30th, and as no fresh arrangement has been come to, the probability is that England will come under the maximum tariff, as Germany has done. Between Germany and Spain a war of tariffs is at present being carried on, the one country retaliating against the other.

The annual meeting of Messrs. John Brown and Co., Atlas Steel and Iron Works, Sheffield, was held on the 3rd instant, Mr. J. D. Ellis, J.P., the chairman of the company, presiding. The proceedings were of more than usual interest owing to this company having been somewhat exceptionally situated in regard to the great coal strike. The chairman stated that the outlook, with regard to their ordinary trades, such as axles, tires, and steel, was not any better than at the corresponding period of last year. With regard to the miners' strike, the shareholders could hardly imagine the difficulties the strike entailed upon the company. Their collieries were very large, raising 20,000 tons of coal per week. They had coal to last them six weeks, but the strike extended over sixteen weeks, and when their supplies were exhausted they had terrible difficulties to contend with. They had the ordinary expenses of the collieries, the maintenance of the staffs and horses, and in addition to that they had to consider the question of their workmen. Some of their neighbours, perhaps wisely, decided to shut up their works altogether, informing their customers that they could deliver nothing until the strike was over. The directors of John Brown and Co. did not think it wise to do that. They determined to consider their workmen, particularly as a very large number of them had only been working three days a week for a whole year before the strike occurred, and therefore had not been able to lay by anything for the calamity. The directors had therefore decided to keep the works going, and to give them employment one or two days a week as they could. Then, with regard to armour-plates, the Government had decided that they must adopt steel according to the Harveyised method. In 1886 the company had put down a large press, but under the Harveyised method the Bessemer process, for which John Brown and Co. had taken out the first patent, was not required. They had, therefore, to extend their Siemens-Martin plant. In the expectation of the very large orders to come, the directors had felt that it was not safe to depend upon a single press only. They therefore had decided to order another press from Messrs. Whitworth and Co., of Manchester. That would be a 10,000-tons press, which, when they got at work, would put them in the very best position for supplying the British and other Governments with Harveyised plates. Some idea of the magnitude of this press will be obtained from the fact that two of its pieces would weigh 80 tons each, and would have to be lifted above the uprights to a height of 100ft. Referring to the armour-plate tests which had taken place at Russia, Mr. Ellis mentioned that as the Russian projectiles were fired at a 6in. plate when the plate ought to have been 10in., it was not extraordinary that the plate should have been pierced. As far as the trials have gone, Messrs. John Brown and Co. had no reason to be dissatisfied with the result.

Mr. H. D. Pochin, J.P., vice-chairman, in seconding the adoption of the report, said that one-third of the whole money-getting power of the company was in armour plates, and the other third was in coal, so that two-thirds of the entire money-getting power was affected by the condition of trade last year. He mentioned that the 10,000-ton press now ordered would be the largest in this country, the only one equal to it being in America. The nearest to it in England was that of Messrs. Vickers, Sons and Co., which was an 8000-ton press. The cost of the 10,000-ton press would be, with its surroundings, £100,000. Two large departments recently added to the establishment were now in full operation. One of these was the Purves flue, which had now been fitted into 1800 ships. The other was the Serve tube, with which seventy-eight vessels were now at work. The outlook for the ensuing year was believed to be most encouraging. The dividend declared for the past year was 5 per cent., against 7½ for the previous year, the diminished return being entirely owing to the two causes mentioned—the absence of orders in the armour-plate department and the coal strike.

Captain Tressider, who is at present in Russia attending the tests of armour-plates, has been appointed a director of John Brown and Company, Limited, Sheffield. The chairman of the company, Mr. Ellis, stated that Captain Tressider's experience in the army was very great and valuable, and his technical knowledge—particularly in regard to the resisting power of armour-plates—stood as high as that of anyone else, if not higher at the present moment.

Mr. A. M. Chambers, J.P., President of the Coalowners' Federation of Great Britain, has been presented with a cheque for a handsome sum in acknowledgment of his services in connection with the sixteen weeks' coal war. The cheque was accompanied by a piece of plate for presentation to Mrs. Chambers. The plate was in the form of a silver loving cup, with two handles, a figure emblematic of "Peace" being placed upon the lid. The cup is handsomely chased, and bears a suitable inscription. Mr. Hewlitt, on behalf of the members, made the presentation, and Mr. Chambers, in acknowledging it, mentioned that he was once engaged in a coal war which lasted thirty-three weeks, and cost the life of his father and uncle. He felt deeply grateful to the coalowners for the way in which they had stood by him in the recent trying circumstances, and hoped, as his health had been much improved by his stay abroad, that he would still have strength to be devoted to their service.

## THE NORTH OF ENGLAND.

(*From our own Correspondent.*)

BUSINESS continues to be greatly interfered with by the disputes between labour and capital, which in some cases have led to strikes, and in other cases strikes are threatened. The chief labour difficulty in this district is the strike of the moulders and patternmakers at the shipyards and engineering establishments, a strike which has already lasted for fourteen weeks, and which does not give promise of an early termination. The men have refused to allow the dispute to be settled by a Conciliation Board, which the masters suggest shall be formed, and yet they blame their employers for the continuance of the stoppage. Operations are further hampered by the shipyard joiners striking work, and what is worse, these difficulties do not involve the stoppage of the men on strike only, but many more have to be paid-off, because the employers cannot get castings, &c., to go on with, and they cannot make further progress with the orders in course of execution. Both at the engineering works and shipyards is this the case, and some establishments are to be closed altogether within the next few days. Thus Messrs. William Gray and Co.'s central shipyard at West Hartlepool is to be closed on Saturday, according to notice given last Saturday. From the Central Marine Engine Works, at Hartlepool, a large number of hands were discharged on Saturday, because the firm can find no employment for them through their inability to obtain castings, and there is now not more than a fourth of the normal staff working. From Messrs. Richardson's Marine Engine Works at Hartlepool about 1000 men have had to be discharged, and the rest have gone on three-quarter time this week. At various shipyards vessels are on the stocks ready for their engines, but these cannot be obtained. On this account Messrs. Ropner and Sons have had to give notice that from Tuesday next their extensive shipyard at Stockton will be closed. Sir Raylton Dixon and Co., Cleveland Shipyard, Middlesbrough, have posted a notice that owing to the continuance of the joiners' strike the yard will be closed on and after Wednesday next, and no men will be further employed, except such as may be specially arranged with by the foremen of the different departments. Vessels are being sent abroad to have their woodwork completed, owing to the joiners' strike, and already five have been so sent from the Tees to Germany. It is to be regretted that no move is made to bring about a speedy settlement of a dispute so disastrous, not only to the shipbuilding and engineering industries, but also to the trades which are to a large extent dependent upon them. The spirit of the men is shown by a resolution passed last Saturday at a conference of moulders at Middlesborough. It is to the effect "That this conference recommend to all trades unionists on the North-East coast that it is their duty to abstain from working on any job in which a casting may be used which has not been cast, or the pattern for which has not been made by the men now on strike." Even were the strike ended at once it would be two or three months before work could be fully resumed at the shipyards, as builders would have to wait for the engines. But the men do not show a conciliatory spirit at all, as they think their position is better than it has been at any time during the strike.

Another difference between employers and employed which threatens to become serious is that about the adoption of the eight hours' shifts at the blast furnaces. The ironmasters have refused to grant this, and accordingly the men have decided to stop work for twenty-four hours on August 6th, so that they may hold a demonstration in favour of the shorter day. The employers do not see their way to give leave for such a stoppage; but nevertheless the men are determined at whatever cost to have the holiday, and on Monday—after a conference with the men—the ironmasters passed the following resolution:—"The ironmasters are of opinion that a stoppage of twenty-four hours will entail a most serious and far-reaching loss on the industries of the district. While they recognise that the men are entirely within their legal rights in giving notice to terminate the existing engagements, they hold that in so doing they are acting against the spirit of the sliding scale, and of all arrangements which have hitherto existed between the employers and the blast furnacemen. They regret to find that an attitude which appears to the employers to be so hostile in character should be adopted by the men, and they desire to record their protest against the course which it is intended to pursue. They take note of the intention of the men, as intimated by their representatives, to give notice on the 21st July to terminate their engagement on Saturday, the 4th of August, and they will consider what action they on their side will adopt under the circumstances." With regard to the eight hours' shifts, they have been adopted at two works in this district, and are promised at a third next month, these works being connected with the Ironmasters' Association, but admittedly the adoption is only an experimental one, and it is expected that it will need a twelvemonth's experience to determine the cost. It would seem the better plan for the blast furnacemen, instead of pressing for the immediate general adoption of the system, to wait the result of the experiment at the works that have adopted it, and then if successful they would have a very strong case.

Some improvement is noticeable in the demand for Cleveland foundry pig iron, which is due to the strike in Scotland, and prices are firmer, and are likely to be higher if the stoppage in Scotland is not speedily ended, as Cleveland foundry pigs will have to be taken by the Scotch founders, who, it is expected, will be able to keep their establishments going by importing the comparatively small quantities of coke which they need. This district will also profit by the strike in Scotland, in that there will be less competition for the continental trade, as the Scotch makers are having to stop their furnaces. A greater share of the continental trade will thus come to the North of England. But if the strike is favourable to Cleveland foundry iron, it will be just the opposite for forge pigs, and also hematite iron, of which less will be required for Scotland, seeing that nearly all the finished iron and steel works there will be closed; indeed, many are so already.

There will, however, be a little to counterbalance this, because our local finished iron and steel works will be consuming more, as they are receiving more orders from the Clyde shipbuilders.

The June statistics of the Cleveland Ironmasters' Association are somewhat disappointing, seeing that they show a considerably greater increase of stock than had been estimated—no less than 9178 tons, making 20,363 tons for the last two months, when there should have been a decrease. The increase was nearly all in Middlesbrough makers' unsold stocks, for other makers reduced theirs, and there were only very small increases in makers' and the public warrant stores. The production of pig iron was as follows:—Cleveland pig, 123,733 tons—decrease, 3931 tons on May; hematite, basic, and spiegel iron, 127,493 tons—decrease, 1518 tons; total, 251,226 tons—decrease, 5449 tons. The decrease is more than accounted for by June being a day shorter than May. The number of furnaces in operation showed no change, and of the 93 in operation 52 were making ordinary Cleveland iron, and 41 hematite, &c. The stock of Cleveland pig iron amounted to 163,666 tons—increase, 9178 tons. Of this, Middlesbrough makers held unsold 57,444 tons—increase, 9099 tons; and other North of England makers 6841 tons—decrease, 606 tons. In makers' stores there were 1335 tons—increase, 10 tons; in the North-Eastern Railway Company's stores 15 tons—unchanged; and in Connal's stores 98,031 tons—increase, 675 tons.

The pig iron shipments from Middlesbrough during June reached 82,052 tons—4418 tons less than in May, and 706 tons less than in June last year. About one-sixth of the pig iron now exported from Middlesbrough is hematite, the quantity being 14,568 tons in June, and 14,228 tons in May. To Germany, over 20,000 tons of pig iron were sent last month from the Tees, and to Scotland 25,818 tons.

The quotation for No. 1 Cleveland pig iron, which is sent mainly to the Continent, is 38s., while for prompt f.o.b. deliveries of No. 3 nothing below 35s. 6d. has this week been taken, and this is readily paid; indeed, consumers would give it for deliveries up to the close of the quarter, but producers will not sell so far ahead. This week's fluctuations in Cleveland warrants have been small, having ranged over no more than 2d. No. 4 Cleveland foundry pig is quoted 35s., and grey forge 34s. 6d., but both are obtainable at less. Mixed numbers of East Coast hematite pig are quoted 44s., but have been sold at 43s. 9d. Connal's, at June 30, had in stock 43,589 tons of hematite pig, 2875 tons increase for the month. Foreign ore is cheaper, 12s. 3d. per ton delivered Tees being the figure for average Rubio. Good blast furnace coke can be bought at 12s. 3d. per ton delivered at Middlesbrough furnaces.

Messrs. Bolckow, Vaughan and Company, the Clay Lane Iron Company, and the Cargo Fleet Iron Company have agreed with the Tees Conservancy Commissioners to reclaim nearly 300 acres of foreshore at Eston and Cargo Fleet. They will effect the reclamation by tipping their slag upon it, and for this they will pay 2d. per ton, to be divided among the Tees Conservancy Commissioners, the frontagers, and the Crown authorities. This will afford facilities for the erection of further works on the south bank of the river Tees. Land on which to deposit the refuse of blast furnaces is getting very scarce in the neighbourhood of Middlesbrough, and several firms have to send their slag out to sea.

The finished iron and steel trades are a little more active than they have been, owing to additional orders from Scotland, and prices are stiffer. Bridgebuilders are also better off. A Darlington firm has secured the order for steel bridgework for the Great North of Scotland line from Ellen to Cruden. The Blythe Dry Dock Company has commenced with the third graving dock, which will be capable of accommodating the largest vessels.

In commemoration of the fiftieth anniversary of the establishment of the firm of Bell Brothers, the officials connected with the commercial department, the Clarence Iron and Alkali Works, the collieries, ironstone mines, and limestone quarries, &c., and also the representatives of the workmen, on Saturday presented a congratulatory address and a valuable service of silver plate to Sir Lowthian Bell, Bart., F.R.S., the senior member and founder of the firm. It is fifty years since Messrs. Bell Brothers started as iron manufacturers, and over forty since they commenced as producers of Cleveland pig iron, erecting their Clarence furnaces in 1852, within two years after the discovery by Mr. Vaughan of the main seam of Cleveland ironstone. Towards the presentation over 4000 workmen employed by the firm contributed. The address referred to Sir Lowthian's work in developing the minerals, coal, ironstone, and limestone of Durham and Cleveland, and also in founding the salt trade of Tees-side. It was stated that since the Clarence furnaces had been built, they had converted into Clarence pig iron over 20 million tons of Cleveland ironstone, and Sir Lowthian himself remarked that his firm had during the half century at their various works used no less than 74 million tons of minerals. The Council of the Middlesbrough Chamber of Commerce at its meeting on Wednesday, passed a resolution congratulating Sir Lowthian on his having attained the 50th year of his business life. It was stated that the Cleveland district was under great obligations to him for the investigations he had undertaken with a view of cheapening and improving the manufacture of the staple product of the district.

The coal trade is improving, and the higher prices generally asked are being maintained. Fully 11s. per ton, f.o.b., is paid for best Northumberland steam coal, or 1s. more than was recently paid, and some firms are quoting 12s. Best Durham house coals have been put up to 8s. per ton, f.o.b.

## NOTES FROM SCOTLAND.

(*From our own Correspondent.*)

THE iron market has been in an irregular state this week, owing to the miners' strike. Business in warrants is limited, and while the varying opinions held with reference to the strike affect the market from day to day, the fluctuations in prices are within a comparatively narrow range. Scotch warrants have sold from 41s. 11½d. to 42s. 1d. cash; Cleveland, 35s. 3½d. and 35s. 4d., the quotations of Cumberland warrants being 43s. 11d. and 44s., and of Middlesbrough hematite warrants 43s. 3d. and 43s. 0½d. There is still a marked absence of speculation in warrants.

The attitude of the ironmasters with regard to the strike is very decided: they are resolved to close down their furnaces rather than make any concession to the colliers in their employment, and in the course of the past week a large proportion of the furnaces has been damped out. The production of basic iron is again stopped altogether. Monkland has been coming into request, and Gartsherrie is so scarce that the makers are keeping in as many furnaces as possible. Some of the lower priced special brands are in improved demand, and all of them have been rising somewhat in price. G.M.B. f.o.b. at Glasgow No. 1 is quoted 43s. 6d. per ton; No. 3, 42s. 6d.; Carnbroe, No. 1, 44s. 6d.; No. 3, 43s. 6d. Calder and Summerlee No. 1, 52s.; No. 3, 47s.; Gartsherrie No. 1, 52s. 6d.; No. 3, 47s.; Clyde No. 1, 49s.; No. 3, 46s.; Coltness No. 1, 54s. 6d.; No. 3, 50s. 6d.; Glengarnock at Ardrossan No. 1, 50s.; No. 3, 47s. 6d.; Eglinton No. 1, 48s. 6d.; No. 3, 44s. 6d.; Dalmellington at Ayr No. 1, 45s. 6d.; No. 3, 44s.; Shotts at Leith No. 1, 53s. 6d.; No. 3, 49s. 6d.

The shipments of pig iron from Scottish ports in the past week have been much larger than usual, amounting to 10,248 tons, compared with 5603 in the corresponding week of last year. Of the total, Holland took 1225 tons, United States 25, Canada 200, South America 40, India 110, Australia 270, France 60, Italy 400, Germany 703, Belgium 10, Spain and Portugal 100, China and Japan 40, other countries 1018; the coastwise shipments being 6037, against 2972 in the same week of 1893.

The malleable iron and steel trades are depressed, a large number of the works is already closed, and will not re-open until after the strike is over. There is at the moment practically no market for finished iron and steel, both foreign and home requirements being small, and maker, merchant, and shipper acting with caution. Prices are nominally unaltered.

The iron and steel manufactured goods shipped from Glasgow in the past week embraced locomotives worth £7000, sewing machines £7664, other machinery £7815, steel goods £14,918, and miscellaneous iron goods £22,736.

There has been a great falling-off in the coal shipments, the total quantity despatched from the various ports being only 79,643 tons, compared with 154,361 in the preceding week, and 156,986 in the corresponding week of last year. An advance has occurred in the prices of coals, but it is very irregular, and only in cases where supplies are urgently wanted are buyers consenting to pay the advanced rates. The miners' strike is very complete, there being very few men working.

During the past month 36 vessels of 37,226 tons were launched from the Clyde shipyards, against 29 vessels and 22,727 tons in June, 1893. The output of the six months has been 135 vessels and 168,818 tons, compared with 132 vessels and 121,700 tons in the first half of last year.

## WALES AND ADJOINING COUNTIES.

(*From our own Correspondent.*)

THE number of bodies brought up from the Albion Colliery now totals 279, and it is currently reported that eighteen are still unaccounted for. If true, this will bring the death roll close up to 300, as suggested in this column last week. The inquiry is now about to begin, before a selected jury, and strenuous efforts will be made to trace the cause. It is not at all unlikely that, as many of the morning shifts continued to work on in the afternoon shift, some act of rashness, such as opening a lamp to light a pipe, was the first fatal cause. An invention by Mr. D. Evans, of Merthyr, which has just been patented, is now being discussed by mining engineers and colliery managers, as promising to effectually prevent the tampering of the locks of miners' lamps. Once locked, it is intact until handed back again by the collier. Such an invention is urgently needed, especially, as it must be considered the coal working of Wales is entering upon a critical epoch. Pits are deeper, acreage of working larger, output greater, and the speed of output is immense.

Coalowners and colliery managers are too well aware of the cost of these great explosions—apart from questions of humanity—to run any risk for mere questions of outlay. The mechanical appliances are of the best; timbering is ample, wire ropes rigidly tested. Their foremen are vigilant, and their action is supplemented by careful inspection, periodically, of the colliers selected for the purpose.

Local discussion is active, and the inquest is being awaited with great interest, especially as is pointed out, that other large collieries in the district are being worked under similar conditions to the Albion, and the output great and incessant.

The explosion has had the effect of sending coal prices up, the supply being insufficient to meet the demand, and this failure of the Albion output and the Scotch strike threaten still further to advance prices. At present, prices are distinctly 1s. per ton better than they were a month ago. Best steam is now quoted at 12s. to 12s. 3d., and even seconds 11s. to 11s. 3d., while best Monmouthshire is firm at 10s. 6d. to 10s. 9d. Little if any "dry coal" can be obtained under 10s. 6d., the price at which best ruled a short time ago. Best small is at 6s. 9d. to 7s., and ordinary 5s. 9d. to 6s.

House coal continues to keep up remarkably well. The time has now arrived when, usually, demands are sensibly less, and prices low. This week best house is selling in Cardiff at 11s. to 11s. 3d.; No. 3 Rhondda, 10s. 6d. to 10s. 9d.; brush, 9s.; small, 7s. to 7s. 3d.; No. 2, Rhondda, 9s.; through, 7s. to 7s. 6d.; small, 5s. 3d. to 5s. 6d. At all ports the shipments of coal last week were large, but not so great as they would have been if more coal had come to hand. Swansea total was a long way above the average: 48,473 tons; patent fuel, 6773 tons. In all the Swansea exports showed an increase of 20,000 tons above that of the corresponding week last year.

At Newport, too, the coal shipments were very large. The June total at the Alexandra Dock was 297,975 tons, the heaviest on record. The June total 1893 was 243,751, so that the last month showed an increase of no less than 54,223 tons.

No change of importance has occurred in coke, though the improving character of the iron and steel trades gives reasonable hope for better prices. Cardiff prices this week are:—Furnace, 15s. 6d. to 16s. 6d.; foundry, 17s. 6d. to 18s. 6d.; and special foundry, 20s. to 20s. 6d. Patent fuel is in better demand at Cardiff—prices, 10s. 9d. to 11s. 6d. Prices have an upward tendency. Pitwood tolerably firm, 15s. to 15s. 3d. per ton.

Iron ore is arriving in large quantities at Cardiff, and Newport, Mon. Some of the notable cargoes have been 2071 tons to Tapson and Son, 1800 tons Blaenavon Company. Dowlais and Cyfarthfa have also been receiving large consignments. Present prices Cardiff are:—Best Rubio, 11s. 6d. to 11s. 9d.; Garucha, 11s.; Tafna, 11s. to 11s. 3d.; Porman, 10s. 6d. to 10s. 9d.

A moderate degree of activity has begun to characterise the principal ironworks, and last week a fair quantity of merchant bar, sheet bar for tin-plate works, rails, and small goods was worked off. The principal features were an increased make of bar to the Swansea and neighbouring works, rails to Barry and to Christiania. The last-named was a cargo of 800 tons.

On 'Change, Swansea, it was commented upon that the steel trade of the district remained unaltered. Glasgow pig iron was quoted at 42s. 1d.; Welsh bars, £5; sheet steel and iron, £5 5s. to £6 10s.; steel rails, £3 15s. to £4 for heavy; light, £4 10s. to £5 10s. Bessemer steel: tin-plate bars, £4 to £4 2s. 6d.; Siemens best, £4 2s. 6d. to £4 5s.; seconds, £4 to £4 2s. 6d.; all delivered in the district, cash less 2½.

There is no change to report in tin-plate, only that shipments are larger; but booking for forward delivery has not improved to the extent desirable, and prices only show a slight advance. Bessemer now realises 10s. 4½d. to 10s. 6d.; Siemens, coke finish, 10s. 6d. to 10s. 9d.; best charcoal, 11s. 9d. to 12s. 9d.; ternes, per double box, 28 by 20 C.: 20s., 21s., 23s. There is fair ground for expecting better trade in tin-plates, as with the settlement of the tariff question—fixing the date when the reduced duty will come into force—forward business is sure to increase. One of the worst symptoms, however, is the attitude of some of the men; and employers openly complain that there is little hope of good business being done, so long as men do their best to intimidate others from working. This perversity has prevented several re-starts of late.

Last week Swansea shipped 79,643 boxes of tin-plates, and received from works 70,695 boxes. Stocks now have fallen to 273,602 boxes.

A test action was brought at the Glamorgan Assizes this week by Mrs. Brown, widow of one of the sufferers by the Taff Vale railway accident, August, 1893, against the directors of that company. Her claim was damages for the loss of her husband, which counsel, on her behalf, contended was due to the negligence of the company. Mr. Abel Thomas, Q.C., M.P., and Mr. Walter Tyrell appeared for the plaintiff, and Sir R. Webster, Q.C., M.P., Mr. J. E. Banks, and Mr. Bailhade represented the defendants. The result of a two days' action, and the evidence of leading experts, that of Mr. Riches the locomotive superintendent of the Taff Vale, and other prominent authorities, was a verdict for the company.

The progress of electrical appliances in collieries and of electric lighting in towns is becoming marked. For a number of years the Ocean Collieries have used the electric light, and this is steadily on the increase, and of late has been conveyed to villages belonging to the company. In the Park pit twenty-one lamps are placed, at the Dare pit sixty-five are underground. The engine there—15 nominal horse-power—is working a Crompton patent dynamo by means of countershafting. The Plymouth Collieries, which may be said to have been singularly fortunate by their early adoption of the electric power, are winding from a considerable distance by the same agency, and in the lessened number of horses used have realised substantial benefits alone.

The directors of the Rhymney Iron Co. have issued their report upon the year's transactions to March 31st, 1894, and from this I note that after payment of August dividend and debentures, a balance is shown of £78,950. From this sum an interim dividend was paid in January of ½ per cent., amounting to £4452, and the directors now recommend a further dividend of 3 per cent., making 3½ per cent. for the year, a very satisfactory notification, which I am only too happy in scattering broadcast, as the Rhymney shareholders are numerous and widely spread. The report shows cogently that by stoppage of the steel works, and the better development of the large coalfield owned by the company, this satisfactory state of things has been brought about, and now that the mineral development is in such good hands, still better may be looked for in the near future.

I learn, with regret, that the hauliers at Plymouth meditate a strike.

## NOTES FROM GERMANY.

(*From our own Correspondent.*)

THE accounts that come in from the different iron markets show a slight decrease in the demand for most articles. A giving way in quotations has even been noticeable in some instances, producers being extremely anxious to secure the few orders that are offering. Home as well as foreign inquiry having considerably lessened during the past week, there is but little business of importance transacted on the Silesian iron market. The falling off in demand is chiefly felt in the malleable iron branch, which had, hitherto, maintained a very satisfactory condition. Prices are weak, but no actual going down has as yet been reported.

The total output of the collieries in Upper Silesia has been in 1893 17,095,531 t., worth M. 91,811,797, against 16,431,540 t., worth M. 89,328,998 in the year before, which is equal to an increase of about 4·04 per cent. Consumption is stated to have been 17,087,081 tons, showing an increase of 666,746 tons against last year. In the mining district of Lower Silesia, total production of the collieries amounted to 3,569,125 tons in 1893, against 3,411,753 tons in 1892, of which 3,120,716 tons were sold at the average price of M. 7·37 per ton.

At the present moment the Austro-Hungarian iron market appears to be the only one that can boast of a lively activity in most departments. Although fresh orders are coming in rather less frequently than during former weeks, the greater part of the works are, nevertheless, vigorously engaged on orders previously booked. In prices no change has taken place, but there is much firmness exhibited in the quotations for both raw and finished iron.

A pretty satisfactory business is still being done on the French iron market generally, some branches not having been so well employed for months as they are now. This has a direct effect on prices, which show considerable firmness, and it is very likely that there will be a general improvement in quotations before long. The works of the Nord are reported to have formed a plate convention recently.

On the Belgian iron market there is not the slightest improvement in business noticeable, prices remaining weak and pointing in a downward direction. The general tone is naturally depressed, the more so as there appears to be little prospect for an improvement in the immediate future. The situation of the Rhenish-Westphalian iron market has, on the whole, not changed since last week, buyers still showing some reserve, which is, however, not very keenly felt at the present moment, because there has been a sufficient number of orders secured previously, which will keep their works in regular though not remunerative employment. With the exception of some favoured sorts, pig iron shows a falling off in demand lately. The works of Luxemburg-Lorraine get their coke at much lower rates than the Rhenish-Westphalian firms, and are thereby enabled to offer pig iron at prices considerably below those quoted by the Westphalian makers, who find it almost impossible to compete with their more favoured rivals. On the malleable iron market there is likewise not much animation noticeable, most articles meeting with but limited demand; there is also considerable weakness reported in prices. Both consumers and dealers hold back with their orders as much as possible, finding that makers, being rather hard up for new work, generally give way in their prices when an order of some weight is concerned. Under such circumstances an advance in quotations is simply out of the question for the present. Bars and girders are in comparatively fair request, while hoops show a decided decrease upon the week. The plate mills are, on the whole, quite well employed, and sheets are likewise rather brisk of sale, but it is impossible to carry the slightest advance in prices. The wire trade is quiet so far as home demand is concerned, but large lots have recently been ordered from abroad. Since last week the situation of the foundries and machine factories has in no wise altered; the rail department will be fairly well employed for some time, the long expected orders for 80,000 t. rails and 25,000 t. sleepers having finally been given out by the Government.

The Association des Ingénieurs sortis de l'Ecole de Liège, who paid a visit to the iron and coal producing district of Rheinland-Westphalia last year, have now sent their German hosts an invitation to come over and inspect the different departments of iron industry in Belgium, and at the same time visit the Antwerp Exhibition.

EIGHT HOURS DAY AT THE DOCKYARDS.—A new departure was made at the Royal Dockyards on Monday, when the average eight hours day or forty-eight hours week came into operation. For purposes of account in paying the wages, the week is to be reckoned as five and a-half days, instead of six as heretofore. The working year will consist of 313 days, and for women employed in the ropery and colour loft 307 days. The only immediate advantage gained by the dockyard men is that they will leave off work at twelve noon on Saturday. The shorter days generally do not commence till the autumn.

THE TRAMWAYS INSTITUTE.—The annual meeting of this Institute commenced on Thursday. One of the first papers read was on the "Soulerin Automatic Vacuum Brake for Steam Tramways," by Mr. George Cawley, M.I. Mech. E. The paper described the general action and construction of this pneumatic brake, and gave some particulars of its working on the Paris-St. Germain tramway. Briefly, the automatic Soulerin brake comprises:—A main brake-pipe, an auxiliary reservoir, a brake diaphragm vessel or brake cylinder, a distributor, and an ejector for producing the vacuum. Combined with the ejector is a driver's brake-valve, The apparatus works as follows:—As long as the brakes are to be "off" a vacuum is created and maintained by means of the ejector in the main brake pipe and auxiliary reservoirs. Then the main brake pipe and auxiliary reservoirs communicate through the distributor, and the external air can enter freely into the diaphragm vessels. To apply the brakes, the driver causes external air to enter the brake pipe by means of his brake valve and thus puts in motion the movable parts of the distributors by means of which the brake diaphragm vessels or cylinders are then put in communication with their corresponding reservoirs, and the brakes are applied by the atmospheric pressure acting on the outer surface of the diaphragms. To release the brake the driver admits steam into the ejector, and then creates afresh a vacuum in the brake pipe. The movable parts of the distributor—which is synonymous with the triple valve of the air pressure brake—then resume their former positions, and atmospheric pressure entering the brake diaphragm vessel, the brakes are released. The Soulerin brake has been largely adopted for railway purposes in France, and the author states, is particularly efficacious in that the pressure of the blocks on the wheels can be graduated with any necessary degree of precision.

## LAUNCHES AND TRIAL TRIPS.

On Monday there was launched from the Cleveland Dockyard of Sir Raylton Dixon, and Co., Middlesbrough, a very fine steel screw steamer which has been built to the order of Messrs. David McIver, Sons and Co., of Liverpool and London for their River Plate Line. This is the first of three sister vessels which these builders are at present constructing for the same firm, and all the steamers have been specially designed and fitted for the River Plate trade. The accommodation for the passengers will be fitted up in the poop, and will be of the most comfortable description, special attention being given to the efficient ventilation of all the rooms. A plentiful supply of water for the baths, lavatories, &c. is provided, and, in fact, everything possible will be done to minimise the discomfort of steaming through the tropics. The vessel is of the partial awning decked type, with long raised quarter deck and poop, and has been built under special survey for Lloyd's 100 A1 class, the principal dimensions being:—305ft. by 41ft. 3in. by 20ft. 3in., with a deadweight carrying capacity of over 3500 tons on a very light draught of water, and the deck houses, boats, beams and other erections are so arranged that the steamer can be promptly adapted for the purpose of carrying cattle. The engines will be fitted by Messrs. Blair and Co., of Stockton on Tees, the sizes of cylinders being 23in., 37in., 61in. by 42in., with two large steel boilers working at 160 lb. pressure per square inch, and as the vessel is of fine lines a good sea speed will be maintained. She will be rigged as a fore-and-aft schooner with Sidgwick's patent hinged topmasts, by means of which the upper portion of the masts can be immediately lowered when the steamer is required to pass under any obstructions to navigation, such as the bridges of the Manchester Ship Canal, &c. The vessel has been built under the superintendence of Mr. Roscoe, of Liverpool, consulting engineer to the owners. A large and influential company witnessed the launch, amongst those present being Mr. David McIver, Mr. and Mrs. Robert McIver, Lady Dixon, Mr. C. Livingston, &c., and as the steamer was leaving the ways she was named the Saxony by Mrs. R. McIver, of Rothay Bank, Ambleside, who was presented by Sir Raylton Dixon with a beautiful bouquet of choice orchids.

The s.s. Turret Bell was launched from the the Yard of Messrs. William Doxford and Sons, of Sunderland, on the 3rd inst, having been built to the order of Messrs. The Turret Steam Shipping Co., of Newcastle—Messrs. Petersen Tate and Co., managers—and will receive the highest class in the British Corporation and Bureau Veritas registries.

## THE WEARING AWAY OF METAL PLATES BY THE ACTION OF STEAM JETS.

In an article on this subject by Mr. J. Walter—*Chem. Ind.*—the author states that he was led to the consideration of this subject by the behaviour of a steam-jacketed copper boiling pan. The copper pan was originally 8 mm. thick, and the steam entered the jacket at its lowest point. Being rather too small, the copper pan, after it had been at work for some years, was replaced by a rather deeper one, but one which in all other respects was exactly similar to the original pan. After the second pan had been in use for about a year, a hole was blown through the bottom, opposite the steam inlet to the jacket.

Believing that the mishap was due to the metal having been worked down too thin at this point, a third pan was made, slightly thicker—12 mm.—which was carefully measured all over, before putting into use.

To avoid a second accident the pan was tested from time to time, and after about fourteen months' work it was found that the bottom had been reduced to the thickness of paper.

This time the author attributed the wear to the hydrochloric acid used for cleaning out the pan. He had previously noticed the "pitting" produced on iron plates by the action of steam jets, and, although he could not in this case trace the wear to the steam jet, he placed the steam inlet at the side as a precaution. Some eleven months later he was convinced that the wear was due to the steam jet, as he found the pan again worn away; not at the bottom, but opposite the jet. The reason the original pan lasted so much longer is due, the author thinks, to it being shallower than the others, and therefore not so near to the steam inlet, and not subjected to such intense action. The author mentions a similar case that occurred with a lead-lined vessel which was heated by blowing in steam from pipes, perforated with rows of holes on each side, fastened to the bottom of the vessel by lead straps. From the stirring of the contents of the vessel one pipe got twisted, whereby the row of holes on one side pointed downwards. Very shortly the steam jets issuing from them pierced a row of holes through the lead bottom.

It is pointed out that the action of a steam jet is similar to that of a sand blast. In the former the abrading particles, instead of being sharp grains, are minute particles of water and rust, &c., from the pipes. Besides the purely mechanical abrasion there is also chemical action. The steam carries with it air, which oxidises the freshly-exposed surface, and the oxide film thus formed is more readily removed than the metal itself. The appearance of holes produced by the impinging of steam jets on to copper and cast iron plates is described, and the author concludes by pointing out that once the cause of such wearing away is recognised, its prevention becomes easy.

This prevention can be effected by placing over the point of impact thick metal discs about 200 mm. diameter; by making the direction in which the steam enters parallel to, instead of across, the jacket space; or by placing a thimble, closed at the top and perforated at the sides, over the steam inlet.

---

According to Professor Bauschinger, the adherence between iron and Portland cement is as much as 625 lb. per square inch.

## THE PATENT JOURNAL.

*Condensed from "The Illustrated Official Journal of Patents."*

### Application for Letters Patent.

*** When patents have been "communicated" the name and address of the communicating party are printed in italics.

*21st June*, 1894.

11,971. Handles for Skipping Ropes, J. and L. Baron, Douglas.
11,972. Detachable Corset Busks, T. H. Parker, Stourbridge.
11,973. Preparing Concrete, J. Stow, Hessle.
11,974. Cycle Saddles, H. Williams, Manchester.
11,975. Mechanism of Small-arms, W. H. Brighton, London.
11,976. Burner, E. E. Donald, Ipswich.
11,977. Furniture, J. C. Willis, Leeds.
11,978. Tap, H. E. Blakeborough and J. H. Rhodes, Stockton-on-Tees.
11,979. Brushes for Dynamos, W. vom Braucke, Stockton-on-Tees.
11,980. Window Sashes, J. Lakin and C. Johnson, Redcar.
11,981. Plug for Tobacco Pipes, J. Stephens, Tunbridge Wells.
11,982. Spinning Machinery, J. and R. S. Dawson, Bradford.
11,983. Gas Engines, J. Mackintosh, Dundee.
11,984. Pneumatic Tires for Cycles, J. T. Grey, South Shields.
11,985. Flyers for Balling Machines, J. P. Dalby, Leeds.
11,986. Miners' Safety Lamps, T. Woods, Liverpool.
11,987. Printing Machines, A. Jubb and J. Chalmers, Huddersfield.
11,988. Sulphur, G. S. Albright and J. J. Hood, London.
11,989. Bicycle Tires, E. Brown and S. Brown, Birmingham.
11,990. Stone-breaking Hammers, T. Evans, Birmingham.
11,991. Apparatus for Filtering Sewage, W. Evans, Manchester.
11,992. Binders for Books and Papers, J. M. Arnot, Edinburgh.
11,993. The Invisible Hook and Eye, E. and C. Mackenzie, Inverness.
11,994. Parallel Vices, J. Adamson and V. Lister, Woolwich.
11,995. Working Electric Telegraphs, W. Thomson, Glasgow.
11,996. Oil Lamps, C. Hide, Worthing.
11,997. Explosive Engines, J Fielding, Gloucester.
11,998. Printing Machine Cylinders, W. H. and A. P. Dawson, and J. Stott, Yorkshire.
11,999. Operating Organ Swells, H. J. Weintz and J. Willimont, Suffolk.
12,000. Manufacture of Railway Chairs, A. E. Muirhead, Glasgow.
12,001. Transmitting Signals between Railway Carriages, J. Murrie, Glasgow.
12,002. Pedals for Velocipedes, H. E. Wollmer, Manchester.
12,003. Hygroscopic Regulators for Humidifiers, J. Wallace, Manchester.
12,004. Buffering Apparatus, W. S. Laycock, Sheffield.
12,005. Washing Machine, T. B. Grant, London.
12,006. Fixing Electric Light Casing, C. Bishop, Liverpool.
12,007. Brooms and Brushes, A. M. F. Thatcher, London.
12,008. Chain Wheels of Cycles, J. Barratt, London.
12,009. An Automatic Electrical Switch, W. R. V. Marshall, London.
12,010. Curtain Stretcher, P. M. Hartpence, London.
12,011. Automatic Alarm Box, J. H. Smith, London.
12,012. Releasing Iron Tubes from Mandrels, R. Wootton and B. Hewitt, Birmingham.
12,013. A New or Improved Cloth, M. Lobley, London.
12,014. Printing Roller, L. Edwards, London.
12,015. Lamp Bracket for Cycles, A. E. Attack, Bedford.
12,016. Self-closing Collarettes, H. W. Bamford, London.
12,017. Suspending Trousers, &c., E. Beaumont, London.
12,018. Jets for Lime Light, J. E. Anderson and A. Wrench, London.
12,019. Golf Clubs, C. J. Jacobs, London.
12,020. Fastenings for Brooches, H. J. Cook, London.
12,021. Closing and Opening Gas Pipes, C. Weuste, London.
12,022. Soap Frames, A. E. Benjamin, Liverpool.
12,023. Envelopes for Transmission of Money, D. H. Fisher, Liverpool.
12,024. Refrigerating Apparatus, &c., M. Frank, London.
12,025. Fire Extinguishers, J. Tombeur, London.
12,026. Cigar or Cigarette Holders, D. H. Fisher, Liverpool.
12,027. Musical Instruments, F. Pietschmann, Liverpool.
12,028. Pneumatic Tires, T. Sloper, London.
12,029. Sewing Machines, D. M. Gerbaulet, London.
12,030. Valve Gear for Engines, F. Lamplough and T. P. Borden, London.
12,031. Material for Umbrellas, &c., W. H. Rooke, London.
12,032. Weighing Apparatus, H. H. Lake.—(*L. Berthon, France.*)
12,033. Automatic Smoke Consumer, &c., J. Butler, London.
12,034. Walls and Partitions of Buildings, E. Reiss, London.
12,035. Spindles for Spinning Machines, E. J. Fenderson and A. A. Coburn, London.
12,036. Tubular Boiler Steam Engines, J. Angus, London.
12,037. Manufacture of Figured Fabrics, F. Boyer, London.
12,038. Pneumatic Tires for Cycles, R. S. Anderson, London.
12,039. Trusses, A. Strauss, London.
12,040. Clip or Holder, E. Murrle, London.
12,041. Separating Oil, &c., from Steam, E. Austin, London.
12,042. Coin-freed Apparatus, C. A. Kaichen, London.
12,043. Convertible Billiard Tables, W. Kitteridge, London.
12,044. Toy Puzzle, A. A. Newbigin, London.
12,045. Secondary Batteries, A. Schanschieff, London.
12,046. Shaping Glass Objects, K. E. Grützner and B. A. Gruhl, London.
12,047. Carbonisation of Rags, A. J. Boult.—(*G. Schüll, Germany.*)

*22nd June*, 1894.

12,048. Artificial Fuel, W. H. Biggs and R. R. Greenhow, Cardiff.
12,049. Apparatus for Teaching Music, J. McGuinness, London.
12,050. Advertising Apparatus, W. Timns and R. Smith, London.
12,051. Billiard-cue Tips and Door Stops, C. T. Kempton, London.
12,052. Regulating Steam Supply, G. M Williams, London.
12,053. Producing the Tone of a Banjo, A. J. Jones, Birmingham.
12,054. Invalid Beds and Couches, A. C. Roper, London.
12,055. Hair-curler, W. W. Tambs, Birmingham.
12,056. Manufacture of Sheet Glass, R. M. Wight, Bradford.
12,057. Lids of Axle-boxes of Vehicles, J. Donnelly, Longport.
12,058. Appliance for Holding Reins, H. Machell, Dewsbury.
12,059. Steel Castings for Ships, J. and J. E. Muir, Liverpool.
12,060. Wind Motors, W. J. S. Barber-Starkey, Manchester.
12,061. Woven Quilts, W. A. Moore, Manchester.
12,062. Railway Fog Signals, T. Jenkins and S. Illidge, Birmingham.
12,063. Wheels for Vehicles, A. Smallwood, Birmingham
12,064. Wheels for Road Vehicles, &c, J. Main, Glasgow.
12,065. Welding the Joints of Pipes, J. G. Stewart, Glasgow.
12,066. Oil Stoves, W. Reynolds and C. H. Sherer, Coventry.
12,067. Constructing Steamships, T. Mercer, Liverpool.
12,068. Appliance for Peeling Potatoes, E. B. Pallett, Bristol.
12,069. Cleaning Cotton Seed, J. Bibby, Liverpool.
12,070. Covers of Pipes, W. Pearce, Birmingham.
12,071. Hay-making Machines, J. F. Phillips, Lancashire.
12,072. Manufacture of Soap, J. P. F. Field, London.
12,073. Drawing up Fires, A. and W. H. Heaton, Bradford.
12,074. Apparatus for Boiling Sugar, W. H. Percy, Bristol.
12,075. Making Ships' Fenders, R. Cole and F. Cole, Bristol.
12,076. Mouse-trap, Truttmann and Francis, Newcastle-on-Tyne.
12,077. Cigarette-making Machines, A. L. Munson, London.
12,078. Fire-escapes, W. Rose and O. F. Vollhard, Manchester.
12,079. Automatic Tipper for Closets, T. Hargreaves, Manchester.
12,080. Mattresses, V. Czerink and P. Mattlach, Glasgow.
12,081. Egg Safety Carrier, A. Neil and J. Coats, Govan.
12,082. Shields for Ordnance, W. Skerry, Newcastle-on-Tyne.
12,083. Vermin Trap, A. Hill, Hayward's Heath.
12,084. Explosives, D. Hickie and G. F. Beutner, London.
12,085. Cartridges, H. Güttler, London.
12,086. Making Bicarbonate of Soda, H. R. Angel, London.
12,087. Railway Fog-signalling, R. Brown, Brentford.
12,088. Guards for Carving Forks, F. Buckland, Thornton Heath.
12,089. Book Support or Book Holder, C. L. Work, London.
12,090. Decorating, W. W. Colley and Colley's Patents, Ld., London.
12,091. Knitting Machines, H. Verges, London.
12,092. Spanner, R. Wootton and B. Hewitt, Birmingham.
12,093. Carpets, &c., G. Barker.—(*M. J. Whittall, United States.*)
12,094. Stop Cocks and other Taps, W. B. Press, London.
12,095. Manufacture of Boots and Shoes, T. Field, London.
12,096. Thrashing Machines, &c, W. McKenzie, London.
12,097. Cartridges for Aerating Liquids, G. Bamberg, London.
12,098. Automatic Sash Fastener, E. F. Rawlins, Richmond.
12,099. Dynamo-electric Machines, H. F. Joel, London.
12,100. Electrical Signalling, J. W. Sunderland and G. Bilbrough, London.
12,101. Bending Tubes, W. B. Leachman and H. H. Grenfell, London.
12,102. Lamp, B. Lietar, Brussels.
12,103. Storing Explosive Liquids, C. A. Mesenhol, Germany.
12,104. Motors for Cycles, A. J. Boult.—(*La Société Française Des Cycles "Gladiator" and P. Barbé, France.*)
12,105. Watch, W. P. Thompson.—(*F. Masi and A. Cano, France.*)
12,106. Pumps, P. Stahl, London.
12,107. Preventing Corrosion in Boilers, A. F. Law.—(*C. Law, United States.*)
12,108. Regulators for Gas or Water, J. L. Dupont, London.
12,109. Heads of Tripods for Cameras, J. E. Touch, London.
12,110. Armlet, E. Murrle, London.
12,111. Constructing Hinge Joints, Z. Leglay, London.
12,112. Traps for Vermin and other Animals, A. Diss, London.
12,113. Cycles, A. T. Lyne, Old Southgate.
12,114. Camera Shutters, E. T. Hughes.—(*L. F. Eiden, United States.*)
12,115. Ladies' Evening Dresses, H. S. Malet, London.
12,116. Horseshoes, J. Terry, London.
12,117. Fastening for Envelopes or Bags, A. Eade, London.
12,118. Limelight Jets, W. A. Dawkins, Birmingham.
12,119. Photographic Cameras, W. A. Dawkins, Birmingham.
12,120. Cigar Cases, A. Stoecker, Germany.
12,121. Cigar Boxes, A. Stoecker, Germany.
12,122. Knife Sharpener, F. Tschofen, London.
12,123. Training Hops and other Plants, J. Watkins, London.
12,124. Divers' Boots, W. R. Foster and R. Fox, London.
12,125. Divers' Air-pumps, W. R. Foster and R. Fox, London.
12,126. Inflating Pneumatic Tires, S. Spencer, London.
12,127. Elevators, J. W. Naylor, London.
12,128. Spittoons, W. Jucker, London.
12,129. Boot Tag or Lift, R. Haddan.—(*P. Förck, jun., Germany.*)
12,130. Holding Photographic Films, A. C. Kitz, London.
12,131. Electric Brake Mechanism, L. E. Freedley, London.
12,132. Riveting Machines, B. L. D'Aubigné, London.
12,133. Picture Suspender, W. Beeston, London.
12,134. Deodorising or Disinfecting Apparatus, W. Gedge, London.
12,135. Guard for Points of Bonnet Pins, R. Wilkins, London.
12,136. Stencil and other Sheets, E. de Zuccato, London.
12,137. Walking-stick and Lamp, H. Newbold, London.
12,138. Cigarette Makers, W. D. and H. O. Wills.—(*D. B. Strouse, United States.*)

*23rd June*, 1894.

12,139. Playing Board, F. Allen and F. Waldock, Hampton.
12,140. Electric Igniters, A. A. C. Swinton, London.
12,141. Cellar and other Guards, J. J. Adkins, London.
12,142. Curling and Rounding Hats, F. Elliott, Atherstone.
12,143. Book Protector, J. Elliott and A. E. Waite, London.
12,144. Laundry Blue, E. J. Surl and H. Chancellor, Bristol.
12,145. Colouring Matters, I. and I. Levinstein and Co., Ld., Manchester.
12,146. Street and other Lamps, J. C. Bell, London.
12,147. Electrical Gripper Bar, W. B. Silverlock, London.
12,148. Money or other Case, E. Harrison, London.
12,149. Case for Money and Cards, &c., E. Harrison, London.
12,150. Valves for Pneumatic Tires, W. Phillips, Leicester.
12,151. Lever Switch, C. Langstone and B. Young, Birmingham.
12,152. Indicating and Checking Apparatus, E. Parr, London.
12,153. Securing Window Sashes, G. Wheeldon, son, Derby.
12,154. Accordeons or Melodeons, J. P. Browne, Glasgow.
12,155. Seats of Cycle Saddles, T. Webb, Birmingham.
12,156. Cycle Driving Gear, F. Smart, Manchester
12,157. Apparatus for Advertising on Wheels, J. Leadbeater, Leeds.
12,158. Perforated Music Sheets, &c., W. G. Griffith, Manchester.
12,159. Woven Fabric, J. Bright and Brothers and W. Briggs, Manchester.
12,160. Driving Gear of Cycles, J. H. Baynes and J. O. M. Parker, Manchester.
12,161. Hair Waving Appliances, W. L. B. Binde, London.
12,162. Fixing Photographic Cameras, F. W. Turner, Bury St. Edmunds.
12,163. Camera Stands, W. J. Pickersgill and M. Hunter, Sunderland.
12,164. Trasparent Tympan, E. Lee, Leeds.
12,165. Automatically Holding Candles, J. Legge, Willenhall.
12,166. Vehicle Tires, J. Duncan and W. Whyte, Glasgow.
12,167. Preventing Ships Sinking, T. H. Watson, Newcastle-on-Tyne.
12,168. Oil Lamps and Fittings, W. Reynolds and C. H. Sherer, Coventry.
12,169. Fasteners for Ladies' Hats, C. Merington, Essex.
12,170. Two-speed Gearing for Bicycles, J. I. and W. F. Richards, Swansea.
12,171. Method for the Removal of Arsenic, &c., W. A. Jenkin, Spain.
12,172. Bicycles, G. B. Main, Glasgow,
12,173. Sliding Windows, J. Money, Glasgow.
12,174. Peptonised Extract of Malted Cereals, P. Maltine, Leicester.
12,175. Cranes for Ships, A. B. Brown, Glasgow.
12,176. Preparing Arsenic for Destroying Weeds, J. R. Carruthers, Glasgow.
12,177. Automatic Sluices, F. G. M. Stoney, Glasgow.
12,178. Binding Sheets of Music, D. Mitchell, Birmingham.
12,179. Refuse Furnaces, B. D. Healey, London
12,180. Wheels for Vehicles, W. H. Atwood and N. Smythe, Birmingham.
12,181. Apparatus for Soldering, R. E. B. Crompton, London.
12,182. Grinding or Polishing Tubes, J. McGhie, Glasgow.
12,183. Electrical Propulsion, J. E. Parker, United States.
12,184. Improving the Female Figure, H. J. Bildyard, London.
12,185. An Improved Stopper and Bottle, J. W. Alexander, London.
12,186. Seed Drills, A. J. Boult.—(*W. Hull, Canada.*)
12,187. Preserving Changeable Liquids, F. de Backer, Liverpool.
12,188. Teaching Models, Drawing, &c., C. Clark, Manchester.
12,189. Tandem Bicycles, P. Gill, Liverpool.
12,190. Circular Looms, R. Weiss, London.
12,191. Filling Bottles with Liquids, T. Roberts, Manchester.
12,192. Hypodermic Injection Syringes, F. de Backer, Liverpool.
12,193. Medals, Medallions, &c, H. Grueber, London.
12,194. Vermin Traps, J. Johnstone, London.
12,195. Bottling and Stoppering Liquids, T. Sutcliffe, London.
12,196. Brewing Beer, A. F. Spencer, London.
12,197. Moving Targets, G. T. Teasdale-Buckell and E. W. D. Cuming, London.
12,198. Treatment of Gonorrhea, W. H. Greer, London.
12,199. Stands for Bouquets and the like, J. Feaver, London.
12,200. Materials for Rims of Cycles, J. H. Barry, London.
12,201. Mills, R. Harris, United States.
12,202. Compensator for Railway Signal Wires, G. H. Phillips, London.
12,203. Railway Signalling Apparatus, W. Saunders, London.
12,204. Driving Mechanism for Machinery, F. H. Crafts, London.
12,205. Perpetual Calendar, H. L. Weed and E. Pittwood, London.
12,206. Liquid Cooling Apparatus, J. E. Bennett, London.
12,207. Releasing Tubes, R. Wootton and B Hewitt, Birmingham.
12,208. Manufacture of Machine Screws, R. J. Alpe, Birmingham.
12,209. Punching and Eyeletting Machine, A. Senior, London.
12,210. Gaiters, &c., J. Faulkner and W. J. Vann, Manchester.
12,211. Clocks, W. H. Alderson, Manchester.
12,212. Omnibus Starting Apparatus, A. D. Bowie, London.
12,213. Supporting Optical Instruments, J. Aitchison, London.
12,214. Colouring Matters, O. Imray.—(*The Society of Chemical Industry in Basle, Switzerland.*)
12,215. Drainage Traps for Steam Pipes, E. E. Gold, London.
12,216. Velocipedes, T. Ledward and E. H. Beckett, London.
12,217. Mirrors, The Hon. C. A. Parsons, J. B. Willis, and G. G. Stoney, London.
12,218. Manufacture of Cyanides, H. Y. Castner, London.
12,219. Manufacture of Cyanides, H. Y. Castner, London.
12,220. Bath for Infants, G. L. Lavington and E. A. Wright, London
12,221. Electrical Furnaces, P. M. Justice.—(*E. G. Acheson, United States.*)
12,222. Bells, C. H. Gerrard, London.
12,223. Boiler Furnaces, J. Y. Johnson.—(*J. P. Serve, France.*)
12,224. Steam Boilers, J. Y. Johnson.—(*J. P. Serve, France.*)
12,225. Storing and Delivering Coins, H. M. Field, London.
12,226. Cigar-cutters, E. Miller, London.
12,227. Dress Fastenings, I. K. Young, London.
12,228. Chaff Cutters, E. Scales, London.
12,229. Checking the Withdrawal of Liquids, J. Boden, London.
12,230. Collapsible Magic Lanterns, A. Wrench, London.
12,231. Machine for Cutting Boards, J. C. Roberts, London.
12,232. Door-closing Devices, G. F. Redfern.—(*J. Stenbäck, Russia.*)
12,233. Non-slippery Pavements, A. J. B. Ward, London.
12,234. Bathing the Legs of Animals, H. M. Christopher, London.
12,235. Coverings for Bottles, H. Luyken and the Thompson and Norris Manufacturing Company, Ld., London.

12,236. Inkstands, H. H. Lake.—(*Hillgren and Company, Switzerland.*)
12,237. Ordnance, B. H. Thwaite, London.
12,238. Automatic Fire Alarms, H. H. Lake.—(*A. T. Wall and G. A. Wall, United States.*)
12,239. Leather and Canvas Bags, &c., H. H. Phillpot and J. Bathurst, London.

*25th June*, 1894.

12,240. Securing Buttons to Boots, C. Nicholls, Birmingham.
12,241. Electro-magnetic Traction, J. Perry and T. Tomlinson, London.
12,242. Clutches and the like, R. Harrington, Wolverhampton.
12,243. Wheel Hubs for Cycles, &c., I. Whitehouse, Birmingham.
12,244. Cycle Treadles, D. Spink, Dover.
12,245. Apparatus for Preventing the Abstraction of Letters from Boxes, C. T. and T. E. Gambrell and H. Headland, London.
12,246. Weaving Double-pile Fabrics, J. Clough and J. Park, London.
12,247. Cycle Gearing, B. Carreg, Liverpool.
12,248. Machine for Cleaning Fur, H. Beech, Manchester.
12,249. Key Sticks for Tip Carts, J. Trimmer, Southampton.
12,250. Bar Bells and Indian Clubs, A. Sturrock, Dundee.
12,251. Kites, B. F. S. Baden-Powell, London.
12,252. Oil Lamp, E. T. Daniels and S. W. Burton, London.
12,253. Tablet Detector, H. Powis and G. Evans, Shrewsbury.
12,254. Moustache Guards, D. H. Croll and C. Grant, Watford.
12,255. Railway Buffers, &c., T. and W. Latham, Sheffield.
12,256. Kitchen Safe or Cabinet, &c , J. H. Keys, London.
12,257. Pneumatic Tires of Bicycles, W. H. Sewell, Glasgow.
12,258. Stud for Wearing Apparel, G. T. Jones, Glamorgan.
12,259. Tandem Safety Bicycles, R. Kendrick, Birmingham.
12,260. Bicycle for Road or Water, W. Wagstaff, Farnworth.
12,261. Bicycles, W. H. Hockley, Birmingham.
12,262. Coal Vase Lid or Door, W. F. Bradbury, Birmingham.
12,263. Socketted Drain Pipes, J. Coulthurst, Manchester.
12,264. Cultivating, &c., the Land, J. E. Steevenson, Nottingham.
12,265. Single-speed Motion for Mules, W. Hurst, Bolton.
12,266. Taps, F. G. Fender, London.
12,267. Compound for Waterproofing Boots, W. J. Birnie, Bournemouth.
12,268. Syphon Flush Cistern, W. G. Jenkinson and T. Cartwright, Sheffield.
12,269. Photography, A. B. Chatwood, London.
12,270. Metal Tubes, R. Wooton and L. W. Goold, Birmingham.
12,271. Gas Engines with Slide Valves, W. J. Whitely, Birmingham.
12,272. Boxes for Millinery, J. H. Duffell, Birmingham.
12,273. Sinking Shafts, &c., G. C. Downing.—(*F. H. Poetsch, Germany.*)
12,274. Portable Air - propeller, L. G. and P. Chinnery, London.
12,275. Hydrocarbon Lamps, M. Dietmar, London.
12,276. Sheet-metal Mantels, J. Groves, London.
12,277. Consuming Smoke, A. J. Boult.—(*L. Hallbauer, United States.*)
12,278. Fastening Device for Clothing, E. Vollmer, Liverpool.
12,279. Tins for Printers' Inks, M. J. Smyth, Liverpool.
12,280. Friction Clutches, W. H. Cranstone and W. R. Hay, London.
12,281. Trimming of Wall Papers, W. Canning, Birmingham.
12,282. Cycle Stand, H. W. Holt and the Nimrod Cycle Company, London.
12,283. Block System for Electric Railways, E. Langen, London.
12,284. Securing Blind Cords, E. A. Jeffreys, A. H. Johnston, and A. K. Rotherham, London.
12,285. Dental Mirrors, F. H. Nalder, C. W. S. Crawley, and A. Soames, London.
12,286. Dies for Moulding, &c , Clay, D. Lewis, London.
12,287. Tube Expanders, W. Cross.—(*I. Allworthy, France.*)
12,288. Bending Metal Plates, F. Friedenthal, London.
12,289. Removing Fibre from Cotton Seed, R. Silcock, London.
12,290. Gripping Devices, T. Jenner, London.
12,291. Fire-places for Kilns, W. Hassall and H. W. Sansom, London.
12,292. Flying Machines, W. C. Sly, London.
12,293. Table Knives, J. Delaire, London.
12,294. Magazine, &c., Cameras, E. H. M. Seymour, London.
12,295. Condensing Alcoholic Vapours, P. C. Vivien, London.
12,296. Umbrella and Cane Stand, J. Funt, London.
12,297. Hair Brushes, L. W. Todd, London.
12,298. Plough Shares, J. H. Howard, London.
12,299. New Manufacture of Paint, A. J. Protheroe, London.
12,300. Coat Retainer, R. H. Wall, London.
12,301. Hair Frames, F. W. Kuschmann, London.
12,302. Moistening Labels, A. Rosenberg and J. Olfen, London.
12,303. Printing Fabrics, H. H. Lake.—(*La Société Bonnet, Ramel, Savigny, Giraud, and Marnas, France.*)
12,304. Telephone Systems, H. N. Frenay-Olyff, London.
12,305. Furniture Polish, A. P. Horn, London.
12,306. Foot - warmer Device, R. H. Thielemann, London.
12,307. Drawing Beer from Casks, T. W. Thorpe and W. H. Thomas, London.

*26th June*, 1894.

12,308. Governor for Motors, J. E. Greenhill and W. Fitch, London.
12,309. Distance - measuring Instruments, J. H. Steward, London.
12,310. Last, J. W. Curtis, Leicester.
12,311. Water - waste Preventer, &c., A. Monk, London.
12,312. Child's Bicycle Seat, J. Yates and A. Yates, Leicester.
12,313. Arc Lamps, F. M. Lewis, Leeds.
12,314. Curling Irons, T. Warsop, Nottingham.
12,315. Construction of Steam Vessels, R. Clegg, Halifax.
12,316. Sewing Machine Reel Carriers, D. Flanagan, Halifax.
12,317. Traction Engines, W. Sandeman, jun.—(*J. R. Greenwood, Argentine Republic.*)
12,318. Screw-down Taps or Cocks, W. H. Foster, Halifax.
12,319. Ventilating Apparatus, J. Evans, C. Harris, and T. F. Evans, Manchester.
12,320. Cover for Cooking Utensils, A. O. Morley, Birmingham.
12 321. Sewer Gas Taps, F. Parkin, London.
12,322. Spyhon Flushing Cisterns, W. Rodgers, Sheffield.
12,323. Bearing for Revolving Shafts, W. H. Baines, Sheffield.
12,324. Multiple Drilling Machines, G. W. Hawksley, Sheffield.
12,325. Sole for Boots and Shoes, D. G. Thomas, Glasgow.
12,326. Rubber Cushion or Buffer, J. MacDonald, Glasgow.
12.327. Air Pump and Bicycle Rest, G. F. Benson, Belfast.
12,328. Heating Furnaces for Ironworks, J. Brookes, Staffordshire.
12,329. Recording Quantities of Liquids, H. H. S. Pearse, London.
12,330. Clips, W. C. Butler, Edinburgh.
12,331. Mud Guard, W. T. Fuller, Bedford.
12,332. Musical Instruments, G. Ingram, London.
12,333. Hangers for Waist Bands, T. Davies, Pembroke Dock.
12,334. Valves, T. Thorp and T. G. Marsh, Manchester.
12,335 Shuttle-boxes of Looms, W. H. Hacking, Manchester.
12,336. Suspending Trousers, C. H. Spencer, Manchester.
12,337. Brushing Carpets, C. S. Chaffee, A. S. Hoffman, and F. A. Green, London.
12 338. Street-watering Vehicle, W. H. Miller, London.
12,339. Flap for Carriage Axles, G. Wilkes, Southampton.
12,340. Gear Cases for Bicycles, W. Brookes, Manchester.
12,341. Distillation of Zinc, H. T. Barnett, Westminster
12,342. Tap Holes of Casks, &c., C. J. Hill, Birmingham.
12,343. Clasp for Garments, S. Drew and R. Drew, Lancashire.
12,344. Delivering Boxes of Pins, A. G. Herbert, Birmingham.
12,345. System of Electrical Distribution, P. Wright, London.
12,346. Heating Liquids, W. P. Thompson.—(*J. Hutchinson, United States.*)
12,347. Flax Pulling Machines, W. P. Thompson.—(*L. P. Ordway, United States.*)
12,348. Portable Stands or Seats, J. R. Selbach, London.
12,349. Heating Metals, W. P. Thompson.—(*C. L. Coffin, United States.*)
12,350. Hydraulic Cement, W. Bruch, Liverpool.
12,351. Cotton Beaters, W. E. Heys.—(*A. Kirschner, France.*)
12,352. Appliance for Cleaning the Teeth, J. Weile, Glasgow.
12,353. Gas Stove, F. Littlewood, London.
12,354. Fanlight Fastenings, R. Hodges and S. Hill, London.
12,355. Calculating Clock or Dial, F. A. Göttsch, London.
12,356. Water Heaters or Boilers, C. T. Toulmin, London.
12,357. Strap Fasteners, F. L. Moore, London.
12,358. Skirt and Trousers, B. J. B. Mills.—(*B. Zeller and H. Crager, United States.*)
12,359. Pumps for Cycle Tires, W. F. Taylor and G. J. Philpott, Croydon.
12,360 Pumps for Cycle Tires, W. F. Taylor and G. J. Philpott, Croydon.
12,361. Pneumatic Pumps, W. F. Taylor and G. J. Philpott, Croydon.
12,362. Junction Ferrules for Piping, R. H. Attwater, London.
12,363 Ear Trumpets, J. Barr, London.
12,364. Boots, H. H. Lake.—(*E. F. Grandy, United States.*)
12,365 Post-marking Machines, H. H. Lake.—(*A. Leavitt, United States.*)
12,366. Boots, H. H. Lake.—(*J. H. Hannan, United States*)
12,367. Obtaining Glycerine, J. Van Ruymbeke and W. F. Jobbins, London.
12,368. Steam Boiler Furnaces, O. D. Orvis, London.
12,369. Elevator Controlling Devices, C. A. Harkness, London.
12,370. Vehicle Wheels, R. F. Hall, London.
12,371. Pneumatic Tire Detaching Tool, R. F. Hall, London.
12,372. Textile Machinery Aprons, J. H. Lorimer, London.
12,373. Wrought Metal Plough Share, J. Robinson, London.
12,374. Mudguard for Cycle Wheels, G. C. Topp, London.
12,375. Preventing Explosions in Boilers, G. L. Stocker, London.
12,376. Sash Fasteners, G. T. Lester, London.
12,377. Safe Petroleum Lighting, R. H. Courtenay, London.
12,378. Well Fishing Vessels, J. F. Green, London.
12,379. Water-tube Boilers, W. T. Whiteman.—(*J. W. Van Dyke, United States.*)
12,380. Water-tube Steam Boilers, L. D. Davis, London.
12,381. Metallic Powders, O. Imray.—(*J. Sachs, United States.*)
12,382. Metallic Powders, O. Imray.—(*J. Sachs, United Statee.*)
12,383. Glazing and Enamelling Bricks, M. Ahern, London.
12,384. Stannic Acid, I. A. F. Bang and M. F. A. Ruffin, London.
12,385. Keeping Tobacco, &c., Moist, F. Tschoffen, London.
12,386. Safety Envelopes, I. S. McGiehan, London.
12,387. Road Vehicles, H. Maasen, London.
12,388. Device for Locking Cycle Wheels, H. Badger, London.
12,389. Scales on Thermometers, E. M. V. Gibb and F. Cossor, London.
12,390. Feeding Device for Petroleum Engines, F. B. Poerschmann, London.
12,391. Connection of Bowls with Shafts, O. J. Ström, London.
12,392. Aerated Beverages, D. and J. B. Jackson, London.
12,393. Apparatus for Cleaning Boots, F. R. Smale, London.
12,394. Double-action for Velocipedes, E. Pasetti, London.
12,395. Legible Thermometer Scale, E. Jones, London.
12,396. Water and other Cocks, J. L. Dubois, London.
12,397. Gauging and Testing Rails, &c., P. Soulé, London.
12,398. Sprocket and other Wheels, W. A. Leggo, jun., London.
12,399. Safety Stirrup, A. Mihaloczy, London.
12,400. Lamp Regulator, F. Suisse and P. E. Hennequin, London.
12,401. Riding Carriages or Vehicles, H. L. Casse, London.
12,402. Fastening Handles on Brooms, C. Slater, London.
12,403. Chaff - cutting Machines, H. G. Waldock, London.
12,404. Commercial Travellers' Order-books, A. J. Tozer, London.
12,405. Advertising Device, W. G. Hawkins and A. R. Callcut, London.
12,406. Electric and other Motors, T. E. Waltham, London.
12,407. Cable Transmitters, H. Taylor, London.
12,408. Purification of Caramel, A. M. Clark.—(*La Société Gallet, Gibou, et Cie., France*)
12,409. Instantaneous Steam Generators, L. E. Solignac, London.
12,410. Filtering Materials, J. Wetter.—(*M. Weinrich, United States.*)
12,411. Lighting Tobacco Pipes, F. W. Schindler, London.
12,412. Knife Cleaner, A. N. Warburton, London.
12,413. Device for Cleaning Buttons, E. A. Meredith, London.
12,414. Machines for Washing Clothes, W. Berriman, London.
12,415. Oil and other Lamps, C. F. R. A. H. Bagot, London.
12,416. Covers for Tennis Balls, &c., H. Meenan, London.

*27th June*, 1894.

12,417. Pencil Sharpeners, &c., P. M. Gallagher, London.
12,418. Door and Window Frame, A. P. Sharp, Dublin.
12,419. Metal Clip for Roofs, Plant, Jackson, & Co., Birmingham.
12.420. Folding Telescope and Stand, T. Marshall, Surbiton.
12,421. Tachometer or Indicator, T. W. Harding, Leeds.
12,422. Levelling Instrument, F. J. Ryan and F. J. Ryan, jun , London.
12,423. Bottle Filling Machines, A. P. Blaxter, sen., London.
12,424. Knitting Machines, J. Schmitt and J. B. Coblenzer, London.
12,425. Refrigerator, H. Clarke, Burslem.
12,426 Teaching Children Arithmetic, R. G. Bennett, London.

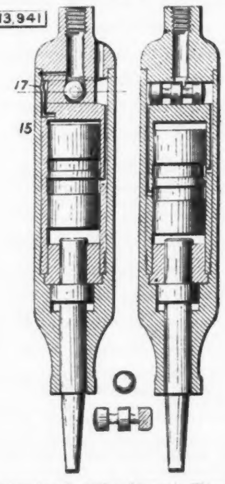
## SELECTED AMERICAN PATENTS.

*From the United States Patent Office Official Gazette.*

**513,941.** Pneumatic Tool, *C. B. King, Detroit, Mich. —Filed May 19th*, 1892.

*Claim.*—(1) The combination in a tool, of a cylindrical body portion having a shoulder at the top, a rotatorily adjustable sleeve upon the cylindrical body bearing at its upper end against the shoulder, said sleeve forming a controlling valve and a detachable clamping ring bearing against the lower end of the sleeve, substantially as described. (2) The combination in a tool, of a cylindrical body portion, having a cylinder and a valve chamber therein, the striker and valve, a nose-piece carrying the tool, and the sleeve rotatorily adjustable upon the cylindrical body, and forming the valve for controlling the blows of the tool, substantially as described. (3) In a tool of the kind described, the combination with the body, the reciprocating piston therein, the tool stock adapted to be struck by said piston, a piston on the tool stock, a cylinder in which said piston engages, having a passage connectiing the lower end thereof with the induction passage for the motive agent during the downward movement of the piston and having an opening at the upper end thereof above the piston, substantially as described. (4) In a tool of the kind described, the combination with the body portion, a detatchable nose-piece, of a spring latch, having a secured portion engaging into the nose-piece, and a pin passing through an aperture in the nose-piece and entering into the body, substantially as described. (5) In a tool of the kind described, the combination with a body and a sleeve movable thereon, of a spring catch for holding the sleeve in its adjusted position, consisting of a spring arm having the bent portion 15 forming the securing portion and a locking portion 17 adapted to engage in notches in the sleeve, substantially as described.

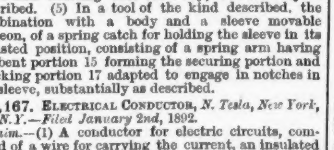
513,941



**514,167.** Electrical Conductor, *N. Tesla, New York, N.Y.—Filed January 2nd*, 1892.

*Claim.*—(1) A conductor for electric circuits, composed of a wire for carrying the current, an insulated coating or covering and a surrounding conducting sheath or screen divided into insulated sections, as set forth. (2) A conductor for electric circuits, composed of a wire for carrying the current, a coating or covering of insulating material and a surrounding conducting sheath or screen divided into insulated sections, the ends of which overlap, as set forth. (3) The combination of a wire or conductor for conveying electric currents, an insulated coating or covering therefor, a conducting sheath or screen surrounding the insulating coating and a connection between said sheathing and the ground containing a condenser of very small capacity or its equivalent.

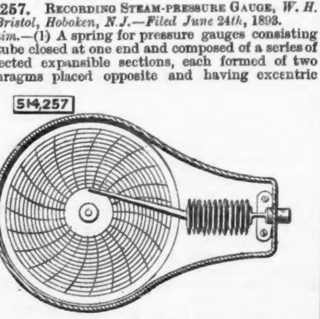
514,167



**514,257.** Recording Steam-pressure Gauge, *W. H. Bristol, Hoboken, N.J.—Filed June 24th*, 1893.

*Claim.*—(1) A spring for pressure gauges consisting of a tube closed at one end and composed of a series of connected expansible sections, each formed of two diaphragms placed opposite and having excentric openings, substantially as described. (2) A spring for pressure gauges, consisting of a tube closed at one end and composed of a series of connected corrugated diaphragms, each rendered more sensitive on one side of the axial line than on the other, substantially as described.

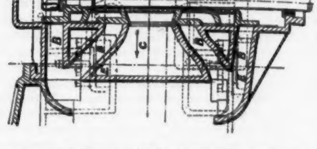
514,257



**514,333.** Steam Engine Attachment, *A. Normand, Havre, France.—Filed September 5th*, 1893.

*Claim.*—The combination with an engine cylinder having a valve chest, supply passages B for the cylinder, and an exhaust C, of independent blow-off valves arranged respectively at opposite end portions of the cylinder and communicating by passages E, which are independent of the passages B, with the cylinder, said valves being unseated by pressure in the cylinder and blowing off into the valve-chest, substantially as and for the purposes described.

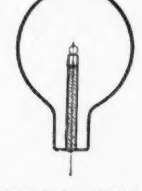
514,333



**540,170.** Incandescent Electric Light, *N. Tesla, New York, N.Y.—Filed January 2nd*, 1892.

*Claim.*—(1) In an incandescent electric lamp, the combination of an exhausted globe, a refractory light-giving body therein, a conductor leading into the globe and connected to or supporting the said body, and a conducting screen surrounding the said conductor, as set forth (2) In an incandescent electric lamp, the combination of an exhausted globe, a refractory light-giving body or button therein, a conducting support for said button within the globe, and a metallic tube surrounding or inclosing the said conductor up to the point of union with the button, as set forth. (3) In an incandescent electric lamp, the combination of an exhausted globe, a wire sealed therein, and coated with or embedded in a glass stem, a carbon stem united with the wire, a refractory conductor mounted on said stem, and a conducting tube or cylinder surrounding the wire and carbon stem, as and for the purpose set forth.

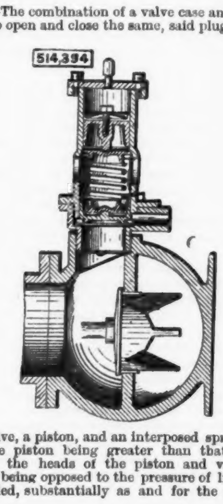
514,170



**514,394.** Device for Regulating and Relieving Pressure in Water Pipes, *H. G. van Everen and J. Henderson, Three Rivers, Mich.—Filed April 16th*, 1892.

*Claim.*—The combination of a valve case and a plug adapted to open and close the same, said plug consisting of a valve, a piston, and an interposed spring, the area of the piston being greater than that of the valve and the heads of the piston and valve respectively, being opposed to the pressure of liquid to be controlled, substantially as and for the purpose specified.

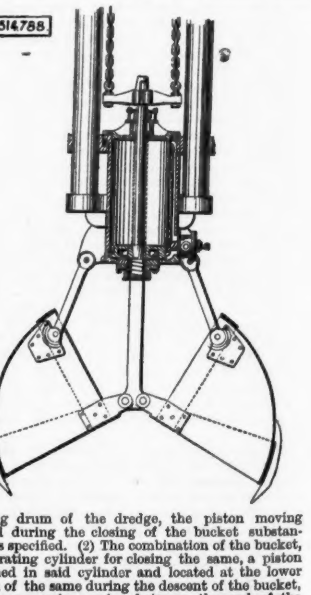
514,394



**514,788.** Dredging Bucket, *T. Symonds, Leominster, Mass.—Filed February 15th*, 1893.

*Claim.*—(1) The combination with the dredging bucket, of a cylinder, a piston contained therein, a piston-rod, a crosshead connected to the bucket, and hoisting chains extending from the crosshead to the winding drum of the dredge, the piston moving upward during the closing of the bucket substantially as specified. (2) The combination of the bucket, an operating cylinder for closing the same, a piston contained in said cylinder and located at the lower portion of the same during the descent of the bucket, and a compression spring between the end of the cylinder and said piston, substantially as and for the purpose set forth.

514788



## OIL ENGINES AT THE R.A.S.E. SHOW.

IN continuing our notice of the fixed engines which entered the consumption trials, we now reach the Hornsby-Akroyd engine which was next in order to that of Messrs. Fielding and Platt, which we described in our last issue. This engine, as most of our readers are aware, differs essentially from all the others which were tested, in that it employs no ignition tube or lamp for heating and ignition. It is the only engine which comes under Class 2 of the classification given on page 7 *ante*. The main features of the vaporiser, the lamp for heating it, the hand fan for supplying air to the lamp, and the cover to the vaporiser, may be gathered from the annexed sketches. The vaporiser is a small-necked bottle-shape extension of the cylinder. It contains a number of inwardly projecting longitudinal radial ribs. These serve as heat-receiving and heat-emitting masses and surfaces, upon which the oil used is vaporised and converted into a gas. For starting the engine the vaporiser marked V is heated by means of two lamps—as shown in the engraving in our impression of the 29th ult.—each one similar to that shown at L in the annexed section. These are rough, strong lamps, which with the supply of air from a fan at F, give a very powerful flame of high intensity. By this means the vaporiser is raised to a sufficiently high temperature to evaporate oil sent into the vaporiser by the hand working of the oil pump, and also to ignite the mixture of oil, gas, and air which is formed when the fly-wheel of the engine is turned two or three times by hand. When care was taken to make sure of this high temperature ignition of the air and gas mixture always took place with a few turns of the engine. Once started, the temperature necessary for vaporisation is maintained by the heat due to combustion, and that necessary for ignition has the same origin plus the rise in temperature due to the compression of the working mixture. The admission of the oil to the vaporiser from the pump is controlled firstly by the valve at N, and secondly by the valve above it, which is an overflow valve controlled by the governor, the latter acting by permitting the escape of the oil by an easier path than that into the vaporiser which it enters at H.

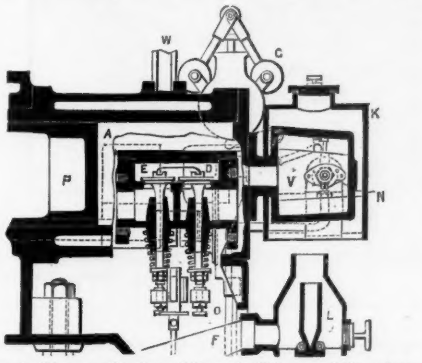


Fig. 1—Diagram Section of Hornsby Valves and Vaporiser

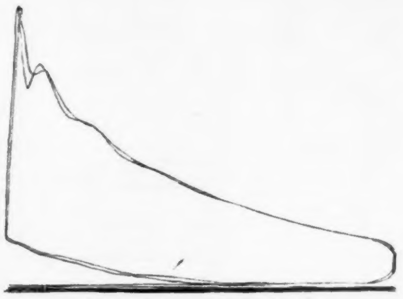

Fig. 4—Diagram Griffin Engine

The leading dimensions of this engine and the oil consumption were given at page 10 of our last issue, from which it will have been seen that the consumption on full load was such as to give satisfaction to the makers of the engine. On full load the working of the engine did credit to the system, and the conditions were, of course, the best possible for the operation of an engine in which it is necessary for the best working to run without any misses—in other words, to run with a regular load, so as to maintain with the greatest possible uniformity the proper internal temperature for vaporisation and for automatic or spontaneous ignition at the proper moment. A good idea of the arrangement of the oil pump, oil pipes, and connections, and of the fan and lamps, may be obtained by reference to the engraving on page 566 above mentioned. It will be seen from the sketch above, giving a transverse section of the vaporiser and oil valves, that the latter are contained in a small casting attached to the vaporiser by a flange at H. It is just outside the cover K, but in order to keep it at a uniform and moderate temperature a small supply of water is circulated through a jacket round the valve by means of a pipe J, and a delivery pipe J, connected to the delivery from the main cylinder jacket. The section shown above is taken partly along the axis of the cylinder and vaporiser, and partly through the valve-box; the air admission valve being shown at E and the exhaust valve at D. On the top of the cover which protects the vaporiser from cooling draughts are two lids, either or both of which may be removed if the vaporiser reaches too high a temperature. When running on half load the combustion in this engine was almost as perfect as when running on full load; but when running light this was not the case, and observation on this point is confirmed by the consumption of oil when running light. During the last-mentioned run of four hours, the engine took and fired a charge at every fourth stroke, there being practically no misses, yet the engine did not apparently increase in speed, and as far as is known no change was made either in the amount of compression or in the coating of the vaporiser. This light run was, in fact, a remarkable performance, and the temperature of the vaporiser was maintained automatically throughout, with the exception of one lighting up of the lamps and use of the fan. For this purpose, and in this respect, the use of an independent pump or fan has some advantages, as a flagging vaporiser and ignition surface, can be recuperated at any time during a run. It proved to be of great value in this case, and also during the half-power run. It is perhaps necessary to the Hornsby-Akroyd system, and we do not know that any objection can be urged to the use of the hand fan during the no-load run. Where an independent vaporiser is employed it is not necessary, and instead of using a combustible charge at every possible working stroke, only one now and then need be taken, and the consumption in this way may be very light. The same remark holds with regard to the half load, though of course to a lesser degree, but the independent lamp has to be fed. Messrs. Hornsby are to be congratulated upon the running of their engine; and although it was not the lowest in oil consumption, even when compared with an engine approaching its own power, it was shown to be a thoroughly practical engine, and one which could be depended upon to give excellent results in ordinarily careful hands.

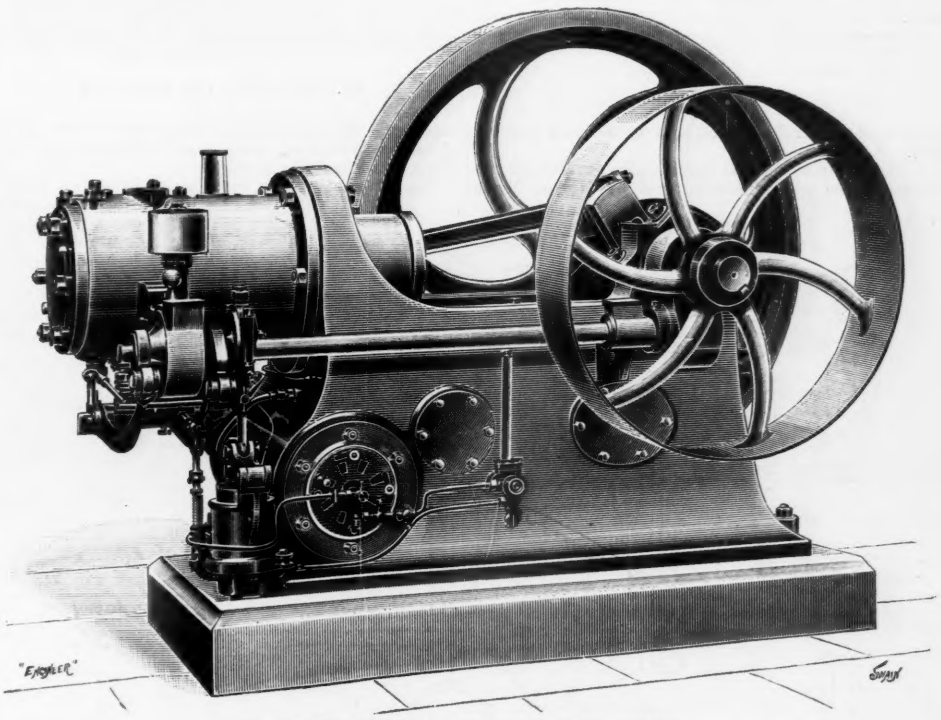

Fig. 3—SAMUELSON'S OIL ENGINE—GRIFFIN'S SYSTEM

The next engine in the order in the trial shed is that of Messrs. Samuelson and Co., which we illustrate on this page. This engine is made under the Griffin patents, and is one which recently gained the Vermiel Medal at a recent trial at Paris, carried out under the auspices of the French Government. Other English engines were present at this trial, but this one received the highest number of marks. At Cambridge it was the only engine which comes under Class 1 and Class 6. A perspective view taken from a photograph is given on this page, and details are given on this and on page 26. The spray-maker, by which the oil in a fine state of division is sent into the retort or heater—page 27—is attached at the end, and in the centre of the cover, carrying the air-admission plate, held in place by the butterfly nuts shown. At the opposite end of the same heater, which is surrounded by exhaust and air passages, is an adjustable air inlet valve adjusted by a handle and screw, as shown. The heater is of itself, in section, a corrugated tube, and its temperature after the engine has been started by means of a hand pump and ignited spray inside the heater is maintained at the necessary temperature for complete vaporisation by the exhaust gases on their passage to the atmosphere. The end of the heater which receives the spray is shown in the elevation of the engine, page 26, and this also shows the connection between the air pump—which can either be worked by a hand lever or by the excentric shown—and the oil supply within the tank formed in the frame of the engine. From the same view may be seen the attachment of the inlet and exhaust pipes which connect the far end of the heater with the valve case shown in detail on page 26. The end elevation of the engine also shows the connection by these pipes between heater and inlet and exhaust valve chest. The spray maker employed at the pump end of the heater or retort is of a simple form, and is somewhat like the diffuser form of spray maker adopted for the lamp for heating the ignition tube, as shown on page 27. This ignition tube heater may be at once described. It is almost the same, and the action is precisely that described in THE ENGINEER of the 2nd December, 1892. Oil is supplied by the pipe marked oil tube, air being admitted under pressure of about 12 lb. per square inch through the air tube shown. This air-jet blows the oil, which by capillarity finds its way between the two bent pins seen in elevation and by dotted lines in plan on page 27. A constant supply of oil is provided, and any excess over that necessary to maintain it at the proper level in the little tank supplying the capillary pins passes away down the oil overflow tube. This is one of the prettiest details in the engine, and it is rather curious that such a means of avoiding the use of oil jets with very fine holes and very fine adjustment is not employed for the main spray maker in this and other spray maker engines.

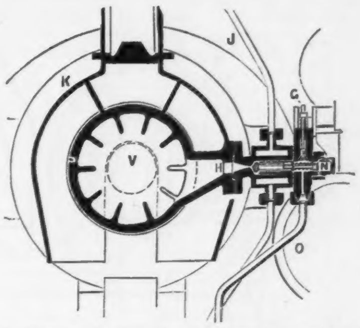

Fig. 2—Diagram Section, Hornsby Vaporiser and Oil Valves

The spray maker used for this purpose in the Griffin engine is shown in section at the left-hand corner of the spray maker engravings just referred to. The oil inlet is at the lower part of a casing containing a valve on the end of a piston of some length immediately below the words air inlet. This valve is ordinarily pushed upwards by a spring beneath it. Above it is an inlet for air under pressure, the inlet being controlled by the governor gear, and hit-and-miss arrangements which control the inlet valve. This air under pressure pushes the piston down, and at the same time some of it rushes through the horizontal jet piece, which by induction draws oil from the space in which the valve at the bottom of the valve stem dips. Oil and air are thus together blown from the double jet piece only when a working stroke has to be made. The inlet and exhaust valves are both operated by hit-and-miss knife edge pieces, controlled by the governor, and by the rocking levers shown in the end elevation, page 26. Thus the spray making, the exhaust, and the inlet, all are under the control of the governor, and the all or none system of governing is adopted.

At Cambridge this engine ran through the preliminary trials, but a hitch occurred when the engine was to be started for the consumption trials. Some time was expended in starting the engine, but it did not run as it had previously, and eventually it was found necessary to withdraw from the further trials and to ascertain the cause of the difficulty. Whatever this difficulty may have been, it was removed on the Friday morning, and as far as we know, the only change made was the insertion of a new ignition tube of greater length, after which the engine was kept running for some time, but not in competition. The diagram, Fig. 4, was taken at this time. The engine, as we have stated, had run through the long duration trials, but its combustion was not quite satisfactory, and on the third day was less so than it had been. It is probable that unsatisfactory ignition was the cause, as this would be reflected and magnified in an engine depending upon exhaust temperature for the classification of the oil vapour. The next engine was the Capitaine, but as it did not run in the consumption

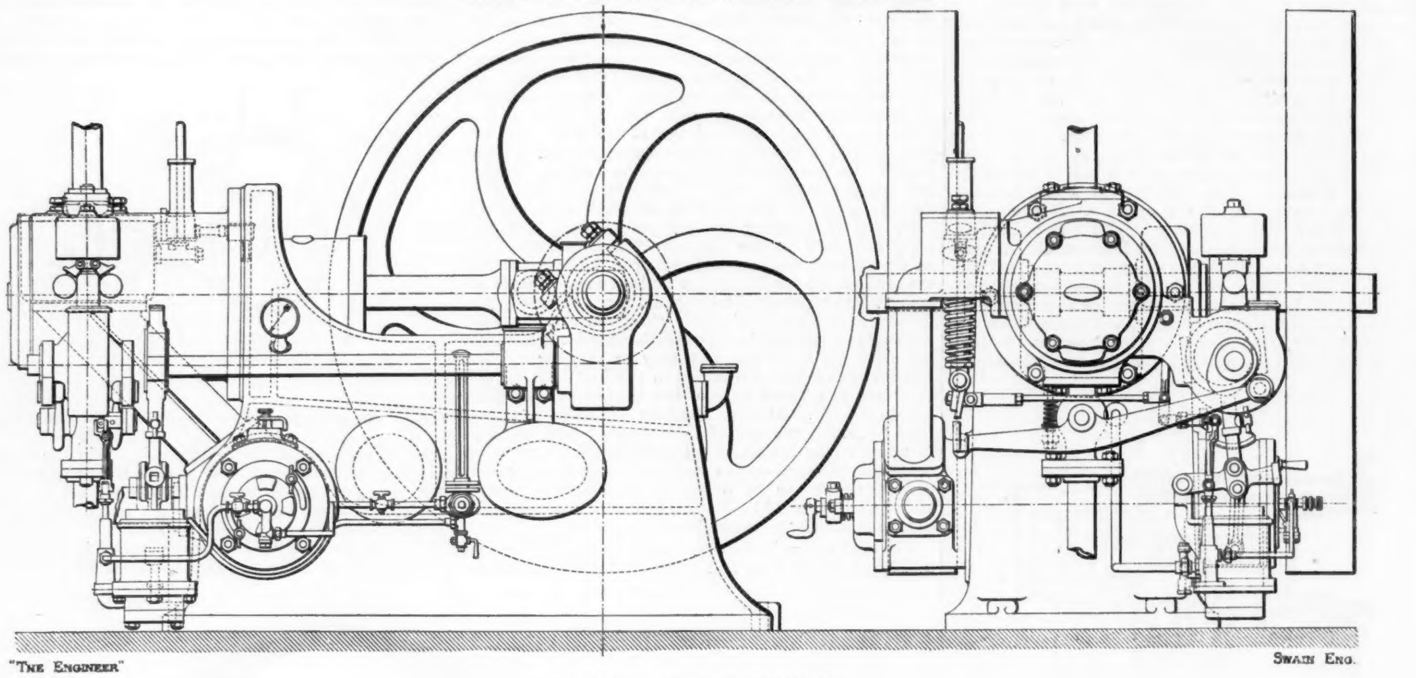

Fig. 5—SIDE AND END ELEVATION

trials we defer our description of it to our next impression.

We now come to the next engine which ran through the whole of the trials, namely, that by Messrs. Wells Brothers, made under Hamilton's patents. We are not yet in possession of a perspective view of this engine, but the accompanying engraving from an end view shows the arrangement of the vaporiser and valve gear, and the small engraving, Fig. 10, shows the arrangement of the vaporiser. The engine comes under classes four and six of our classification, the vaporiser being of the high temperature gasifying type.

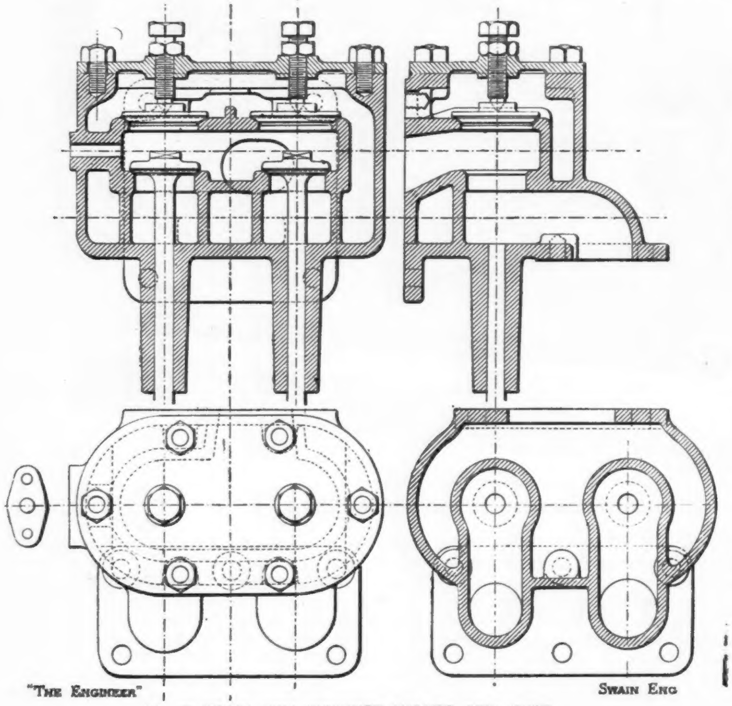

Fig. 6—INLET AND EXHAUST VALVES AND CASE

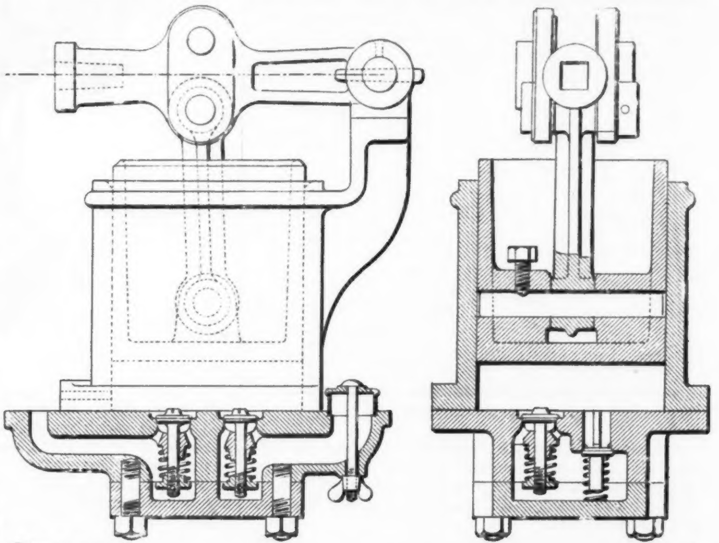

Fig. 7—AIR PUMP

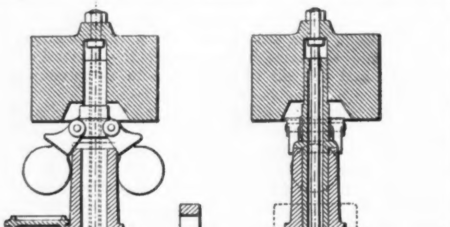

Fig. 8—GOVERNOR OF GRIFFIN OIL ENGINE

The air used is heated by being led through a passage round the combustion chamber. The valves are three in number, viz., an oil measuring and admission valve—Figs. 12 and 13—of the oscillating type, to which the oil flows by gravity; an admission valve for oil, vapour, and air; and an exhaust valve, the latter two being of the usual mushroom type. All these valves are operated by one lever and cam, a spring being used to keep the roller in contact with the cam as described hereafter.

The governing is effected by cutting out ignitions and holding the exhaust valve open. For this purpose a catch attached to a horizontal lever comes into engagement with a tooth on the valve operating lever when the latter has opened the exhaust valve, and thus the lever and all the valves remain at rest during one or more cycles, according to the work the engine is doing.

The horizontal lever above mentioned has at the opposite end to that at which the catch is fixed a hardened steel cam surface, which is struck by a similar surface on the crank arm which operates the oil-measuring valve. The action of this mechanism is to bring the catch opposite the tooth on the lever, and if the spring which acts on the horizontal lever is not strong enough to overcome the inertia of this lever, thus allowing the cam surfaces to separate, an engagement will take place, and there will be no following ignition.

The ignition is effected by a hot tube of durable metal, the tube being kept red hot by the burner that heats the vaporiser. This burner is of the regenerative kind, the waste products of combustion forming a jacket round the pipe which conveys the mixed oil and air to the burner. The air is supplied under pressure by an air pump, which can either be worked by hand or by the engine, and an air reservoir is used in connection with the delivery pipe to equalise the blast.

A very ingenious arrangement is adopted for working the air pump either by hand or by the engine, as required. An excentric on the side shaft has its strap pivoted to the lever which works the pump, the fulcrum of the lever being a pin in the side shaft bracket. When the pump is to be worked by hand this pin is removed, and the pin jointing the excentric strap to the lever now forms the fulcrum of the latter.

In general design the engine much resembles the Premier gas engine made by the same firm. In the trial shed it was known as the dark horse, for no one knew of it, and no wonder, when we are told that experiments in connection with it were only commenced about nine months ago.

Referring now to the engravings, the oil-supply pipe O leads from a tank at a higher level than the engine, and supplies oil to the burner by means of a connection P, having a cock for turning off the oil, and also an adjusting screw to regulate the feed of oil to the burner. The main cock M shuts off oil from the admission and measuring valve N, which consists of an oscillating plug having a recess in it, and also a port for the passage of some of the air supply. The oscillating plug is operated from the lever L, which also operates the admission valve A and exhaust valve E. The pipe Q allows the air to escape from the recess in the plug when a charge of oil enters,

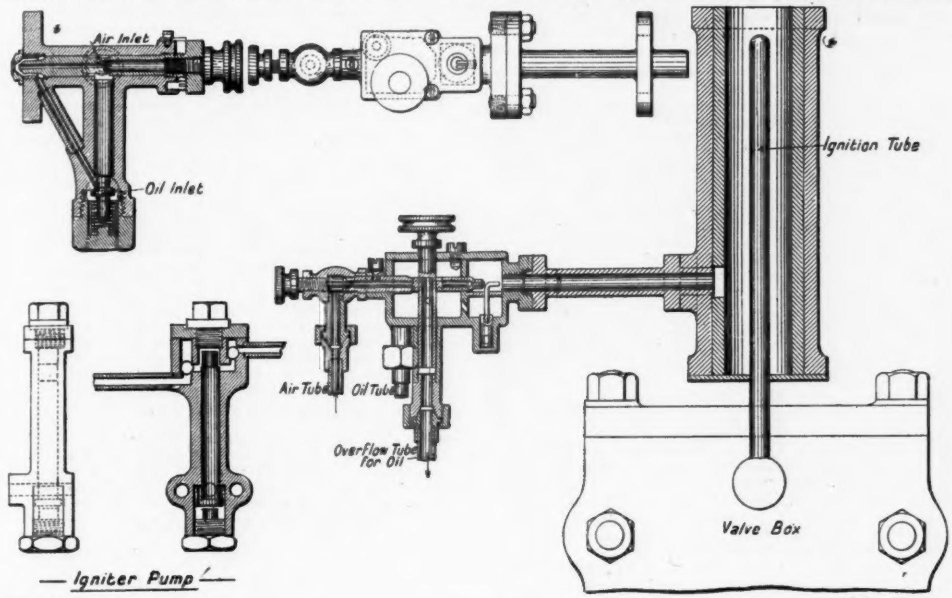
and when this is of glass, the ascent of each bubble shows when a charge of oil is taken.



"The Engineer" Swain Eng.

Fig. 10—GRIFFIN SPRAY MAKER, AND SPRAY BURNER FOR IGNITION TUBE

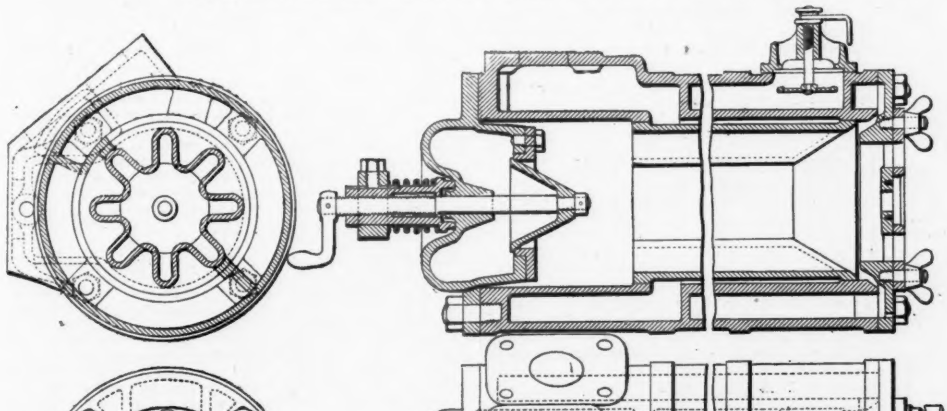


Fig. 10—GRIFFIN OIL ENGINE—VAPOUR HEATER AND EXHAUST AND CHARGING PASSAGES

When the plug is in the position shown on the engraving the recess is in the bottom side, and the oil flows out of it on to a plate inside the vaporiser V, which is simply the admission valve chamber. This chamber is in communication with an air passage around the combustion chamber, the water jacket being outside this passage. The oil falls on the plate T, and the air that enters through the left-hand part of the port F passes upward and through a port in the oscillating plug, and then down over the wetted surface of the plate T, shown in Fig. 13. The burner which heats the ignition tube I also heats the bottom of the vaporiser, and the waste products from its combustion are led back around the pipe conveying the oil and air to the mouth of the burner. The oil is thus vaporised by the lamp flame as above mentioned, and the air is also heated by the heat of the combustion chamber before it enters the vaporiser. In entering the latter, part of the air is diverted so as to sweep through the port in the plug above mentioned and over the surfaces wetted by the oil.

The governing is effected by bringing the whole valve motion to rest, the exhaust valve being full open, as shown in the engraving, the admission valve closed, and the recess in the plug towards the bottom. The governor mechanism is clearly shown. When starting, the products of the combustion of the lamp are passed into the air passage to heat it up, and this is done by turning the plug X, Fig. 12.

In the table we published last week we do not give the oil consumption of this engine running light, as we did not obtain it at the time of the trial. We are, however, informed that during the four hours the lamp used 2 lb. and the engine 6 lb., or a total for four hours of 8 lb. This gives for a consumption of 1·15 lb. per brake horse-power an equivalent of 1·74 brake horse-power for running the engine light. This is very low, and although we did not see the oil weighed, we must say that it is consistent with the running of the engine, which was remarkably regular, and the combustion good, the admissions of oil being practically a constant of one in eleven. The consumption of oil on the long duration tests was less than in the short runs, as might be expected, for in both cases the oil used while putting on the brake, &c., is booked against the engine, as it was with the others, and sometimes the brake was not quickly got on, so that the loss on this head was not inconsiderable in a trial of two hours.

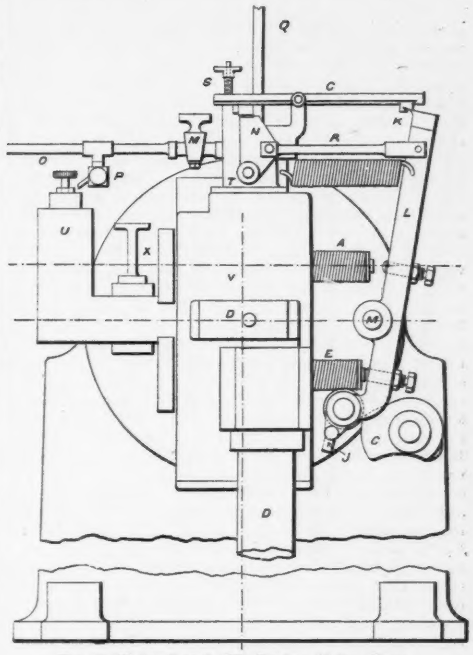

Fig. 12—Wells Bros.' Oil Engine Valve Gear

We have not mentioned that the engine ran five minutes over the two hours with the full load before the readings were taken. If duration of the trial be taken as 2 hours 5 minutes, the consumption per brake horse-power hour would be 1·10 not 1·15. The engine ran well, but at a slower speed than is desirable for most work. The combustion was generally complete, and the speed is said to have been reduced in consequence of the vibration, or we might almost say oscillation, of the ground during the first few days.

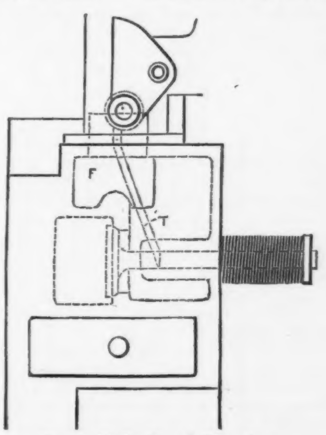

Fig. 13—Wells Bros.' Vaporiser

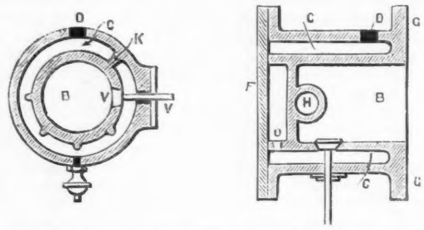
We now arrive at the last of the fixed engines which ran through the consumption trials, namely, the Trusty engine made under the Weyman-Knight patents by Messrs. Weyman and Hitchcock. This engine was of small size, a larger engine, which the makers intended to send, not being ready. It comes under classes 3 and 6 of the classification. Its construction is almost the same as that illustrated in The Engineer of the 4th December, 1891, which contains the results of a trial of the engine of that date. The engine tested at Cambridge gave higher brake horse-power with smaller diameter of cylinder and stroke, showing a considerable advance in this respect, although the Cambridge trials gave a less satisfactory result than was obtained in the trials reported in the above-mentioned impression. The vaporiser of this engine is fed by a small pump, which only acts when oil is required, and this varies in proportion to the load. The pump is worked by the hit-and-miss, controlled by the governor. The same hit-and-miss finger actuates the lever which opens the valve through which gas or vapour passes from the vaporiser to the combustion chamber. The vaporiser is roughly shown by the annexed diagram, in which B is the combustion chamber fixed to the end of the cylinder by the flanges G. Around the chamber B is an annular space formed by the chamber and a surrounding cylinder. This space C is not quite continuous, the diaphragm K filling the space between the inner and outer parts, and between the cover F and the flange G. Oil is admitted at D through a short glass tube drop by drop from the pump as required, air being at the same time admitted through the tube seen at the top of the cylinder. The section Fig. 14 is a vertical section at the vapour or gas valve, and Fig. 15 a horizontal mid-section showing the tube H, which is cast in and forms a chimney for the vaporiser heating lamp. The oil dropping on the upper surface of the inner cylinder below D is heated and evaporated as it passes round towards the bottom of the annular space and ultimately through the valve V into the combustion space, the passage of the gas and air being, however, by the form of the ribs and diaphragm shown, forced to pass the space O to reach the part containing the valve. It will thus be seen that the essentials of a really good vaporiser, namely, evaporating surface swept over by a current of heated air, are obtained in a simple way, while any excess of oil admitted for starting or during running may be, when necessary, drawn off by the cock shown in Fig. 14 above. This vaporiser is under complete control by means of the oil-drop system and vapour valve, with the result that, as was particularly noticed at Cambridge, the combustion was perfect during the whole of the long duration runs and during the consumption trials. The engine runs at a moderately high speed, which is necessary in a four-cycle engine if anything like regularity of turning with moderate rate of fly-wheel is to be attained. It is also important in engines of this cycle, for the work done by portable engines on farms, including the very irregular work of thrashing and sowing. For this reason it is to be regretted that a double-cylinder portable engine by the same makers was not ready for the trials. The governing of the engine is effected entirely with the oil pump and vapour valve, a jerk governor being used for the hit-and-miss finger. The gear is of the very simple kind, and there is no doubt that the time taken in starting, getting the brake on, and the oil used for these very short durations, tell heavily in such trials on so small an engine.



Figs. 14 and 5—Vaporiser of Trusty Oil Engine

The regularity of running of this engine was especially marked by the observers. The half-power run was made twice, in consequence of some uncertainty in the oil weighed out and back, and on the second run of two hours it was noted that during two consecutive quarter-hours the revolution counter gave exactly the same register; not one revolution difference in twice running through the two quarter-hours, or twice 4005 revolutions. On the two next quarter-hours there was a difference of only two revolutions. The oil consumption according to the second run on half-load 1·485 lb., including lamp, and 1·32 lb. without the lamp; but on the first run, the consumption was 1·129 lb. with the lamp, and 1 00 lb. without the lamp; and these figures, for the first half-load run, are so very nearly the same as those obtained on previous trials, that there seems to be very little doubt that the first oil weighings gave the correct total consumption, and not the second.

Before concluding this notice of the trials of the fixed engines on the consumption trials, reference should be made to the engine constructed by Messrs. Clayton, Shuttleworth, and Co., on the "Trusty" system. The engine was entered on behalf of the makers by Messrs. Weyman and Hitchcock, and it ran perfectly through the long-duration trials. As, however, it was fitted with a temporary lamp to show it at work without an air pump, it was decided to withdraw it from the consumption trials, as it was thought that the temporary character of the lamp would prejudice the engine in the eyes of the judges. Messrs. Clayton and Shuttleworth find that their special lamp without an air pump is sufficient when Royal Daylight and similar oils are used, but it was necessary to modify it to use Russoline. The engine itself, however, ran remarkably well, and combustion was perfect throughout the three long days. It ran at 252 revolutions per minute, and gave 6·83 brake horse-power.

With reference to the Britannia Company's engine particularly described last week, it should perhaps have been more explicitly stated that the diagram sketch of the vaporiser and connections was intended to show the principle of construction, and not the precise conformation given to the vaporiser and its connected passages. With regard to the running of the engine, it may be well to remark, though it is clear to those conversant with the subject, that the defects which we said on page 8 could obviously be remedied with ease, were due to the governing. But as we find that this was not understood, although the context showed it, we repeat that the engine would undoubtedly have run better with only one groove in feeding rod, and then govern by complete cut out; probably also by the exhaust valve. We may also repeat that the system on which the engine is constructed contains features of great importance, and it is, in fact, one of the best of all brought forward.

We shall return to the subject in another issue.

## MINERALS, RAILWAYS, AND ROADS OF HONDURAS.

The British Minister at Guatemala in a recent report on the economic condition of Honduras, the middle, and in size, the third State of Central America, observes: Honduras is essentially a mining country, and in the opinion of American experts and prospectors, the mineral wealth hidden beneath its serrated soil is enormous; yet on this so vital point, hardly any statistics are published. The country, considering its area, may be almost described as depopulated, and is seriously affected by the scarcity of labour, towards which the apathy and inherent aversion of the native is so great that unless recourse is had to foreign immigration on a large scale, the Republic is likely to remain, for years to come, in its present backward and undeveloped condition. Antimony, copper, gold, iron, lead, and silver are found in almost every department, and brown coal is said to be plentiful on the North coast. Recently, coal of a superior quality has been discovered by an Englishman residing in Sanpedro Sula. The coal, of a semi-anthracite character, is in a vein 5ft. thick, cropping to surface in close proximity to the Atlantic port of La Ceiba. This discovery will be of the greatest importance to the Republic, as the establishment of a coaling station in one of the central American Atlantic ports is one of the most urgent wants of steamers plying in that region. According to the mining code of Honduras—included in report—coal deposits are the exclusive property of the State, and cannot be denounced like other mineral-bearing deposits; but it is to be hoped that the Government will assist in securing some of the coal lands, and opening up the hidden treasure.

The hitherto non-success of many mining enterprises must be attributed chiefly to gross incompetence and often to dishonesty on the part of their managers. In addition, former administrations, in their anxiety to foster and extend the mining industry, made the mistake of conceding extensive tracts of land to applicants not in a position to turn their concessions to account, and often actuated by dishonest motives. The consequence was that so-called companies and syndicates acquired vast tracts of land, to the detriment of legitimate enterprise and honest prospectors. An idea of the worthlessness of these companies may be formed from the fact that while in the years 1887—9 no less than 800 mines were discovered, up till to-day hardly two or three of these claims have made a pretence of honest development.

The want of good internal communication is a serious drawback, which can only be removed by earnest and immediate endeavours of the Government to open up the remote districts of the country. No extension of the railway system has been made in the past year. The only line running is that from Puerto Cartér, one of the Atlantic ports, to San Pedro Sula, a distance of about 37 miles. A contract has been signed by Messrs. Valentine and Van Auken, American contractors, to extend this line to Amapala on the Pacific Coast, and thus connect the two oceans. If this contract be carried out, the Republic will benefit to a very great extent, as vast tracts of rich land and virgin forests will be opened out. If the great scheme of an inter-continental railway to connect New York and Patagonia is ever carried out, Honduras, with the whole of Central America, will reap considerable benefits, and be reckoned among the richest of the Latin-American States. Cart roads do not exist; traffic with the interior is chiefly carried on by pack mules; and in the winter time, *i.e.*, the rainy season, the condition of the bridle paths is such as to render them dangerous and often impassable for even these sure-footed animals.

The climate is good, and on the whole healthy, except on the coast, where the heat is intense, and malarial fevers, &c., prevalent. The mean reading of the thermometer at Tegucigalpa, the capital, situate about 3000ft. above the sea level, ranges from 64·4 deg.-68 deg. Fah. in December, to 73·4 deg. in April, May, June, July, and August. The great evil with which Honduras has to cope equally with the other Central American Republics is the frequency and evil of internecine strife, and their inevitable consequences, commercial and financial instability, which necessarily act as a powerful deterrent to any rapid advancement.

## INTERNAL NAVIGATION OF FRANCE.

French canal and river traffic experienced to a slight extent the general depression of French trade in 1893, tonnage on the former having decreased by 379,752 tons, or 2·29 per cent., and on the latter by 155,662 tons, or 1·77 per cent.; but these decreases were partly owing to increased railway competition. Goods rates were reduced in 1892 by 27 to 33 per cent. on slow, and by 50 per cent. on fast trains. According to a report of a committee of the Chamber of Deputies appointed to inquire into and report upon the subject of inland navigation, in 1881 the quantity of goods carried on canals and rivers was 19,740,000 tons, and on railways—exclusive of express goods—850,640,000 tons, the proportions being 17·88 and 82·12 per cent. respectively. In 1891 canal and river traffic had risen to 2,520,000 tons, and railway traffic to 99,600,000 tons, increases of 5,460,000 tons, or 27·66 per cent., and of 14,540,000 tons, or 17·02 per cent. respectively. The proportion of goods carried on canals and rivers rose to 20·19 per cent., while that on railways fell to 79·81 per cent. This increase of water-borne goods was due to legislation. In 1879 the length of French inland navigable waters was 7437 miles, but boats 120ft. long could not be taken through more than 906 miles of canal. A law was then enacted to the effect that all locks should be reduced to a uniform size, so as to allow the passage of 300 tons burden, 125ft. long, 16ft. 6in. wide, and 5ft. 10in. deep. Improvements were also made in the courses of the rivers Rhone, Saone, and Seine. The result was that in 1891 the length of navigable rivers had increased to 7670 miles, and the length open for boats 120ft. long to 2494¼ miles. A boat of 300 tons can now be hauled direct from Havre to the frontiers of Alsace, and from Dunkirk to Lyons, but there still remains much to be done to complete the network, large gaps existing between the Marne and Saone, Saone and Besançon, Rhone and Marseilles. In 1891 the number of boats was 15,925, the burden 2,996,583 tons, and the crews 40,468, of which half were men and the remainder women and children. The increases over 1881 were boats 1, tonnage 10, and crews 6 per cent. In addition to these boats, there are 691 steamers of 43,583 tons plying on the rivers. Many do a good business between Havre, Paris, and Lyons, and some constructed for sea voyages between Paris and French Atlantic ports, or Paris and London.

In 1880 all inland navigation dues in France were abolished, which gave an impetus to the carriage of heavy goods by water, but the necessity for some sort of tolls by water, leviable locally, for the use and repair of canals has lately been experienced, and an agitation for their establishment commenced. The cost of freight has varied since 1880 from ·2318d. to ·5408d., and is at present a little over ·1445d. per ton per mile. Most of the haulage on canals is done by horses, which in East France belong to the boat owners, and that on rivers by steam tugs. Where horses are not used, hauling is done by cattle hired from the farmers along the canals, the charge rising and falling as the demands of agricultural labour at harvest or sowing time are more or less pressing. The cost varies from ·04636d. to ·049272d. per ton per mile.

The drawbacks to the expansion of canal navigation are defective arrangements as to traction, and want and habit of organisation as regards freight. Vessels in some instances are owned by companies, and do a fair amount of continuous business, but half the boats are navigated by their owners, who live on board with their families, and whose usual career is—they start as boatman at monthly wages, and being thrifty generally save enough after years to buy a boat of 300 tons worth from £480 to £600, which they navigate themselves.

## LETTERS TO THE EDITOR.

(*We do not hold ourselves responsible for the opinions of our correspondents.*)

### CARNOT AND MODERN HEAT.

Sir,—Professor Alexander seems to have rather curious ideas concerning the value of time. I have not the least notion what he means about "a challenge" in my article of April 6th, nor why he thinks I must have been "put out" by his letter of May 11th, which in no way concerned me. He seems to be annoyed that I omitted to acknowledge receipt of his book, an omission which is doubtless a regrettable though a very frequent one, but I fear I scarcely realised that it was from him and not from his publishers that the copy came. He now adopts a curious method of admitting the futility of some of his mathematical processes, and challenges me to substantiate what I said in my article of June 29th, viz.: "That if we extrapolate quite illegitimately from Regnault's experiments, and assume that air has a perfectly constant specific heat, then it is a perfect gas, and its thermometric scale will agree with the absolute scale. But there needs no fireworks to tell us that."

Well, there was not intended to be the slightest difficulty about the meaning of this. A thing with constant specific heat has its intrinsic energy a linear function of its temperature, *i.e.*, proportional to the temperature reckoned from an appropriate zero; the absolute scale is a scale on which heat and temperature are proportional; hence allowing that a gas has no intrinsic energy at absolute zero, the statement is justified.

If there are any intermolecular forces the energy need not vanish at absolute zero, but it is just those intermolecular forces to which we must attribute observed variations in specific heat. Not indeed specific heat at constant volume, Regnault made no observations on that, nor could such observations throw any light on the subject of internal forces or absolute zero, but the ordinarily-measured specific heat after deducting the external work of expansion.

Putting the matter into symbols, the equations—

$$d\,Q = c\,d\,T + R\,\theta\frac{d\,v}{v} = T\,d\,\phi.$$

where $\theta$ is air-thermometer temperature, T is absolute temperature, and $c$ is specific heat at constant volume, do not, indeed, carry us much further, even though we are told that $c$ is constant, unless we know a relation between $\theta$ and T. But subdividing the expansion term into internal and external work, so as to write,

$$d\,Q = c'\,d\,T + R\,T\frac{d\,v}{v} = T\,d\,\phi,$$

and then being told that $c'$ is constant, we can proceed without difficulty.

Professor Alexander chooses to say now that his N was the specific heat at constant volume, the same as my $c$; but in that case his appeal to the experiments of Regnault was meaningless. Taking N as equal to $c'$, that is to say, giving to N the suitable interpretation—the only interpretation consistent with his assumed value for M—his proof, such as it is, holds. Whatever confusion there may be arises from his sentence, "But by Regnault's experiments it appears that for air N is constant." Everything depends on what you choose to assume constant; and since Regnault's experiments give one no right to assume *anything* strictly constant, the whole discussion is barren and a waste of time.

Given a perfect gas, its temperature scale is the same as the absolute scale, and there is no difficulty. Given an imperfect gas, there is an internal virial, and it is a matter of circumstance and convenience whether this be treated as a separate term in the general first law equation, or whether it be included in one or other of the coefficients. Experimentally it most naturally occurs along with the temperature coefficient, especially when small.

Liverpool, July 9th. Oliver J. Lodge.

Sir,—I have read and read again Dr. Lodge's two articles on "Entropy," and I confess that I am still quite in the dark as to what it is. I should not trouble the Professor, however, if Mr. Donkin had not written to ask Dr. Lodge for a practical example of it. That is to say, he wants Dr. Lodge to do something with an indicator card. From this I take it for granted that entropy is a thing which has something to do with the steam engine.

I have looked at Clausius; but I cannot make out from him what entropy is. Maxwell says, "We have next to consider the series of adiabatic lines as indicating a series of degrees of another property of the body expressed as a measurable quantity, such that when there is no communication of heat this quantity remains constant; but when heat enters or leaves the body, the quantity increases or diminishes. This is entropy."

I have not the least idea what "the degrees of a property" may mean. A body has either a property or it has not; but that property cannot be expressed in degrees. We may say that a body possesses the property of hardness; and we can legitimately qualify the hardness or express it in degrees, but not the property. Besides, the word "property" taken alone has in this case no definite meaning. Thus it is nonsense to write, "The body has a property." We ask at once, What property?

Turning to Dr. Lodge, I find on page 557 of The Engineer: "Entropy, a property characteristic of the state of a given quantity of matter, such that without a change in its value no heat can be imparted, and such that its change multiplied by temperature represents the amount of heat energy transferred." I do not know what these words mean, or rather, what Dr. Lodge intends them to mean. They seem to be nonsense. Suppose, for example, that

I have a pound of iron at 32 deg., am I to understand that some change must take place in some property of the iron before any heat can be imparted to it? Iron is heated every day. What brings about the change which alone enables it to receive the heat? Again, how are we to multiply a "change" by a temperature? In the "Arabian Nights" we hear of a man being changed into an ape, but it puzzles me to know how the change could be multiplied by the heat of the sun. Perhaps Dr. Lodge will give us a numerical example of this extraordinary arithmetical process. Thus, for instance, a pound of iron is raised in temperature 10 deg. Fah. In order, I suppose, to get the entropy, something has to be multiplied by 10 deg. Will Dr. Lodge say what?

In another place Dr. Lodge says that energy divided by temperature is entropy. Am I to conclude that the greater the temperature the less the entropy? Again, Dr. Lodge says on the same page, 557, that if a source of heat is applied to a gas at the same temperature as the gas, the gas may expand and do work without having either its temperature or its pressure raised. In this case the gas is certainly receiving heat. What is the change in the value of the entropy of the gas under the stated conditions? Lastly, is not Dr. Lodge mixing up temperature and heat?

To me it seems that entropy is neither more nor less than an algebraic expression—that it has no real existence. Dr. Lodge tries one definition after another. It is, he tells us, "a thing which falls in temperature down an adiabatic." I can understand a pound of iron or of air falling in temperature in such a way that a curve drawn through the plotted temperatures shall be an adiabatic, but I cannot understand an entropy as "a thing" which can be either hotter or cooler, any more than it can be heavier or lighter, stronger or weaker, at one time more than another.

I am not writing in any captious spirit. I do not want, like Professor Alexander, to "draw him.' I do want to know what the word entropy means. All that I can gather is what it is not. Thus I am told that it is "one factor in energy but not the whole." It would, I think, immensely simplify matters if Dr. Lodge and other writers like him would begin by stating precisely the sense in which they use words. It is with the greatest difficulty I can make out in some cases whether temperature or heat is meant. I know that to the non-scientific they are synonymous, but any approach to want of discrimination in their scientific use is most perplexing. Again, there are the words "work" and "energy." I am constantly puzzled to know in what sense Dr. Lodge uses them. Take, for instance, the sentence near the bottom of the middle column, page 557: "Suppose, for instance, that *no* energy is utilised, but that the whole of the heat supplied is allowed to fall in temperature by mere conduction out of a body at temperature $T_1$ into a body at $T_2$, the heat transferred being Q, and no work being done." I fail to see how it is possible for the body which receives heat not to have work done on it which will precisely equal the energy lost by the other body. There is no doubt a loss of availability; but that is not a real loss, but only a loss as compared with some third body at a different temperature; and if heat is a mode of motion, as Dr. Lodge says it is, "Energy in the form of the irregular motion called heat," then it is certain that the sum of the energy existing in the parts of any system cannot be altered by the interaction of the parts. What is needed here is a definite explanation of the meaning which Dr. Lodge attaches to "energy." Engineers usually define it as capacity for performing work. I do not think this is the sense in which Dr. Lodge uses it.

May I venture, in conclusion, to sum up my questions and ask Dr. Lodge to define in as few words as possible:—(1) What is the meaning of the word "entropy?" Is it, for example, "Loss of power to do work?" (2) Will he define the sense in which he uses energy? Is it, for example, power of doing work, and consequently the antithesis of energy? (3) What does he mean by heat; is it, for example, a mode of motion? I do not think it matters very much what the precise definition is, so long as we know exactly what it is each man has in his mind. If, for example, entropy means loss of power to overcome resistance, why not say so in these words? I can understand at once that low-pressure steam has more entropy than high-pressure steam. Of course the value of the knowledge of the meaning of entropy—when I have acquired it—I do not know; but I shall no doubt know when I read Dr. Lodge's reply to Mr. Donkin.

W. OLDKNOW.

Wolverhampton, July 8th.

### THE MAJESTIC AND MAGNIFICENT.

SIR,—Much interest will be felt in your description of these two ships, which I believe applies in its main features also to the Renown. Your information is probably derived from an inspection of the vessel, and is not official, so that even now we have not to thank the naval authorities for our tardy and partial enlightenment. There is probably no parallel, even in the history of public spending departments, for the course which the Admiralty have pursued in this matter. Ten new ships, costing nearly as many millions, are calmly declared to have been a mistake in their most important features, and another ten millions-worth are begun without any information being given as to the alterations proposed.

I observe with satisfaction that the course you have permitted me to urge in your columns for several years past has at length been adopted, and that the low belt with armour-deck above it has disappeared, it may be hoped, for ever. It is a remarkable fact that no one has ever been able to explain wherein the virtue of such a belt resided. Sir E. Reed, Sir N. Barnaby, and Mr. White are at one as to its uselessness to preserve stability, but yet the Admiralty have till now adhered with desperate tenacity, as usual, however, to suddenly abandon it, without giving any reason.

Your naval readers will be amused to learn that the arrangement by which the outer edge of the armour-deck stretches from stem to stern in a horizontal line "is a most invaluable feature of the new designs, and was never attempted before." They were probably under the impression, as I was, that it had been not only attempted, but achieved, in every protected cruiser that has ever been built. The new system is, in fact, the admission of the principle I have long contended for, viz., that as the armour-deck fitted in cruisers affords, weight for weight, a very much better protection to engines, magazines, and steering gear than the belt and deck hitherto fitted in battleships, and that as the armoured stability supposed to be furnished by a belt is a pure illusion, the armour-deck should be taken as the basis of protection in battleships as well as cruisers, and that what more is needed should be supplied independently. It need not be said that there is nothing new or original in this. It has been adopted in the three last completed of the six large Italian battleships, and in all the new French and American armoured cruisers. The only novelty is that, as in the Eclipse, the deck rises somewhat higher than heretofore, and that, judging from the increased displacement and much reduced armament, engine power, and coal supply as compared with the Italian ships, the side armour is thicker, ranging probably from 12in. to 15in.

It is satisfactory to note that one of the most vicious features of the Sovereign design to which I drew attention in your issue of January 30th, 1891, has been much modified in the new ships. The barbettes are within the citadel, and we thus no longer have the curious spectacle of an arrangement for bursting shells outside the ship in close proximity to one for ensuring their bursting inside. Above the citadel, however, the design is the same, and the barbette guns are still apparently to be carried so low that they are liable to be put out of action by the blowing up of the deck, while they cannot be fired ahead or astern. As evidence of the latter, I believe in none of the Sovereign class has it ever been attempted to fire the heavy guns without elevation within 70 deg. of the keel line. It is true we were told that the forward guns of the Majestic were to be 4ft. higher than in the Sovereign, but it was also stated to be the freeboard, not the barbette alone, which was to be thus raised. The immense superiority of the Admirals in this respect is clearly shown in the drawings illustrating your description.

The new arrangement of side-armour saves the designers from committal to the singular principle, which all evidence contradicts, that while 18in. armour is necessary from the water-line to 3ft. above it, from that point up to 9ft. all risks are sufficiently met by 4in. plating; but we are still apparently to believe that the crowded main deck, with its funnels, communications, and air-shafts, needs no armour at all, except round the guns, and that shells can burst with impunity beneath the upper-deck battery. In the French Brennus, launched three years ago, the upper-deck guns are in armoured turrets, mounted above an armoured side. Ten years hence we may hope to see British ships similarly protected. On the whole, however, the Majestic may be pronounced a decided improvement upon the Sovereign, except in the fact that while the displacement is increased, the coal supply remains the same.

One other question arises. The Majestic, you inform your readers, is to have a 4in. armour-deck reinforced by an armoured side. The Powerful, produced at the same time by the same designers, is, we are told, to have an 8in. deck, and no side-armour. The natural inference is that the Powerful is a battleship which has to meet ships with such enormously heavy guns that side-armour is useless. If the Powerful were a cruiser, intended to engage cruisers with numerous and comparatively light armaments, she would surely have been given a thinner deck and some side plating.

G. W. COBB.

Brecon, July 10th.

### TO ADVERTISERS.

SIR,—Will you kindly grant me space to vent a little grumble at the indifference shown by advertisers to applicants for such appointments as managers, foremen, and draughtsmen, especially the last. Advertisements continually appear inviting applications for this or that post. Men apply and patiently wait week after week without hearing aught further of the matter. To those out of employ, and with little or no means, and those having families dependent on them, this waiting becomes a serious consideration. Would it not be as well if advertisers included in their invitation to applicants for minor posts something after the style of "No reply by . . . Negative;" or, in the case of managers and higher positions, to notify immediately the selection is made that the "Vacancy advertised . . is now filled." Such a system as that suggested would be a relief to many who are waiting and watching hopefully for some response to their communications. If one's application be not entertained, it is some consolation to learn definitely and early that it is so. The trouble and cost involved in a general notification would be trifling indeed. We all know that to reply to each individual would be tedious and costly, and scarcely to be expected, especially at this time when advertisers are likely to be inundated with applications, but a general notice in your columns would be the means of setting many a mind at rest.

I have long been puzzled to understand why so many advertisers hide their identities under a *nom de plume* or Box No. Firms of repute rarely follow this rule. What is to be gained from its adoption is not very clear, unless it be to prevent undesirable personal application. That, however, could be easily avoided by distinctly specifying that applications be by letter only. Under the present system applicants have not the remotest idea of the destination of their communications. It is scarcely reasonable to expect a man to give such full particulars as advertisers ask for, and to furnish testimonials and references without knowing with whom he is communicating.

Again, as to the vagueness of some advertisements. Frequently one will be found to read something after this style:—"Wanted, a works manager for general engineering works. State age, experience, references, and salary required, to Box No. ——." How is it possible from such data to state a salary if the applicants be unacquainted with the name of the firm or establishment? The works may employ fifty men or 500 men. Perhaps the applicants, if any there be, will state a sum out of all proportion for a works of fifty men and sadly incommensurate for one of 500 men. If they be in doubt, and write asking for further information, the chances are that their letters are consigned to the waste basket or the boiler furnaces.

Now those referred to above are supposed to be men of intelligence and education, and if not gentlemen born, to be of gentlemanly demeanour, and as such they are entitled to some semblance of courtesy.

Surely the age of chivalry is not so far past that it will be deemed treasonable to ask *bonâ fide* advertisers to adopt in some degree the form I have suggested, presuming always that many will continue to hide under the objectionable *nom de plume*, or Box No. ——.

ONE OF THE APPLICANTS.

Newcastle-on-Tyne, July 19th.

### ENGINEERING AS A PROFESSION.

SIR,—I regret that I have been unable to follow up all the correspondence upon this subject. Among the letters I have seen I have only noticed two remarks upon the value of civil engineering as a profession. "Pater's" allusion to an individual's "one day's experience upon an iron bridge erected over a rapid stream" shows that one man entered this profession with no more aptitude for it than that possessed by the medical student who had to resign because he could not stand the dissecting-room. "Stud. Inst. C.E." shows that there is a man who can gather some of the harvest which is still to the hand of those engineers who can gather it. Of course it cannot be gathered by those who are "more fitted to be tailors," or by him who "only possesses the simian propensity to imitate what he sees."

When a large public work is commenced, one sees a variety of men come on the ground. I will say nothing of the chief engineer and his immediate subordinates; their positions speak for themselves. But I wish to call attention to the numerous young gentlemen who may generally be distinguished by their Norfolk jackets, pretty caps, and stockings of wonderfully variegated pattern. A few of these prove their ability and energy, and that, wherever engineers are required, they will get on. The majority remaining appeared to have obtained their position through "canvassing and influence," and, when once they have mastered the slight intricacies of the level and theodolite, seem as though they intend to devote the remainder of their days to swaggering around with these instruments, putting in pegs for the navvy ganger, who is generally a born engineer saving the education, to work to. I contend that, as long as such young men as these are permitted to dub themselves engineers, this profession can never take the exclusive standing accorded to, say, the medical or legal profession. I contend that it is these engineers' hacks who are chiefly responsible for raising the bitter cry for employment, and swelling the ranks of the hundreds who clamour for every appointment vacant, and bring the profession into disrepute.

A.M.I.C.E.

### INDIAN RAILWAY CONTRACTS.

SIR,—The answer of the India-office to Sir A. Hickman, M.P., has been read out here with the most profound astonishment. Sir A. Hickman charged the India-office with wishing or intending to order certain material abroad, because it could be obtained 25 per cent. cheaper than in England, and the India-office actually defended themselves from this imputation as from a crime, instead of replying that Sir A. Hickman had overlooked the fact that they were not British funds in question, that in the adjustment of accounts England does nothing for India, but rather drives a hard bargain, and that simple honesty demanded the purchase of the material in the best market. They might also have pointed out that Parliament takes the greatest interest in the welfare of the poor Indian when it is a case of making factory laws for his protection, and that certainly such a benevolent interest would not approve of the purchase in the dearest market, especially in the present critical state of Indian finances. I forget just how it was shown that the exclusion of cotton goods from the tariff was to the advantage of the poor Indian.

Have the English people any conscience, and are they content to be accused of the vilest hypocrisy in pretending to govern India for the good of the people, and in not having anything to do with their financial arrangements, while a representative of any British trade interest can have these arrangements upset—to suit his book—as a matter of course? Be at least honest and say, "Yes, we just govern India for what we can get out of it, and the interests of any tinker in England must stand before those of the people of India."

AN INDIAN ENGINEER.

Calcutta, June 18th.

### VACUUM BRAKES.

SIR,—In a recent trial at Swansea, arising out of the accident on the Taff Vale Railway near Llantrissant on the 12th August, 1893, the question was raised as to whether the driver of the train was guilty of negligence in not applying the continuous brake, but allowing his train to run on unchecked with the front van off the rails for more than a quarter of a mile, without even communicating with the guards, who were absolutely ignorant of anything amiss till the moment before their van at the centre of the train toppled over the bank. Into the merits of the case I will not enter, but I wish to refer to the evidence of the driver, who stated that he was afraid to put on the brake, as it would have checked his engine as well as the train, and caused telescoping, so he contented himself with putting on and shutting off steam alternately, with a view, as he said, to straighten the coach until the couplings snapped, and the brakes went on automatically, pulling up the engine which had been going at thirty miles an hour in a distance of 60 or 70 yards.

Now, if the driver was justified in his fears, it seems quite evident that the continuous brake as fitted on the Taff Vale Railway is of very little use, as it cannot be used on occasions when if it could be trusted it would be of the utmost value, and the simplest method of rendering it useful seems to be that the brake should be wholly disconnected from the engine wheels, and only operate on those of the coaches and brake vans, while the engine should have a perfectly independent brake. I do not know whether the system on the Taff Vale Railway is the same as that on other lines, or if it is in accordance with the regulations of the Board of Trade; but if it is, then it is manifest that a modification should be made in those regulations, and the brakes so fitted as to allow of their being used if necessary without checking the engine.

London, July 7th. W. P. THOMAS.

### OIL ENGINE TRIALS AT CAMBRIDGE.

SIR,—We strongly disapprove of the exclusion of the engineer Press representatives from the engine shed. Being informed that only the expert and one attendant could be present, no other representative of our firm attended, although we very much wished to see the test. We cheerfully submitted to our exclusion, as the space was limited, and we inferred the Press representatives would be present. We were much surprised to hear that eight or ten persons from one competing firm were allowed to be present in the shed during trials. At any future trials we should stipulate that all are treated alike, and that the Press representatives are present, or we certainly would not compete. It is important that we know the results promptly, and not wait months to get the information through the "Society's Journal." Had your representative been present we should have immediately received details which might be of considerable value to us and to the general public.

BRITANNIA COMPANY.

Colchester, July 5th.

### SEWAGE DISPOSAL.

SIR,—May I be allowed to point out, in connection with your kind notice of my work on "Sewage Disposal," that the northern outfall sewer is carried on an embankment for upwards of five miles, and cannot become surcharged, because of a storm overflow at the beginning of the sewer, and because of numerous openings in the crown of the sewer? The true discharging capacity can therefore be ascertained in wet weather. I am dealing with the subject in another way, and hope to raise a discussion on the matter next session at the Institution of Civil Engineers.

London, July 7th. N. SANTO CRIMP.

## SOCIETY OF ENGINEERS.

ON the 10th July, 1894, a visit was paid by the Society of Engineers to the Royal Small Arms Factory at Enfield Lock.

The following are the special operations carried out in the various sections of the factory:—

Smithery.—Barrel rolling, sword and sword bayonet rolling, stamping bodies, guards, bolts, &c., and forging various components.

Machine Gun Department.—Manufacture and repair of machine guns—Maxim, Nordenfelt, Gardner, and Gatling.

Barrel Room.—Barrel drilling, boring, turning, setting, rifling and chambering.

Tool Room.—Die sinking, manufacture of mills, drills, tools, and gauges generally.

Sword Department.—Machining and mounting swords, sword bayonets, and scabbards.

Large Room.—Noticeable for its size, containing 50,000 square feet and 1503 machines, requiring ten miles of belting. In this room the majority of the components in the rifle are machined, such as bolt, guard, sights, &c.

Stocking Department, woodwork.—Rough and finished turning stock, butts, and fore-ends, grooving fore-ends, and figure machining.

Screw Department.—Screw making by automatic machinery.

Grinding and Polishing Department.—Swords, sword bayonets, lance heads and shoes, and components of rifle generally.

Hardening and Tempering Department.—Swords, sword bayonets, springs, and general components.

Browning.—Sand blasting components before browning, browning barrels, bodies, &c.

Assembling Department.—Assembling actions and rifles.

The different buildings contain a floor space of about 300,000 square feet, the plant being capable of producing 2000 magazine rifles, with their accessories—bayonet, scabbard, &c.—also 1000 spare barrels and bayonets, in addition to cavalry swords, cutlasses, boarding pikes, lances, &c., in a working week of forty-eight hours. The factory is worked by means of a total engine power of 1050-horse power.

The number of different operations in the manufacture of components, Lee-Metford Rifle II proper, is about 1500, and with accessories, such as sight protector, handguard, bayonet and scabbard, oil bottle, and pull-through, the number is increased to about 1750.

Among those present on Tuesday were Mr. George A. Goodwin—president—Mr. J. C. Fell and Mr. G. M. Lawford—members of council—Messrs. W. H. Ball, W. Benbow, D. B. Butler, W. G. Cooke, W. H. Dallimore, J. H. Davies, W. H. Hardy, F. Hovenden, F. A. Robinson, S. Simmelkjor, W. T. Sugg, and G. A. Pryce Cuxson, secretary.

A SPARE length of nickel steel shafting constructed for the American liner Paris has tensile strength of about 90,000 lb., probably 25,000 lb. more than any British or German steel shaft, so the *Engineering and Mining Journal* says.

# CHANDLER'S COMPOUND THREE-CRANK YACHT ENGINE

MESSRS. BUMSTED AND CHANDLER, HEDNESFORD, ENGINEERS

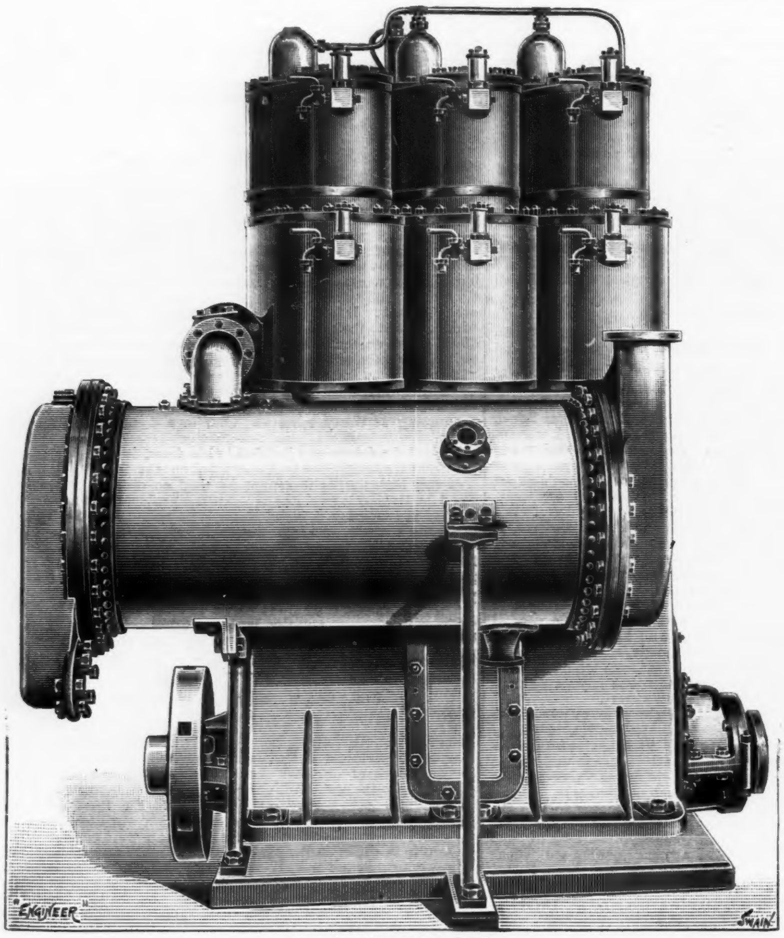


Fig. 1-CONDENSER SIDE

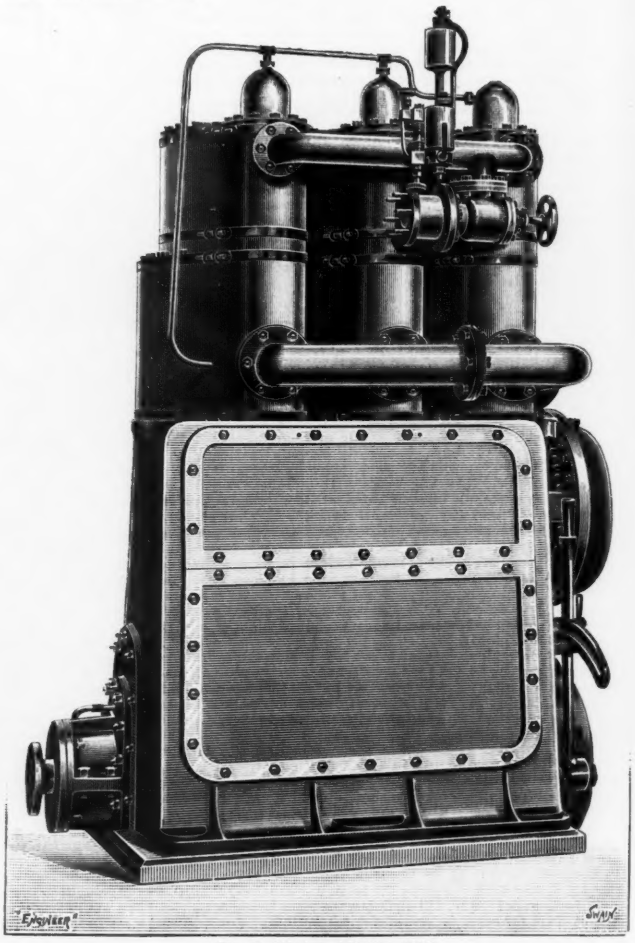

Fig. 2—VALVE CHEST SIDE

## BUMSTED AND CHANDLER'S YACHT ENGINE.

THE above engravings illustrate a set of engines made by Messrs. Bumsted and Chandler, for steam yachts and launches. The engines illustrated have recently been constructed and fitted into the steam yacht Etheldreda—owned by Mr. F. B. Bumstead, the senior partner of the firm. The results have exceeded the expectations of the makers. The engines are of 150 indicated horse-power, and are of the three-crank compound type. The yacht was built and engined two years ago by a first-class firm on the Clyde, but it was found impossible to obtain the silent working desirable on a pleasure yacht, and necessity became the mother of this new departure; the original double-acting compound engines and condensing arrangements were removed, and the new single-acting engine and condensing plant substituted, with the result that a great saving in space in the engine-room is effected. This, coupled with cleanliness, and an entire absence of splashes of oil, steam leaking from piston and valve rod glands, silence, and absence of vibration, renders the alteration a distinct gain from every point of view.

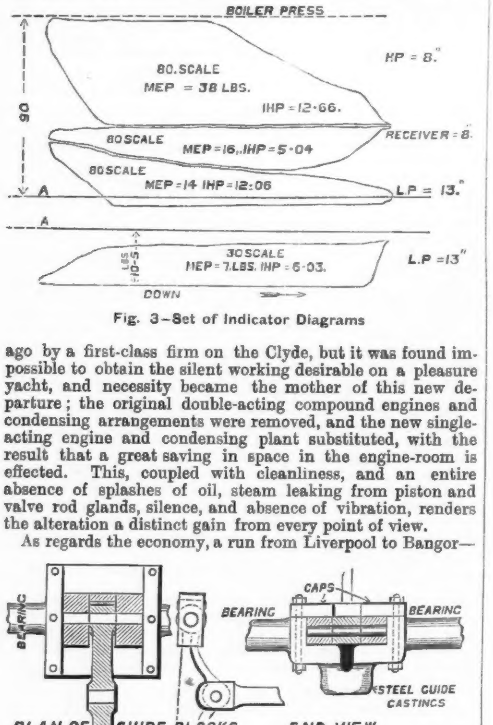

Fig. 3—Set of Indicator Diagrams

As regards the economy, a run from Liverpool to Bangor—when the diagrams were taken—proves the new engines to be more economical in steam than the former engines, and since then a trip from Bangor to Torquay has shown that is is far easier to maintain steam than it was with the old engines running at the same speed. From the first start the new engines have, we are informed, worked entirely successfully and without a hitch of any kind. The thrust block is formed in the after bearing of the engine; a stream of oil constantly flows through it and keeps it cool and clean. There are three high-pressure and three low-pressure cylinders of 8in. and 13in. diameter respectively; the stroke 13in. The cylinders are all close as possible together, but are cast separately. The valves being at the side of the cylinder, are in a suitable position for being worked by a reversing valve gear of the Hackworth type, improved by Mr. Chandler.

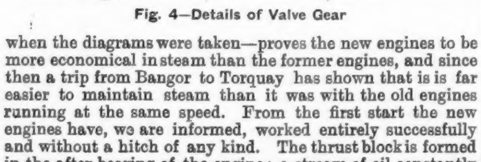

Fig. 4—Details of Valve Gear

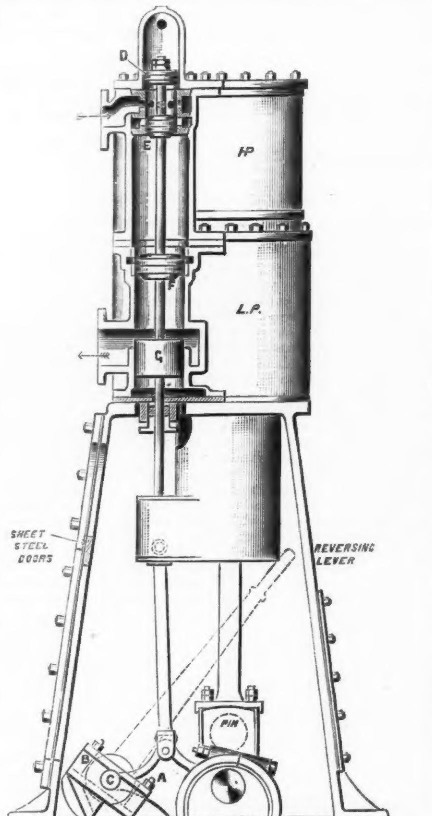

Fig. 5—VALVES AND VALVE GEAR

Great care has been bestowed on this gear, and all the working surfaces are large, see detail views, and immersed in oil, as are all the parts of the engine inside the crank chamber.

A small fly-wheel is shown at the forward end of engine; this is simply for barring round when steam is not up. Fig. 3 shows the four indicator diagrams taken at sea when the engines were running at 202 revolutions per minute with 90 lb. boiler pressure; it will be seen that this pressure is also maintained in the high-pressure cylinders, showing that the valves and ports are of ample size. At this comparatively low pressure, the engines indicated 107-horse power, but they are constructed for 140 lb. pressure, and it is ultimately intended to put in a water-tube boiler for this pressure, when the engines will indicate about 150-horse power. The new engines, condenser, and pumps are only 5 cwt. heavier than the old engines, and the makers state that the next they make of this size and power will be 10 cwt. lighter. The crank shaft is of Siemens-Martin steel, the excentrics being forged solid with the cranks. The arrangement of the valve gear and valves is shown by Fig. 5, and by the detail Fig. 4. The condenser shown in Fig. 1 is sufficient for 150-indicated horse power. It contains 291 brass tubes, 0·75 outside diameter, the cooling surface being 257 square feet.

## THE MUSHKAF BOLAN STATE RAILWAY.

QUETTA is the old capital of Baluchistan, and is now our largest military cantonment on the North-West Frontier of India. The Pishin Plateau, on which this interesting town has been built, rises over 5000ft. above the level of the sea, and many of the high peaks round it are from 4000ft. to 6000ft. higher.

Within the last ten years Quetta has been developed into a first-class *place d'armes*, and many of our foremost soldiers seem to think that the Quetta defences will preserve our Indian Empire against the attack of the Northern invader. The art of modern war, however, demands for success unbroken communication with the base, and it is that necessity which has caused the Mushkaf Bolan Railway to be undertaken after having been shelved for about five years. Quetta is now connected with India by the Sind Pishin Railway, which, though a bold undertaking, has never been a success; and its usefulness as an aid in a campaign is utterly destroyed by the persistent slips at Mud Gorge, which, though instructive to the engineers, are certainly destructive to continuity of carriage between India and the Pishin Plateau.

Such being the case, a project for an absolutely safe line of railway was demanded by the military authorities, and the Mushkaf Bolan Railway, which is now approaching completion, is expected to fulfil that requirement. It might now have been on the eve of opening for traffic but for the scattering of scanty funds over a number of public works, instead of concentrating them on the most important, since the financial position of the Government of India has become so involved, owing to the depressed state of its silver currency. A broad policy in dealing with the funds for public works in India will, however, never be initiated so long as the portfolio of the Public Works Minister continues to be entrusted to either an ex-magistrate, or an ex-soldier, waiting for higher appointments.

The new line leaves the North-Western Railway at the old frontier station of Sibi, and runs due north-west for about 65 miles, where it strikes the southern end of the Pishin Plateau, along which a line of rails has already been laid into Quetta itself.

The Sibi station is 430ft. above sea level, and the summit is 5900ft. above the sea, the total rise being nearly 5500ft. in about 60 miles. The gauge of this line is 5ft. 6in., and the system of "bunching" the steepest gradients has been developed with special consideration for convenience of working with auxiliary engines, an arrangement which will enable the traffic to be carried forward as on a ruling gradient of 1 in 55. Another feature of construction is the refusal to repeat the errors of the Sind Pishin alignment which skirts the spurs of the shale and disintegrated sandstone hills, while on this new railway such spurs have been tunnelled, thus avoiding any disturbance of their slopes. Although there is not so bold a piece of engineering as the "Chuppar Rift," there is, on the other hand, no "Mud Gorge" on this new line, care having been taken to avoid running unnecessarily into engineering difficulties merely for the sake of display in trying to overcome them.

The country traversed by the Mushkaf Bolan Railway may be divided into three well-defined sections having distinctly different features. The first thirty miles are very rough and cut through numerous high rocky spurs, requiring thirteen tunnels and a number of large bridges, the ruling gradient being 1 in 55. The next twenty miles are over an open, stony, waterless country along the base of steep sloping limestone hills, and requiring an abnormal number of bridges to pass the storm waters that occasionally pour down the numerous gorges which deeply score the hill sides, and if checked would simply overwhelm the line with masses of rocks and boulders.

The upper sixteen miles are in a wild country of high, bare limestone hills, through which the Bolan River has cut a deep tortuous channel. Some idea of the difficulty of this section as an engineering achievement may be obtained from the fact that the railway has to cross the Bolan torrent nine times in four miles, which necessitated the most careful individual designing to adapt the bridges to the many varied conditions of construction. On the old Bolan line the bridges were very carelessly placed, so that the flood-water often impinged broadside on to the piers, which were actually battered to pieces by the boulders dashed against them. In the Mushkaf Bolan bridges this danger has been obviated by constructing all piers parallel to the axis of the river, however much skew that may be, and some of the piers have their cut-waters built something like the piers on Canadian railway bridges for parting ice floes. All the masonry is laid in Portland cement mortar.

There are five tunnels on this upper length, and the ruling gradient is 1 in 25. The tunnelling through the treacherous shales, with soft sandstones and disintegrated limestones, has been very arduous, and the most of the 10,000 lineal feet has been done with native miners. The Panir tunnel, 3000ft. long, is the longest tunnel, and is the only one at which compressed air machinery was used; and, in order to work both faces simultaneously, the compressed air has been carried in iron pipes over the summit of the hill, which is 1000ft. above the tunnel. The average progress of the headings worked out to 13 lineal feet per day. The tunnels and the masonry of all the bridges are built for the double track. All tunnels on the straight are 29ft. wide, and some had to be extensively timbered, the general principle for conducting these works being that nothing is so expensive in tunnelling as a cave in. The girders are heavy, and they have been designed to carry the track through on ballast laid on corrugated iron flooring, as was first introduced in India on the Delhi Kalka Railway.

On the "bunched" steep gradients the permanent way is of flat-footed rails, weighing 100 lb. to the yard, laid on steel trough sleepers, this being the heaviest section of rail as yet introduced into India. A temporary track is laid along the upper thirty miles of the line, over which trains work regularly for carriage of materials to the sites of works; and at one place there is a "zigzag" on the ruling grade of 1 in 25, rising 70ft. in a horizontal distance of less than half a mile. At the Panir tunnel there is a temporary rope incline on the three-rail system—that is, with the centre rail common to both tracks—with passing places in the middle, the slope throughout being 2½ to 1, or 40 per cent.

The country through which this new line passes is practically waterless, and is totally uninhabited. Water has had to be brought in wrought iron pipes from springs long distances apart, and is distributed for many miles along the line in smaller pipes for masonry and drinking purposes. The heat in the lower lengths during the summer is terrible, while in the upper lengths the cold is very severe during the winter, when work is often stopped by severe blizzards. The whole of the labour has had to be imported.

To construct a railway on the 5ft. 6in. gauge through such a country, under these conditions, is indeed an engineering achievement; and the Government of India were fortunate to be able to entrust this heavy work to so experienced an engineer as Mr. James Ramsay, M. Inst. C.E., the engineer-in-chief who, under the rigid rules of the Indian Public Works Department, must retire just before his work is completed. Mr. Ramsay brought a ripe experience to the frontier railways in 1885, since when he has been able to profit by the negative lessons taught on the Sind Pishin, the improvement of which railway was entrusted to and carried out by him, after it was handed over to the North-Western Railway to work.

From the reports that have reached us the construction and design of the Mushkaf Bolan Railway are most satisfactory, and can compare with any line in any part of the world; and completely removes all anxiety that, when the stress of war shall unhappily tax England's resources, in the far North-west of India, at any rate, the failure to strike will not be due to the obstruction of the line of railway communication between Sibi and Quetta.

---

The sea-wall at Filey, erected to protect the land from the inroads of the sea, was lately declared complete by Lord Herries, Lord-Lieutenant of the East Riding. Commencing at the North Ravine, the wall runs in two sections to the Crescent Hill, a distance of over 700 yards. A slipway which divides the two portions near the Spa Saloon is spanned by a steel bridge. The foundation of the wall is of concrete, and it is further protected at its base by a concrete apron, backed with a layer of hand-picked stone. The space between this layer and the front of the wall has been filled with concrete, laid in mass, a wide layer of this material being placed with concrete blocks of superior quality to resist the action of the waves. The structure has an average height of 19ft. above the sand, the promenade being 11ft. above high-water mark. A bull-nose ledge placed immediately underneath the coping has the effect of turning the waves from the promenade and throwing them back into the sea, and the coping is surmounted by an iron railing 3ft. 4in. in height. The promenade consists of an asphalted pathway 12ft. wide, leaving behind a large open space, which will be laid out in ornamental plots, and will also afford accommodation for shelters, and, if desired, for a band-stand. The *Building News* says the works have been carried out at a cost of £15,000.

## FYFE'S APPARATUS FOR STEAMING COMPRESSED HAY.

MESSRS. J. & F. HOWARD, BEDFORD, CONSTRUCTORS.

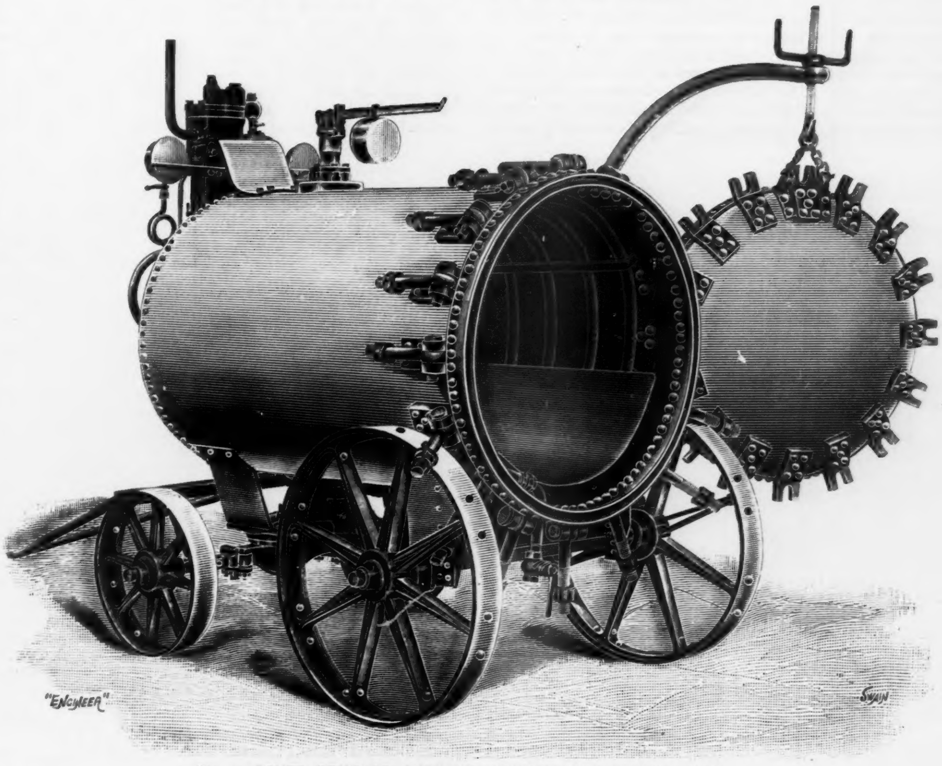

Fig. 1.—COVER REMOVED SHOWING INTERIOR AND STEAM COILS.

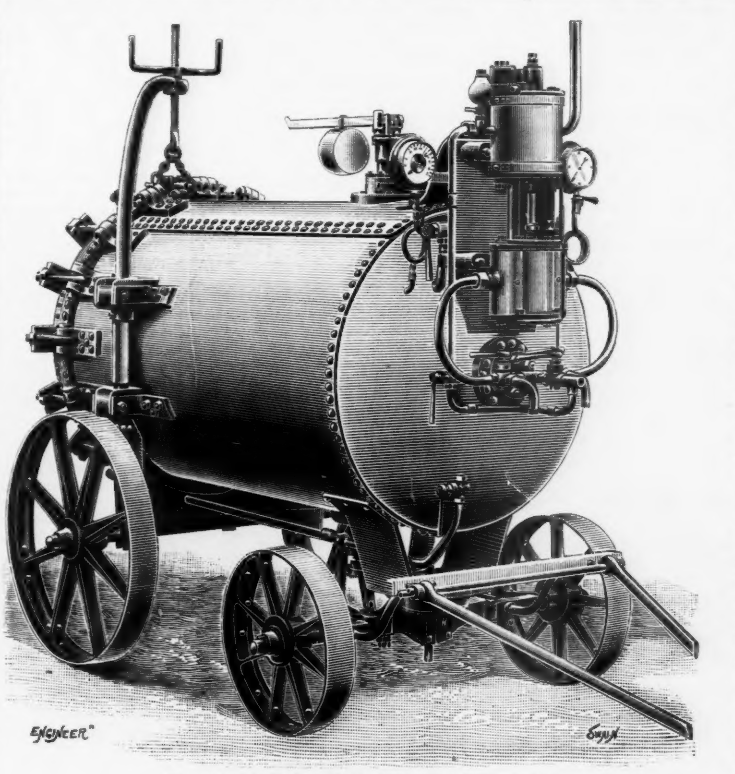

Fig 2.—FRONT END SHOWING AIR COMPRESSOR.

## THE ROYAL AGRICULTURAL SOCIETY'S SHOW.

In our issue of the 29th ult. we described briefly Mr. D. A. Fyfe's new system of hay-making. We are now enabled to place before our readers illustrations of the actual apparatus exhibited—see Figs. 1 and 2. It is generally known that the old-fashioned plan of slowly steaming inferior chaffed hays impregnates them with moisture which is difficult to eliminate; but in Fyfe's system the object is to compress the uncut hay as tightly as possible into bales, with the object of retaining heat for drying it more effectually, and then submitting it to a steam pressure of 60 lb. to 80 lb. Loose or exhaust steam would be useless, as it could not possibly permeate a hard pressed bale; any such attempt would be merely cooking the outside whilst leaving the inside. The apparatus shown consists of a strong steel cylinder, 6ft. long by 4ft. diameter, mounted on four wheels, and with a removable cover at one end for the introduction of the material to be cooked. The other end of the cylinder is cambered, and carries a Westinghouse combined vacuum pump and air compressor, supplied with high-pressure steam. The cover, which is slung from the arm shown when not in use, is provided with substantial steel lugs which engage with hinged bolts secured to the cylinder, and the rim is faced up to form an air-tight joint with the cylinder when the material is placed inside. Inside the cylinder is provided a heating coil and a floor plate. By means of suitable valves and pipes the pump may be employed to create a vacuum in the cylinder, after which steam is admitted, then blown off, and the vacuum pump is again brought into action to exhaust the remaining steam. The process is as follows:—The hay being closely pressed into bales to a density of 20 lb. per cubic foot, is now packed inside the cylinder, and the door being closed, the pump connected with the cylinder is set going to produce a vacuum. Steam under high pressure is then admitted and allowed to permeate the hay for fifteen to thirty minutes' duration, when it is blown off, and what remains is exhausted by means of the vacuum pump. For ordinary requirements the cylinders are made 20ft. long by 6ft. diameter, and are capable of holding from 2½ to 3 tons of compressed baled hay at each operation. In dealing with wet hay under Fyfe's system, hot air under pressure and at a temperature of 300 deg. may be used instead of high-pressure steam. One hour is said to be the time required to put hay through the entire process; fifteen minutes are required to fill the cylinder with hay and affix the door, whilst another fifteen minutes suffice to produce a vacuum and to get steam up to 80 lb. pressure. The cooking requires twenty minutes longer, a further ten minutes are needed to exhaust the steam, the bales are then ready to be turned out in a finished state. Besides possessing the advantage of great economy as regards fuel consumption and labour, this process, it is said, renders feasible the use of new hay for feeding cattle. Moreover the hay being supplied in the form of bales, a railway truck is capable of holding more than twice as much as in the old truss form, thereby reducing proportionately the cost of transit. With the chemical features of this new process we shall not pretend to deal; but we may state that the result of analyses made by Mr. J. Barker Smith, L.R.C.P., Lond., upon different qualities of hay—treated and untreated—serve to show that the indigestible wood fibre is diminished, while the digestible fibre and carbohydrates are increased.

In our general notice of the miscellaneous exhibits reference was made to the new wheat conditioner exhibited by Messrs. E. R. and F. Turner, Ipswich. We now illustrate the machine, which consists of an upright double cylinder, both barrels covered with perforated metal, and revolving slowly upon one central spindle. The wheat falls in a thin stream between the two perforated cylinders, and the upper part of the machine, for two-thirds of its length, is devoted to heating the wheat and evaporating from it any moisture left after treatment on the washing and whizzing process, or in a damping warm. The drying is accomplished by means of a hot-air current, which passes into the cylinder at the top and out through the perforated covers and the wheat between them. The bottom part, about one-third, of the conditioner is supplied with cold air in a similar manner for cooling the wheat before sacking off or storing in bins.

TURNER'S NEW WHEAT CONDITIONER—*See page* 31.

A scraper on the bottom table takes off the wheat as it descends from between the covers. The depth of wheat taken off at each journey of this scraper is regulated by its connection with a loose flap on the top of the machine, which travels on the grain in the top hopper, and rising or falling, according as the feed is increased or decreased, causes a corresponding rise or fall of the scraper at the bottom.

## THE DANUBE REGULATION WORKS.

By Bela Gonda.

(*Continued from page* 496, *Vol. lxxvi.*)

THE national economical importance of the Danube for inland navigation was acknowledged, before the beginning of these works, by the Count Stephen Széchényí, who for his activity in the regeneration of Hungary was honoured by his compatriots with the name of the "Greatest Hungarian." He several times visited the Lower Danube, and strived to persuade the Court of the importance of making the cataracts navigable. Meanwhile, the surveys already mentioned were begun on the Lower Danube, under the direction of Paul Vásárhelyi, engineer; and by the indefatigable ardour of Széchényi, the Steam Navigation Company was founded simultaneously with Count Széchényi going, on June 5th, 1833, by the steamer Ferencz to the Lower Danube.

On studying the state of the Lower Danube, Széchényi was convinced that the technical resources of that time were insufficient to render the cataracts navigable; and even with great effort and pecuniary sacrifices the work could not have been carried out completely in the time. But to ensure the maintenance of the traffic on the Lower Danube, he decided to construct a road of communication from the Moldova beyond the Iron Gate, and he proceeded to elaborate the plans under the direction of Vásárhelyi. After the Government had approved of the necessary expenses, Széchényi began, in 1834, the construction of this road, which was opened for communication in 1837. This road had for its object its use as a means of transport when low water impeded the navigation. It is called, after its promoter, Széchényi Road, and is a worthy companion to the Trajan road on the opposite shore, which is also an admirable and magnificent piece of construction. During this time Vásárhelyi finished his plans at Plavisevicza in 1834 for rendering the cataracts of the Lower Danube navigable, on the basis of the precisely and conscientiously executed surveys which, taken on October 23rd, 1834, at unusually low water, gave a true exposure of the state of the cataracts.

Vásárhelyi hastened to make use of the water's unusual lowness by having the rocks removed in the navigable way — as far as this was possible by manual labour—in order to facilitate the navigation in the cataracts. But the plans designed by Vásárhelyi were not adopted on account of the difficulties which were raised in the meanwhile. Later on, the occasion of the Crimean War, when the Austrian armies occupied Roumania, the attention of their leaders was called to the regulation of the cataracts of the Lower Danube.

In view of this object the Austrian Government sent thither in 1854 the engineer, Meusburger, and later the chief engineer, Gustave Wex, in order to study the Iron Gate and to design plans for its regulation. They made several alternative plans, and executed also several surveys, especially at the cataract of the Iron Gate, but the execution of the works was again postponed.

After the Crimean War, the other great European Powers concerned themselves in this question of navigation on the Danube. The treaty dated at Paris the 30th March, 1856, stipulated the right of navigation of the Danube, but without touching the question of removing the hindrances to navigation. In 1871 the Danube Steam Navigation Company took the matter up, and engaged the American engineer, MacAlpin, for the study of the cataracts, who, by reason of the manner in which he carried out the regulation of the Missisippi, had acquired a reputation for this class of work. MacAlpin made a careful study of the Lower Danube, and gave his opinion as to the regulation of all the cataracts, and prepared plans, which again were not executed.

The London International Congress in 1871 gave a new impulse to the regulation of the Lower Danube. The Congress, in maintaining the right of navigation, authorised the littoral States to execute the necessary works for the removal of the navigation hindrances, and to levy customs in order to defray the expenses till the capital and interest were paid back. In consequence of this treaty, the Governments of the littoral States delegated an International Commission, consisting of engineers whose business it was to study the cataracts of the Lower Danube, and to devise plans for rendering them navigable. The Hungarian Government delegated Louis Bodoky, engineer; the Austrian Government, Wawra, engineer; the Government of Turkey, the Bey of Mugel, with a suitable engineering staff. The International Commission having executed the necessary surveys for the plans, determined at first as to the principles of the general regulation, that through the cataracts, everywhere in the channel, possibly out of the navigable way, canals with a bottom-width of 60 metres, and with a depth of 2 metres under the lowest water-mark, should be constructed, and for regulating the direction of fall and the velocity—where it prove necessary—dykes should be built reaching over the inundation surface; and finally in considering the greater velocities also, after the regulation, the question of towage should be studied.

The Commission further, considering the greater pretensions of modern navigation, decided that the sluice-canals should be abandoned, and proposed that open canals should be constructed. On the basis of this principle, and after the plans and surveys of Vásárhelyi, the Commission elaborated new plans, embracing the whole Lower Danube. But the works projected in 1873 and 1874 by the International Commission to render the Lower Danube cataracts navigable, were again postponed, till after the Turco-Russian war, the Congress at Berlin in 1878 deliberated on this important question, which had been so long under consideration. The Austro-Hungarian monarchy concluded on the 8th July, 1878, a treaty with Servia, as one of the littoral States of the Lower Danube, proposing the execution of these works without the pecuniary help of Servia; but in order to facilitate the works in question, Servia was bound to permit the free use of her shores, and being assured from the Austro-Hungarian Monarchy that, in view of the navigation of the Lower Danube, she would be treated as one of the most favoured States, it was determined in the Art. 57 of the Berlin Treaty dated 13th July, 1878, that Austria-Hungary should be charged with the execution of works at the cataracts of the Lower Danube, and that the littoral States of this part of the river should do everything to facilitate this work. The same Article further stated, that conforming to the Art. VI. of the London Treaty, concluded on the 13th March, 1871, Austria-Hungary was authorised to cover the expenses of these improvements out of the custom dues which would be levied.

This very important resolution of the International Congress at Berlin, charging the most interested great Power with the execution of these works on the Lower Danube, approached the realisation of this long debated question. The situation became still more favourable for the great work, when the Governments of Austria and Hungary agreed that the execution of the work should be carried out by Hungary, and consequently the right to levy tolls, in conformity to the Berlin treaty, was conferred upon the Hungarian Government.

From this time the Hungarian professional circles began to interest themselves in the important question of the execution of these works, and in view of their execution in conformity to the requirements of navigation, and to the exact conditions of the river, the Hungarian Government asked the eminent foreign engineers, who were invited in 1879 to give their opinion on the works which were to be executed in consequence of the extraordinary inundations in the valley of the Tisza, to examine also on the spot the plans drawn by the International Commission for rendering the cataracts navigable on the Lower Danube and at the Iron Gate, and to give their opinion about the project. In consequence of this, the foreign engineers made a careful study of this all-important question, and in their report they touched on all the particulars of the projected works, proposing several modifications. Later, the "Donau Verein" (Danube Society) of Vienna developed great activity in this direction, and the Austrian Engineering Society also studied the question. Besides this, the "Donau Verein" published plans and descriptions referring to the regulation, beginning with the plans of Paul Vásárhelyi and other existing ones up to the end of 1879, and deliberated on this work in the Austrian Engineering Society. This contributed also to excite general interest in the movement.

But unfavourable circumstances postponed the execution of the Lower Danube works again; and not until 1883 was the question taken up by the Minister of Public Works, Baron Gabriel Kemény, and especially by the Assistant-Secretary of Public Works, Gabriel Baross, who died in his prime on March 8th, 1892, as Minister of Commerce, and who acknowledged the great importance of the navigability of the cataracts on the Lower Danube, in view of inland navigation, as well as foreign traffic. There was considerable difference of opinion regarding the plans of the International Commission and the proposals of the foreign engineers, and neither the International Commission nor the foreign engineers had time or occasion to execute extensive and particular surveys regarding the channel and the water of the cataracts, as required by the final settlement of the regulation. Accordingly, the Ministry of Commerce engaged Ernest Wallandt in 1883, general inspector of public works, to make a study about the channel and waterway of the cataracts, and to submit a project for the final determination of these works, to examine the projects proposed by the foreign engineers, to prepare plans and estimates, and finally to make experiments for the purpose of ascertaining the expense of blasting the rocks under the water.

Wallandt, having accomplished his mission, presented in the same year—in conformity with the instructions—the plans and surveys executed by him. On the basis of these plans the works were fixed in the following manner:—

Their principal and final object was to ensure the unhindered navigation through the cataracts of the Lower Danube. In order to attain this object two problems were to be solved; the one was to do away with the small depth during the low waters, the other to moderate the excessive velocities. In order to accomplish this, it was suggested to deepen the navigation-channel through the cataracts, with a bottom width of 60 metres, with a depth of 2 metres below the lowest water mark ever observed, namely, on the 23rd October, 1834. According to the opinion of competent authorities, the bottom width of 60 metres will be quite sufficient, even for the greater demands of the navigation which is certain to develope on the Lower Danube, especially as it is noticed that the navigation channel to be executed in the river is projected in straight lines, or, where this is impossible, slight curves will be adopted, so that the entrance of the ships—considering the natural current of the river—should take place without difficulty. The depth of 2 metres in the navigation channel will suffice for the wants of the Hungarian navigation on the Danube, especially seeing that the lower water level adopted as datum low has never been reached since 1834, and that the normal water mark is higher at least with 0 5 metre and more, so that the minimum depth of the navigation channel may be taken at least at 2 5 metres. The canal projected through the Iron Gate, however, will be an exception, as during the construction the originally projected depth of 2 metres was changed to 3 metres.

The principal object of the regulation of the cataracts being, firstly, to construct a waterway meeting the wants of river navigation, and secondly, to moderate the excessive velocities of the cataracts, it was decided to restrict the channel within stone dykes. In consequence of this, the rapid fall of the water will be distributed over greater surface, and the high velocity which impeded the navigation hitherto will be as much as possible moderated. But we must remark, that the moderation of the velocity has naturally its limits imposed by the local circumstances, which cannot be evaded, and, in consequence, it has been found necessary to arrange for a system of towage, especially at the Iron Gate Canal, and for this plans have already been submitted.

On page 34 we publish engravings showing some of the rock smashers and dredgers used on the works.

(*To be continued.*)

Building and Engineering Trades Wages at New Orleans.—According to a recent report of the British Consul at New Orleans, the present rates of wages in the building and engineering trades there are—for bricklayers, 16s. per day; cabinetmakers, 12s. to 16s.; carpenters, house, 10s.; carpenters, ship, 12s.; gasfitters, 10s.; painters, 11s.; paperhangers, 12s.; pipelayers, 10s.; plumbers, 12s.; stonemasons, 10s.; boilermakers, 14s.; coppersmiths, 13s. to 15s.; ironmoulders, 12s.; machinists, 10s. to 14s.; apprentices, 2s.; labourers, 6s.

## RAILWAY MATTERS.

The new Bareilly-Rampore-Moradabad Railway has been opened for regular traffic.

The Brussels Common Council has adopted a plan for an underground cable railroad which is to extend from the upper to the lower town.

A Reuter correspondent, telegraphing from Blantyre, Africa, says the construction of the telegraph is now making rapid strides, and the line will reach Zomba by the end of June.

The secretary of the Imperial Institute of Engineers of Russia notifies that the tramway lines of St. Petersburg are to be equipped with the best street railway motors that can be obtained.

It has now been decided to proceed with the construction of the new railway to Crowland, and thus connect that town with the Great Northern Railway Company's system in South Lincolnshire.

The Anatolian Railway suffered considerably in the recent earthquake at Constantinople, four or five stations being wrecked and others more or less damaged. The traffic, however, was not suspended, and the line itself is in good order.

We understand that the Metropolitan Railway Company have intimated a desire to do something to remedy the present state of the atmosphere in the underground railway tunnels, and have offered to consider schemes for ventilation.

The Pacific section of the Siberian Railroad, which is to extend from Vladivostock north-easterly to the Amoor River, following the Ussuri River a considerable distance, is called the Ussuri Railroad, and a few miles were built in 1892. Last January it was opened 122 miles, to a station called Chernigovkce.

We understand that the Egyptian railway administration have given a contract for twenty-four six-wheeled locomotives and tenders all complete to the Société Franco-Belge at the price of £40,553, delivery to be made within forty weeks. The next lowest tender was that of an English firm at £41,280, delivery within thirty-two weeks.

Another step has been taken toward establishing through railway communication between Calcutta and the Burmese frontier. A special survey of the Madaripur extension of the Bengal Central Railway and of the country and watercourses as far as the nearest point of the Assam-Bengal Railway, is about to be undertaken under the orders of the Government of India.

The Tottenham and Forest-gate Railway has been opened for passenger traffic. The length of the new line is six miles four chains, and there are six stations on the route. The line has been constructed in a most substantial manner, and the stations are convenient and well designed. The chief engineer was Mr. A. C. Pain, and the contractors were Messrs. Lucas and Aird.

At the beginning of the year 1860, Russia only possessed 1250 verstes of railway—verste=·663 of a mile—and in 1865 this total had only reached 3360 verstes. But between 1865 and 1875 an enormous advance was made, and 13,652 verstes were opened for traffic. In 1875 the total length of the system was 17,012 verstes. During the following years 6010 verstes were added. Since 1885 the construction of Russian railways has received a new impulse, and the system now shows a total development of 31,804 verstes constructed, and 3113 in course of construction. This length is not inclusive of the line at present being built in Siberia.

In a paper in the *Schweizerische Bauzeitung*, discussing street railroads with special reference to the new electric road at Zurich, in Switzerland, Mr. P. Schenker points out, among other things, that while in the United States about 60 per cent. of all the street railroads are worked electrically, representing about 7500 miles of road with about 17,000 cars in use, there are at the present time in operation in Europe only about 260 miles of electric street railroad, with an equipment of 720 cars. The *Railroad Gazette* draws attention to the fact that these are divided up among about fifty different companies. A number of roads, however, are now under construction, and will help somewhat to swell this meagre total.

The difficulties which railways sometimes experience, owing to the lights of the tail and side lamps of trains going out from various causes, have been successfully overcome by an officer of the Midland Railway Company, who has constructed a lamp which, by an ingenious arrangement, practically removes all risk of the light being extinguished during the journey. Another advantage claimed for the new lamp is its great simplicity and adaptability to burn petroleum or any other kind of cheap mineral oil, which has not previously been generally used in train signal lamps because no satisfactory lamp has been invented, although such oil has for years been used in fixed signal lamps. The lamp effects, it is claimed a saving in consumption of upwards of 80 per cent. at present prices if the common Scotch paraffin is used as compared with the rape or colza oil burning lamp; and the Midland Railway Company have adopted it upon their system for both passenger and goods trains with most satisfactory results. The use of the lamp is not restricted to tail and side lamps only, as it is also adapted for locomotive engines, tramcars, &c.

The Railway Ammonia Motor Company has recently had built at the works of De La Vergne Refrigerating Machine Company in New York a motor car upon its system, and a trial of this car has been made at the De La Vegne works. Anhydrous ammonia in this car is charged in a reservoir, which is surrounded by a tank filled with hot water. From the reservoir it passes into the cylinder, where it acts on the piston expansively, precisely as steam does. The exhaust from the cylinder is conveyed into the water-tank and compressor, where the ammonia is condensed, liquefied in the usual way, and re-used. In the trial made the reservoir was charged until the pressure was about 150 lb., and the car was run about a mile backward and forward before the pressure ran down to 100 lb. *The Engineering and Mining Journal* says it is to be regretted that the ammonia motor had hardly a fair trial. The cylinders are apparently too small to work the motor and a trailer or tow-car, while the mechanical arrangement of the engine is not good, and the power is transmitted to the axle through an intermediate shaft and gearing, the latter always objectionable in a street car. With a better design of engine, and with cheap ammonia, the motor may be able in some places to compete successfully with the electric road.

According to the acting British Consul-General at Constantinople, the Medua-Ferezovitch railway scheme is still in suspense. The proposals of Mr. W. Leatham Bright have been examined by the Technical Commission of the Ministry of Public Works, and approved except as to the amount of the mileage guarantee. The amount asked for was £643 6s. 8d. per mile, whereas the Technical Commission calculated that the revenues of the proposed line during at least the first ten years of its existence could not exceed £450 6s. 8d. per mile, and the Government would be called upon to provide a large annual sum to cover the deficiency. Considering the large amount of provincial revenue that the Ottoman Government has already pledged for railway guarantees, the desire to get at least one line constructed at the contractor's risk is but natural. The risk on a contractor's part is great; the construction of the line from Medua to Ferezovitch would cost at least £1,250,000, while a revenue of £450 6s. 8d. per mile, if realised, would be under 6 per cent. of that sum, without allowing anything for working expenses. A French syndicate is said to be seeking to obtain the concession for this line, demanding in lieu of the customary mileage guarantee a cession of the principal forests in the districts traversed.

## NOTES AND MEMORANDA.

Under the provisions of the Factory and Workshops Act, the Home Secretary has certified that the processes carried on in the tinning and enamelling of metal hollow ware and cooking utensils are dangerous or injurious to health.

M. Dufour, Professor of Astronomy at the University of Lausanne, has discovered an easy method of ascertaining the exact distance of any object on the horizon. First find the height from which the observation is taken, express it in decimetres, multiply it by one-fourth, and take the square root of the result. Thus, supposing the eye to be 8 metres, or 80 decimetres, above the level of the sea, the quarter of this—20—is added to the 80, and 100 is thus obtained, of which the square root is 10. This, says *Fairplay*, is the solution, expressed in kilometres.

The report of the Astronomer-Royal, Mr. W. H. M. Christie, for the year May, 1893—May, 1894, states that the variations of magnetic declination, horizontal force, and vertical force, and of earth currents have been registered photographically, and accompanying eye observations of absolute declination, horizontal force and dip have been made as in former years. The period has been one of much less magnetic activity than last year, but there was a large increase occurring in February, 1894, at the time of the great sun spot. Copies of the magnetic and earth current registers during the disturbances of February 20th—March 1st and March 30th—April 1st, have been supplied to Mr. Preece for discussion in connection with disturbances on the telegraph lines.

The following is an analysis of Bermuda asphalt:—Specific gravity at 60 deg. Fah., 1·071; bitumen soluble in carbon disulphide, 97·22 per cent.; mineral matter or ash, 1·5 per cent.; non-bituminous organic matter, 1·28 per cent.; portion of total bitumen soluble in alcohol, 11·66 per cent.; portion of total bitumen soluble in ether, 81·63 per cent.; loss at 212 deg. Fah., 1·37 per cent.; loss at 400 deg. in ten hours, 17·8 per cent.; loss at 400 deg. calculated to amount of bitumen present, 18 308 per cent.; softening point, 113 deg.; flowing point, 150 deg. Physical tests give the following results with two separate sets of samples: Average tensile strength, 399 lb. and 508 lb. at 32 deg., 116 lb. and 204 lb. at 64 deg., and 20 lb. and 44 lb. at 108 deg. The ultimate compressive strength per square inch at 32 deg. was 1750 lb., and at 65 deg. 667 lb.

An apparatus for detecting flaws in iron and steel by electricity is the invention of Captain De Place, of Paris. It consists, says the *American Manufacturer*, of a small pneumatic tapper worked by the hand, and with which the piece of steel or iron to be tested is tapped all over. Connected with the tapper is a telephone with a microphone interposed in the circuit. Two operators are required, one to apply the tapper, and the other to listen through the telephone to the sounds produced. These operators, who are in electrical communication, are in separate apartments, so that the direct sounds of the taps may not disturb the listener, whose province it is to detect flaws. In applying the system one operator places the telephone to his ear, and so long as the sounds produced by the taps are normal he does nothing. Directly a false sound—which is very distinct from the normal sound—is heard, he instantly signals for the spot to be marked. By this means he is able not only to detect a flaw, but to localise it.

A new method for determining the pitches of high tuning forks is described by Herr F. Melde in the current number of *Wiedemann's Annalen*. It is, like the vibroscopic method previously described, independent of the ear, and is based upon the resonance of a rod clamped at one end and vibrating transversely. The laws of vibration of such clamped rods have already been so carefully studied that calculations of pitch, based upon their dimensions and the properties of the material of which they are made, are very reliable. The tuning fork tested was mounted in a wooden block, and placed with one prong lightly touching the end of the rod, so that a vibration of the tuning fork when bowed produced a transverse vibration of the rod. Fine sand was dusted on to the rod. If on bowing the tuning fork the sand did not arrange itself in straight lines at right angles to the length of the rod, the clamp was shifted until it did. The mode of vibration, and consequently the pitch, was then calculated from the number of such nodal lines produced.

At a recent meeting of the Royal Society, Professor T. W. Spencer, in a paper on "Niagara Falls as a Chronometer of Geological Time," after describing the topography and geography of the district, and discussing the laws of erosion, gave—*Nature* says—the following sketches of the history of the Niagara Gorge and Falls:—First episode: Water falling 200ft. in volume, three-elevenths of modern discharge; gorge, 11,000ft. long; duration, 17,200 years. Second episode: River descending 420ft., in three cascades; first stage, only the discharge of the Erie waters; length of chasm, 3000ft.; duration, 6000 years; second stage, drainage of all the upper lake; length of chasm, 7000ft.: duration, 4000 years. Third episode: Same volume and descent as in last, but the three falls united into one fall; length of chasm, 4000ft.; duration, 800 years. Fourth episode: Volume of water as at present, the level of lower lake as to-day; first stage, a local rapid making the descent of 365ft.; work particularly hard; length of gorge, 5500ft.; duration, about 1500 years; the second stage as at present; work easy; length of cañon, 6000ft.; descent of water, 320ft.; rate of recession here taken as the full measured amount of 4175ft. a year; duration, 1500 years. Thus the age of the Falls is computed to be 31,000 years, with another thousand years as the age of the river before the nativity of the Falls. The turning of the Huron waters into the Niagara was about 8000 years ago. A difficult question was the amount of work done in each episode. This was in part determined by the position of the remaining terraces corresponding to different stages of the river, and by the changing effects of erosion.

Investigations on the influence of moisture on chemical action are reported in a recent number of the "Proceedings" of the Chemical Society. The various actions spoken of in a preceding report have now been brought to definite conclusions, and are as follows:—Sulphur trioxide does not combine with highly purified lime, but a trace of moisture brings about vivid incandescence, Dry copper oxide is also without action on sulphur trioxide. Purified and dried lime does not decompose dried ammonium chloride, which may be sublimed from the mixture without evolving any ammonia. Purified and dried nitric oxide gives no brown fumes with dried oxygen, but a trace of moist air causes them to appear at once. A mixture of purified and dried hydrogen and chlorine can be exposed to daylight for four days without more than three-fourths of the gases combining. Ammonium chloride, heated in a vacuum in a soft glass tube, leave a residue of ammonia gas; but when dried and heated in a hard glass tube, no gaseous residue is obtained. This led to the investigation of the vapour density of dry ammonium chloride, which was shown to be normal, 28·7 being the mean result of six experiments. With regard to the theory of the subject, the author believes that an electro-chemical hypothesis is applicable. Separation of dried ammonia and hydrogen chloride gases takes place when plates with opposite electrical charges are introduced into the mixture, though the action cannot be electrolytic, since discharge is, under the circumstances, impossible. Similar separation was noticed with air and with a mixture of dried hydrogen and oxygen. Electric discharge, when not of high tension, will not pass in dried gases; but the high-tension discharge does pass, and renders it possible for the low-tension discharge to pass afterwards. With regard to the influence of moisture, it appears that what holds for chemical combination holds also for electrical discharge, and that there is great significance in the apparent similarity in the two cases

## MISCELLANEA.

The Admiralty have ordered all the ships of the Royal Sovereign class to be fitted with bilge keels.

According to intelligence from Vienna, a preliminary concession has been granted to a Russian contractor for making a ship canal between Trieste and Vienna.

We read that experiments with oil for fuel on tug boats are being made at Chicago, under the auspices of the health department, the object being to abate the smoke nuisance on the river.

The old agricultural implement and engineering works of Messrs. Wedlake and Co., Hornchurch, which originated over 100 years ago, are being extended by construction of new works, foundry, and plant.

The Russian Government are about to add to their Navy two powerful ironclads. One, to be named the Grand Admiral Apraxine, 4120 tons, is intended for the defence of the coasts of the Baltic Sea; and the other, called the Rostislaw, 8800 tons, will be attached to the Black Sea Fleet.

The cruiser Crescent has arrived at Plymouth, having completed her voyage to and from Australia. She covered a distance of 25,267 nautical miles on a coal consumption of 6290 tons, and was 82½ days at sea. The longest 24 hours' run was 369 miles on the 5th inst. Her average speed was nearly 15 knots.

The work on the buildings for the mining exposition in Chile, to be held in September, is well advanced, and the probability is that all the arrangements will be completed in good time for the opening. Many exhibits are promised, and there is every reason to expect that the exhibition will be a successful one.

The contract for the construction of the new Trinity Bridge over the Neva, in place of the movable wooden one, has been secured by the French Company at Batignolles. The bridge is to cost five million eight hundred thousand roubles. No English firms appear to have tendered for this valuable piece of work.

The Institution of Naval Architects have issued an official programme for the coming meeting at Southampton, containing a useful map of the district, post-office and railway information, &c. Meetings will be held in the rooms of the Hartley Institute, on the 24th, 25th, and 26th, and for the following two days various excursions and visits have been arranged.

The Tendring Hundred (Essex) Water Company have consented to place at the disposal of the Eastern Counties Coal Boring Association the well which that company bored at Bradfield to the depth of 800ft., and which they then abandoned because no proper water supply was reached. It was at a deep well-boring at Harwich, not far distant, where the first indications of underlying coal were found.

The Corporation of Monmouth called in Messrs. Bramwell and Harris to report on the seventeen competitive schemes submitted for the sewerage and sewage disposal of Monmouth. These gentlemen have now awarded the premiums as follows. The first premium of thirty guineas to Mr. W. H. Radford, C.E., of Nottingham, and the second premium of twenty guineas to Messrs. John Parker and Son, of Westminster.

The question of canal improvement has assumed prominence in the New York constitutional convention. We see among a number of amendments one authorising the transference of the control of the canals to the Government of the United States under certain conditions, one being the enlargement of the canals so as to connect the great lakes with the Atlantic Ocean; another being the construction and maintenance of a ship canal around Niagara Falls.

The Sandycroft Foundry Company, having carefully watched the various developments of electricity in its application to mining work, has now added a department for the manufacture of electrical machinery. This department is under the charge of Professor N. S. Keith, M. Inst. E.E. The Sandycroft Foundry is adapting the Keith system to its own requirements. Preparations are already far advanced for utilising electricity to run every department of the establishment, including the use of electric locomotives, electric cranes, and other appliances.

A new craft is expected to take part in the yacht races at Galveston. She was built in Fort Worth, and may be classed as a whaleback yacht. She is a queer-shaped object, being about 32ft. in length, by about 6ft. beam. She has no straight lines, and is of the shape of a large cigar, pointed at the forward end, and has a whaleback extending from the forward part to about 15ft. aft, and she is claimed to be in all respects absolutely insubmergible. She has air-chambers fitted inside, and her forward bulkheads are air-tight; she also has a centre-board which is very heavy, being of iron heavily weighted with lead, and her rudder is as massively constructed. She draws only 2ft. amidships, and will have but little resisting power, compared with other yachts, when being propelled through the water. She is lugger-rigged.

The official full-power forced draught trial of her Majesty's ship Ferret, built by Messrs. Laird Brothers, of Birkenhead, has been conducted with satisfactory results. The mean speed on the measured mile was 27·62, the maximum speed attained being 28·4 knots. The speed for the three hours was 27·51 knots with 175 lb. steam and 361 revolutions. The Ferret is the first of the new class of 27 knot torpedo-boat Destroyers, her displacement being 258 tons. No. 97 Torpedo Boat, built by Laird Brothers, Birkenhead, on her three hours' full-power trial, made six runs on the measured mile as follows:—Steam, 170 lb.; revolutions, 363; speed, 23·71 knots; and I.H.P., 1690. The speed for the three hours, 23·35 knots, was well maintained. The contract speed is 23 knots. This vessel is 140ft. long, with a displacement of 115 tons.

The deposits of petroleum discovered a few years ago in the Province of Lanhkat, in the northern portion of the island of Sumatra, and along the coast of the Malacca Straits, are being rapidly developed. Concessions have been granted by the Dutch Indian Government to both Dutch and English capitalists, but at present only the Dutchmen have worked their concessions. The area of the lands conceded amounts to 828 square kilometres—318 square miles—and it is believed that this portion of the island is very rich in petroleum. The *Journal* of the Society of Arts says the wells are put down very near to the coast, so that the expense of carriage and shipment are not heavy, and, as the quality of the oil is very good, it is thought Sumatra may, before very long, enter into serious competition with Russia and America, the more so as this portion of the coast possesses a deep and well-sheltered harbour.

Gas motors for pumping purposes are quite extensively employed in Germany, according to the *Journal für Gasbeleuchtung*, which gives a list of forty-two installations, some handling over 4000 gallons a minute. Four of these drive centrifugal sewage pumps at Dusseldorf which together are capable of lifting 16,000 gallons a minute against a head of 16·4ft. The greatest head against which any of the plants is working is at Rottweil. Here a motor of 20 effective horse-power is employed to drive a double horizontal piston pump delivering 132 gallons a minute against a head of 315ft. The two cylinders of the pump are 6·7in. and 6·4in. in diameter, the stroke is 20in., and the revolutions are fourteen a minute. A petroleum motor at Obercassel, installed last year for the waterworks, is employed to raise 110 gallons of water a minute to a height of 230ft. All of the motors are of the Otto pattern from the Gasmotoren-Fabrik Deutz in Cologne. There are numerous instances of this in England.

## TO CORRESPONDENTS.

**Registered Telegraphic Address, "ENGINEER NEWSPAPER, LONDON."**

*** *In order to avoid trouble and confusion, we find it necessary to inform correspondents that letters of inquiry addressed to the public, and intended for insertion in this column, must in all cases be accompanied by a large envelope legibly directed by the writer to himself, and bearing a penny postage stamp, in order that answers received by us may be forwarded to their destination. No notice can be taken of communications which do not comply with these instructions.*

*** *We cannot undertake to return drawings or manuscripts; we must therefore request correspondents to keep copies.*

*** *All letters intended for insertion in* The Engineer, *or containing questions, should be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever can be taken of anonymous communications.*

G. F. B. (Gloucester).—*Your postcard has attention. We hope to give you the address in an early issue.*

W. A. S. (Birmingham.)—*The steam turbines are made by the Gustav de Lavals Augturbinfabrik, Stockholm. The necessary elastic flexure of the shaft is so small that no special means respecting the bearings have to be made. The flexure takes place only in one direction, and the stress does not change from + to − as in a shaft bent under a pull from a belt. Both the kinds you mention are subjects of patents. There is an outlet for air above exhaust.*

### SUBSCRIPTIONS.

The Engineer *can be had, by order, from any newsagent in town or country at the various railway stations; or it can, if preferred, be supplied direct from the office on the following terms (paid in advance):—*

| | |
|---|---|
| *Half-yearly (including double number)* .. .. | £0 14s. 6d. |
| *Yearly (including two double numbers)* .. .. | £1 9s. 0d. |

*If credit occur, an extra charge of two shillings and sixpence per annum will be made.* The Engineer *is registered for transmission abroad.*

*A complete set of* The Engineer *can be had on application.*

*In consequence of the reduction of postage on newspapers to one uniform rate for any destination outside the United Kingdom, Foreign Subscriptions will, until further notice, be received at the rates given below. Foreign Subscribers paying in advance at these rates will receive* The Engineer *weekly and post free. Subscriptions sent by Post-office Order must be accompanied by letter of advice to the Publisher.*

| | |
|---|---|
| Thin Paper Copies— | |
| *Half-yearly* .. | £0 18s. 0d. |
| *Yearly* .. | £1 16s. 0d. |
| Thick Paper Copies— | |
| *Half-yearly* .. | £1 0s. 8d. |
| *Yearly* .. | £2 0s. 6d. |

Reading Cases.—*The Publisher has in stock reading cases which will hold thirteen copies of* The Engineer. *Price 2s. 6d. each.*

### ADVERTISEMENTS.

*** *The charge for advertisements of four lines and under is three shillings, for every two lines afterwards one shilling and sixpence; odd lines are charged one shilling. The line averages seven words. When an advertisement measures an inch or more, the charge is ten shillings per inch. All single advertisements from the country must be accompanied by a Post-office Order in payment. Alternate Advertisements will be inserted with all practical regularity, but regularity cannot be guaranteed in any such case. All except weekly advertisements are taken subject to this condition.*

*Prices for Displayed Advertisements in "ordinary" and "special" positions will be sent on application.*

**Advertisements cannot be inserted unless delivered before Six o'clock on Thursday evening; and in consequence of the necessity for going to press early with a portion of the edition, ALTERATIONS to standing advertisements should arrive not later than Three o'clock on Wednesday afternoon in each week.**

*Letters relating to Advertisements and the Publishing Department of the paper are to be addressed to the Publisher, Mr. Sydney White; all other letters to be addressed to the Editor of* The Engineer.

### MEETINGS NEXT WEEK.

Geologists' Association.—Saturday, July 21st. Excursion to Guildford. Leave Waterloo 1.55 p.m. The geology is of five groups of the lower greensand formation.

# THE ENGINEER.

*JULY* 13, 1894.

### THE AMERICAN RAILWAY STRIKE.

The railway strike has assumed remarkable proportions during the past week. It has ceased indeed to be a strike in the proper sense, and has become something like a very important insurrection, capable, if rightly used, of teaching certain truths commonly overlooked. In a special sense, too, it is an experiment, and as such deserves to be watched with care. Chicago was in the possession of mobs who set all authority at defiance. They have already wrecked, burned, and destroyed property to the value of nearly £2,000,000. Nor is the mischief confined to Chicago. The insurrection has extended to California, and San Francisco was not in much better plight than Chicago. Pittsburgh was threatened, St. Louis was scarcely safe. Nor is the convulsion limited to railway men. The building trade and other businesses of various kinds are affected. What we see is a great social upheaval, and we may well ask ourself what it all means. For a long period demagogues, agitators, and semi-lunatics have in Europe and in the United States urged labour, so-called, to attack capital. They have not ceased to goad those who have nothing, to take from those who have something. These men have never ceased to tell their hearers and dupes that benefits of the choicest kind would follow on an open war. We now have war declared; a war on no small scale—war great enough to content our own Tower-hill ranters. Chicago was threatened with destruction. The railway yards were described on Monday as a "sea of fire." Matters are much better now, because the Government has asserted itself more strongly. In every direction the insurrectionists have expended their energies in destroying property. The destruction is worse than wanton; it is not only a crime, it is a blunder. The ruin of the railways means the future starvation of the destroyers. There are but two ways, it may be said, of accounting for the folly of the people: either they must have been seized with a mad frenzy of which history affords not a few examples, or the mischief is being done not by the railway hands, but by the thousands of idlers to be found in every city, who have nothing to lose by violence, and everything to gain by plunder. But we are not sure that either explanation will wholly cover the ground. In San Francisco we are told that the mass of the inhabitants side with the strikers. In Illinois the militia have refused to act. Hundreds of men of the mob are being drilled, and are prepared to fight. The Governor of one State remonstrated with the President of the United States because he sent Federal troops to put an end to turbulence and riot. Is there to be a civil war in the United States? Are the roughs and the labourers going to destroy the middle class? Is bourgeois America to be swept out of existence by the Irish, Germans, Italians, Slavs, and negroes? Is that really the programme of Mr. Debs and Mr. Sovereign? We cannot say. It is scarcely conceivable that the dispute between the Pullman Car Company and its operators is the sole cause of the insurrection. We are disposed to regard it as a spark which has set a forest on fire. Unless matters had been planned beforehand the conflagration could not have assumed its present magnificent proportions. If the great mass of the strikers were asked for what they were fighting, they could not say; in truth, there is no one tangible cause. It can scarcely be argued, we think, that the people of the United States have a quarrel with the railway companies. We cannot find that the companies grind down their servants in any exceptional way. Those who use the railways seem to be fairly content with the rates charged. The only fact lending force to the contention is the action of the people of San Francisco; why they should join with the strikers it is impossible to see, unless indeed they have some special grudge against the Pacific Railway. The siding of respectable folk with the rowdy element of a great city is a notable fact, whatever may be its cause.

We have said that the insurrection is a great experiment. We see the doctrines of the socialist and the anarchist carried into practice, for the first time, without a Government being concerned. The events are those which signalised the Red Terror. There is not a pin to choose between the incendiaries of Chicago and the Commune of Paris. But the people of France fought against a king first, and against a Government afterwards. Most of the mischief was in certain cases perpetrated by the savage element of the population. Probably that is true of the American insurrection, but the difference exists that the people in the United States are not attacking a Government. They are attacking the greatest civilising element the world has seen—the railways. We have, then, that war so long advocated in progress. And what do we see so far? That very largely it is an onslaught of labour on labour. Any attack on capital must be opposed to the interests of labour. To ruin Chicago is not the best means of supplying food and raiment to the poverty-stricken. To wreck the railways can scarcely promote the wellbeing of those who are employed in working them. But there is more than this. The strikers insisted in the first instance on stopping all railway traffic. This they propose to bring about by withdrawing from work. That was war on capital pure and simple, but there was no bloodshed, nor fires, nor shootings. But so long as that condition of affairs exists under which there are two candidates ready for every occupation which can only employ one, it is clear that the withdrawal, resignation, or striking of one set of individuals can inflict little inconvenience on the employer. It becomes necessary, therefore, for the striker to extend the range of his operations. He makes moral war, so to speak, on the capitalist, but he makes physical war on his fellow labourer. This is the second and inevitable result of the attack of labour on capital. The striker soon has his hands full. He has to fight capital; he has to fight his fellow workman, and in the ultimate end he has to fight the forces of the Government. At all events, that is what would happen in Europe. What may occur in the States remains to be seen. The most serious element in the whole affair is that no one knows what is really the cause of it. For what are the working public striking? Is it really a labour question of the normal kind, a common every day matter; or is it an insurrection of the foreign element in the United States against the Americans? We do not believe that the true meaning of the transactions which are taking place is fully realised in this country. History is always repeating itself, mainly because the springs of action alter little, if at all, as time passes. The same end is sought in all cases, only somewhat different means are employed. The log has to be hewn, but a different axe is employed. Our forefathers used one of flint or jade, we use one of steel; but steel or jade, still we hew. The American citizen—and we use the word in its limited not in its national sense—has for a considerable period engrossed the intellectual work of the United States; the manual work he has relegated to the alien and the stranger. It was just the same in old Rome. A Roman citizen never worked, he employed slaves; very largely the slaves were foreigners. In the United States just the same customs hold good, only the workpeople are not called slaves. The railway people who strike, and burn cars, and make mischief generally, are not American citizens of the better sort; they are, as we have said, Scandinavians and Irish and Italians. Are we to take the Chicago riots as a rebellion against the masters? Be this as it may, one thing is certain—it has been certain for a long time—and this thing is that the law has very little power over, and is very little in sympathy with, large sections of the American people. Take, for example, the scandalous and bloodthirsty lynchings that have disgraced the Southern States for years. To us living in a more civilised land, it seems that the one thing wanted just now in the States is a Government that can govern. Napoleon the First said that if he had been in power on a certain memorable morning, no French Revolution would have taken place. "I should simply," he said, "have swept the streets with grape shot first, and heard what the people had to complain of afterwards." It seems to us that, while grape shot is a great evil, a weak-kneed Government may be a still greater calamity for a nation.

### SUPERINTENDENTS OF GOVERNMENT FACTORIES.

After some delay, a Superintendent to the Royal Gun Factories has been appointed—namely, Captain Ingales, R.N. It was reported that Sir G. S. Clarke, R.E., had been appointed to Waltham Abbey; but this, it appears, is a mistake, so that the latter department is still without a Superintendent. The work is in each case very important, and calls for peculiar qualifications, which we trust have been secured in the case of the appointment already made. It may be objected that this officer has never been engaged in making guns, and that officers and civilians might have been found who have experience in such work. To this the natural reply would be that the number of such men is very limited, and that if the special qualifications called for are found in a higher degree outside that number, it may be right to choose accordingly. Time may be expected to show the wisdom of such selection; and from the tone we have adopted it may be inferred that our object is by no means to discuss the selection, or to make further remarks on individual officers than to note the fact that we understand that Captain Ingales has been engaged in organising the armaments, and has had experience and shown special ability, so that high expectations may be justified. Our object, however, is to keep clear of any individual selections, and to take this occasion to consider the general question of our Government manufacturing appointments. The problem of how to work for the best interests of the country is not an easy one. The issues at stake are enormous, involving the application of millions of money and the production of vast engines of war which become more powerful and complicated every year, and whose powers may hardly be fully tried in time of peace, and may only be suddenly called out when the safety of the kingdom depends on them. The root of the question, in our mind, lies in the difficulty of having a man at the head of all the departments possessing sufficient grasp of actual manufacturing matters to judge how each department is really doing its work, and who at the same time has the confidence of the country so completely as to have a free hand to take any step he thinks right. In past days we had, for years without number, superintendents working under Master-Generals, or directors with various titles, who were distinguished officers whose objects and principles were all that could be asked for, who were capable of judging how engines of war answered their purpose when brought to act, but who had no pretence to any knowledge as to the working of factories. They could not tell whether large sums were saved or wasted, or whether factories were well arranged with a view to putting forth the increased powers demanded in war time. Such questions were the business of the superintendents, who had, or were supposed to have, special manufacturing knowledge and experience. Now, without going further, it is clear that from a superintendent so placed much was expected. He was expected to watch the interests of the country, to plan with a view to efficiency and economy in every way like the head of a private factory, but to do so when he gained no profits himself, had no board of directors capable of appreciating his efforts, no rival firms to prove his success by comparison of results achieved, and lastly, no shareholders capable of judging whether they were obtaining a return for their capital invested. Can it be wondered at that in old days the "respective officers," as they were once called, or "Heads of Departments," were liable to be sleepy and conservative? Then came in the Armstrong rifled guns and *matériel* like a flood, and things woke up. In a few years, perhaps, on the principle that "new blood" was the great matter, came in the "five years'" system. As originally intended, we believe that this was not wholly bad; it was no bad thing to have the opportunity of getting rid of an indifferent or moderately good man as a matter of course after a limited trial, without heaping disgrace upon him and making a victim of him, but as a rigid rule it was injurious beyond conception. No officer, however good, could be kept on much beyond five years. How, then, could it be expected that a keen, earnest man would throw himself into the work of a factory, grapple with the details of all its branches, and then be satisfied to be sent off with the hope that after two years' soldiering he might be employed, not in the same department probably, but perhaps in another. Surely the best men would be just those who, having acquired the mastery and love of their work, would wish to keep to it. They were the men who would receive offers of employment from private factories, and would probably accept such offers directly that they found that they were not appreciated, and even if not disgusted and mortified in some way. If any one compares what is the position of Sir Andrew Noble or Colonel Dyer at Elswick, with that of the various superintendents whose services have been retained, the matter will be apparent. If it is urged that "Andrew Nobles" are not to be met with often, the reply is, that all the more reason that we should secure them when we get them, and not have private manufacturers like Armstrong and Whitworth, as it were, walking up when they please, and picking our best men. We can name more recent cases, but we purposely here keep to ancient history to illustrate principles as far as possible, without touching on matters where soreness may exist. The five years' system, however, had evils reaching far beyond what we have indicated above. It threw all manufacturing questions proper very much in the control of the subordinate but permanent manager, instead of the superintendent. We will take a case in point, and we could furnish actual names if we chose to do so. A certain department contained machinery which involved the supply of many thousand pounds worth a year to keep up the plant, to say nothing of furnaces and other features. The workmen employed on them were directly under the manager, who, though under the superintendent, was their permanent head. Can any one suppose that the most scientific and energetic superintendent, with a run of only five years, could possibly hold his own against the manager in such a position in such questions as the working of lathes, furnaces, &c. The manager had a salary of, say, £400 per annum. He was a man of such experience that he would probably command £1000 per annum in a private factory. If he remained in his position under Government, can it be doubted that he would be sorely tempted to accept money from contractors, to oil the machinery and make all go smoothly? As a matter of fact, certain managers and foremen have been discharged, as was inevitable, and the property they possessed is not to be accounted for except on one supposition.

Happily, we have in a measure emerged from the five years' system in its extreme form. Superintendents are not now, so it is said, to be necessarily limited as they were; nevertheless an evil remains that appears incidentally in what we have said above, namely, that we employ both superintendents and managers on salaries far too small for it to be reasonable to expect to retain the services of the best men of the high class that we require. At the present moment our departments are all under Dr. Anderson, the Director of Ordnance Factories. It must be satisfactory to superintendents to have to deal with a chief who understands manufacturing questions from long experience, and who can enter into difficulties, and appreciate manufacturing achievements. There is, from this point of view, much to be said for a civilian who has given his life from childhood to work which an officer can only have taken up at a comparatively mature age. This suggests the question that has come up in the press as to the desirability of appointing civilians instead of officers throughout. On this there is something to be said on both sides. The past life of the civilian, which has given him special manufacturing experience, has in many cases so connected him with manufacturing firms and interests as to make it difficult for him to stand in a position as free from prejudice and suspicion of interest as an officer generally stands. Then there is undoubtedly a great advantage in a man having a strong sense of the actual conditions under which all war *matériel* will be used on service. If this be not so, how comes it that large firms for war *matériel* so commonly secure the services of officers? Witness the recent appointment of Colonel English to Palmer's, and the earlier one of Capt. Tresidder to Brown's. Abroad it is held that the heads of English manufacturing departments are singularly free from corruption. This has been attributed to the high character borne by English officers. We, however, lay stress on the word English, and we believe that the same might be secured by Englishmen who are not officers, making, of course, a proper selection. We think, however, that officers, for the reasons given above, are naturally specially suited for work in war *matériel* factories, if well selected. With Sir A. Noble at the head of Elswick, there can be no question as to the possibility of an officer acquiring the desired manufacturing ability and experience, but they must be treated reasonably. A civilian who has been making, say, carriages, who was suddenly put in charge of a large powder factory, for five years only, and that on a very moderate salary, would hardly be expected to prove a great success. This is much what we have been doing with our officers. On the other hand, we trust that no feeling of corps jealousy may be allowed to come in. We observe that a naval officer is again appointed to the head of the gun factories. If this means that a naval officer is as a matter of course to have the appointment, we think it a most pernicious principle. The late superintendent, Captain Younghusband, R.N., was a singularly able man—in fact, an admirable man for the work. We trust that his successor will prove equally successful, and that it will turn out that the Navy have twice running shown that they have men with the best qualification that could be found. But surely when the importance of our ordnance is considered, and when all the difficulties we have passed through are remembered, no one will urge that when a vacancy occurs we can afford to pass by the best man, wherever he may be found, for the sake of keeping an appointment to any one branch of the service.

### RAILWAY AND STREET TRAFFIC.

In a recent article we brought under review the loss of life occurring on the railways of England and Wales, in comparison with the fatalities arising out of the ordinary road traffic. It appeared, according to the Registrar General's Report for 1892, which had just been issued, that whereas the number of persons killed by vehicles on English and Welsh railways in the year was 925, there were in the same period as many as 1321 persons killed by vehicles other than those of the railway. Adding to the latter the number of persons killed by horses, the fatalities of the road traffic were found to be 1549. It was also apparent that the deaths from the traffic of the London streets in 1892 amounted to more than twice the number of fatalities among railway passengers throughout the United Kingdom, even including those cases in which the latter were themselves more or less in fault. Concerning the vehicular traffic of the metropolis, the Registrar-General has lately given the particulars for 1893. The facts so recorded are remarkable, and lend yet further force to our remarks as to the relative danger of road and rail. Notwithstanding all the care taken by the London police in the regulation of the traffic, last year was eminently disastrous. As many as 304 deaths were caused by vehicles and horses in the streets of London, being 35 more than in 1892, and exceeding the corrected average by about 40. The Registrar-General considers it probable that the 304 deaths thus specifically returned "are far from representing the entire number caused in the streets by vehicles and horses," many deaths being registered under such indefinite headings as "fractures," &c. Comparing the fatalities of the street traffic with the growth of the population, we meet with some startling data in harmony with the statement of the Registrar-General as to an excess over the "corrected average." Thus in 1873 the deaths were one in 15,544 of the population. In 1876 the ratio was one in 16,305, and in 1883 it was one in 17,573. These eleven years therefore showed an improvement, the street "death-rate" undergoing a decline. But in 1893 the deaths became one in 14,165, a much less favourable ratio than that recorded twenty years earlier, and still worse in comparison with 1883. Of course the population varies from year to year, and there are considerable fluctuations. But the broad fact presents itself that between 1873 and 1893 the population of London has increased by rather less than 28 per cent., while the deaths from the street traffic have increased by 40 per cent. Had the intervention of the police undergone no development since 1873, we may ask, What would have been the result as affecting the number of fatal accidents? But a question may perhaps be raised as to whether the action of the police in this matter is not chiefly directed to prevent a block in the movement of the vehicles. If the police were withdrawn from the various centres where the lines of traffic cross each other, the effect would show itself in a frequent deadlock, all progress being for some time arrested. Traffic is now facilitated, but to what extent is it rendered safer? Looking at the figures we have cited, we should say, judging by results, that the danger is greater than ever. How is it that the heavy traffic is so fatal to human life? Vans, wagons, and drays caused more than a third of last year's deaths, and this is frequently their share of the slaughter. These vehicles are often driven at a rapid pace, and are not capable of being readily pulled up. Carts kill less than half as many as the heavier class, and cabs are about the same as the carts. On the whole, carts seem less fatal than in years gone by, and cabs are nearly in the same category. But the heavier or more cumbrous vehicles, which in 1873 killed seventy-nine persons, have slain more than a hundred in each of the last four years. Of course, these accidents are to a very large extent those in which persons are knocked down and run over. The pedestrians are the sufferers, and the practical question is how to enable them to traverse the streets with greater safety to themselves than is now the case. Their position might be worse than it is, but it seems to be getting no better.

### THE SCOTCH OIL TRADE.

Few industries have had a more chequered and interesting career than the Scotch mineral oil trade, and probably in none has continuous and severe competitive pressure been more determinedly met by steady advance in productive methods. It is therefore satisfactory to find that the recently published reports of the leading companies afford considerable ground for hope that the threatened extinction of the industry may be averted, and that the future even promises financial returns to those who have so long struggled against the competition of natural petroleum oils from abroad. The previous financial year was extremely bad; so bad in fact, that not one of the companies paid any dividend. This was mainly due to the breakdown of the combination of the companies with the Standard Oil Company of America, which led, in conjunction with other causes, to a depreciation in the value of products, as compared with 1891, of £200,000. Such an untoward state of affairs recalled the disastrous period between 1864 and 1872, when the appearance of American petroleum reduced the price of burning oils—then practically the only product of the Scotch trade—from shillings to pence per gallon, and nearly swept the home industry out of existence; the pioneer concern, Young's Company, Limited, being the only survivor of that early epoch. Since that time, however, the industry has been put on an entirely different footing by a long series of mechanical and chemical inventions, resulting in the extraction from the shale of a much greater value of products, accompanied by a vastly reduced cost of production. Though little has been done this year in the way of dividend paying, the position of all the leading companies is, as already indicated, considerably better than at the close of the preceding twelve months; and there are several circumstances rendering it probable that the improvement will be easily mantained, if not increased, next year. For one thing it seems probable that the bottom prices for burning and lubricating oils have, in the meantime, been touched, as it is well known that American and Russian refiners have been working for some time past at a loss, or at least without any appreciable profit. On the other hand, the cheapening of production, which has for many years been such a remarkable feature of the Scotch trade, still goes on, and several of the companies expect during the current year to make large savings in this direction. The high price obtaining for sulphate of ammonia, and the increasing use of the intermediate oils for gas enriching purposes, are also favourable to the prospects of the home industry. Legislation on the "flash-point" of burning oils used throughout the United Kingdom, which may reasonably be hoped for, would also tell in favour of the Scotch trade, though perhaps not to the extent expected by some. It is an indisputable fact that large quantities of lamp oil are sent to this country from America which could not be legally sold there; and it is equally indisputable that these low flash oils are largely to blame for the terrible frequency of lamp accidents in England. In Scotland, where the native article is still almost exclusively used for burning purposes, such catastrophes are comparatively unknown. The capital at present invested in the Scottish oil industry is about £3,000,000, and last year over 1,180,000 tons of shale were mined and distilled, producing 45,000,000 gallons of crude oil. From this were obtained 27,000,000 gallons of burning, lubricating, and gas oils and naphtha; 20,000 tons of solid paraffin for candle making; and about 30,000 tons of sulphate of ammonia, the production of the latter article of commerce having now become a highly important branch of the trade. The industry gives employment to many thousands of workpeople, and in all its branches affords ample scope for the improvements of the engineer and chemist, so that on all grounds its improving prospects must be considered a matter for congratulation.

### A TRUCE IN THE COALFIELDS.

Coal affairs in the Midlands have suddenly assumed a most interesting aspect—an aspect fruitful of promise for a two years' truce in the coalfield. Some time ago it was stated that the employers intended to ask the Conciliation Board for a reduction of 10 per cent. in wages. This statement was vigorously denied on behalf of the coalowners. One of them, holding a most influential position in South Yorkshire, volunteered a statement that an application had been made, but that the terms of it were simply "to vary the rate of wages." He said the coalowners would have nothing to do with 10 per cent., or any definite figure, and alleged that Mr. Pickard was anxious to put 10 per cent. in their mouths. The position of the coalowners, it is added, was to go before the Conciliation Board and Lord Shand, produce their figures, and ask them to decide what amount the reduction should be. It now appears certain, however, in spite of what this coalowner said, that 10 per cent. is to be the figure applied for. What is called an informal meeting of the Conciliation Board has been held, at which the proposal takes this form: that the minimum wage shall for two years be 30 per cent. above the prices which ruled in 1888; the men to be asked to submit to a 10 per cent. reduction on the 1st of August next, and wages to remain at that figure until the 1st of January, 1896; from January 1st to August 1st, 1896, wages to be allowed to go up as high as 45 per cent. over the amount paid in 1888, if trade improve sufficiently to justify the miners' demands. These proposals, it will be seen, cover the principle of a maximum and minimum wage. That there is something in them, was evident from the result of inquiries made both amongst coalowners and miners' leaders. They are now confirmed, Mr. Benjamin Pickard, M.P., President of the Miners' Federation of Great Britain, stated at Barnsley, on Monday night, "that he had no hesitation in saying that in his judgment, after the arrangement was consummated, the best interests of both owners and workmen would be accomplished." He did not say expressly that such an arrangement has been made, but he distinctly left it to be understood that it had been proposed, and would come before the forthcoming meeting of the Conciliation Board next week. Now the exact forms of a provisional agreement to that effect are published, the proposal, if acceptable to the coalowners, will certainly be endorsed by the men, for it contains the principle, for which the miners' leaders have steadily contended, under the title of "a living wage." Mr. Pickard, in his unusually peaceful utterance, declared that "the hope of all the leaders was that a permanent settlement would be effected, and that the two years' truce, with a minimum wage realised, would secure for the future a stability in the trade for which they had all hoped for generations in the past. The gist of the proposal will be this:—All the advances, amounting to 40 per cent., secured by the miners' leaders from 1887 until 1891, would be permanently retained, with the exception of the 10 per cent. now conceded. The wages with that reduction would be definitely declared to be the lowest point to which mining remuneration should fall. On the other hand, if trade improves sufficiently to warrant an upward movement, the 10 per cent. will be given back and 5 per cent. added, making 45 per cent. above the 1888 rates, which would thus form the maximum.

### RUSSIAN "SECRET PROCESS" SHOT.

The further trial of the special Russian projectiles took place on July 6th, as reported in the daily 'papers. The general result up to this date is reported to be that the projectiles perforated the 6in. plates at an angle of 20 deg. from the normal, that is, 70 deg. with the plate face, but were broken up at 25 deg. with the normal, or 65 deg. with the plate. On July 6th, however, one shot was stopped and pulverised by Cammell's plate at 20 deg. of obliquity, with a penetration of only 2·3in., while on the other hand, one passed right through Brown's plate and backing at 25 deg. With regard to these results, it will be readily understood that if the "Russian secret" consists in the application of some false point to save the real point of the projectile from the sudden fracture which causes its defeat by the treated plates, there would be liability to uncertainty, for the least departure from truth in direction, or the least accidental irregularity in attachment of point, might cause failure, so that too much stress must not be laid on the variation in the results above reported. The persistent trial at oblique angles of incidence points, we think, to some device which is known to call for such proof to establish its character, though perhaps we may learn something to contradict this supposition from those who witnessed the trials on their return to this country. The actual theoretical effects of the oblique angles of incidence are as follows:—For the shot striking the 6in. plate with a velocity of 1850 foot-seconds, the perforations through steel would be—direct 10·32in.; at 10 deg., 10·30in.; at 20 deg., 9·70in.; and at 25 deg., 9·35in. For the projectile striking the 10in. plate with a velocity of 2400 foot-seconds, the perforations through steel are—direct 13·69in.; at 10 deg., 13·48in.; at 20 deg., 12·89in.; and at 25 deg., 12·41in. It appears, then, that results calculated on the supposition that steel behaves itself with the ever reliable action of wrought iron is misleading, as indeed would have been expected, especially in the case of treated plates. We would call attention to the fact that the Russians do not appear to have tested the comparative behaviour of treated and untreated steel plates attacked obliquely, although this is an important and almost untried experiment, and one that concerns a Power that has not decided which to adopt. The only oblique firing that comes to our knowledge is the test of this Russian device, which appears to be considered specially important, and such as to call for special trial at oblique angles.

## LITERATURE.

*La Flotte de Guerre*. By M. EMILE WEYL. Paris: E. Plon, Nourrit et Cie. 1894.

THIS spirited production, by M. E. Weyl, upon the present position of the French Navy should compel a special interest in the mind of every British subject, as, from beginning to end, it is practically a comparison of the naval resources of the United Kingdom with those of our neighbours across the Channel. At the same time it affords much valuable information as to the advantages and disadvantages of the system pursued in France for carrying on the construction, the maintenance, and the manning of her fleets; there being, moreover, food for reflection for ourselves in a consideration of the same.

The work comprises a number of chapters, each dealing with a specific subject, such as the ministry of marine affairs, the officers of the Navy, the technical *personnel*, the arsenals, and naval construction; finally, with the fleet itself, distributed into three classes, ironclads, cruisers, and the torpedo flotilla. Part of the matter contained in these chapters has already appeared in a series of articles in the *Journal des Débats*, but an important appendix has been added. Not the least interesting feature of this appendix is the original *procés-verbal officiel* of the experimental committee, which was delegated from the Admiralty Board of France, in March last, to witness trials with the Magenta, in order to ascertain whether her angle of heel, with the helm put hard over, whilst the ship was running at full speed, was likely to compromise her stability. The trials were instructive, and appear to have been conducted with the utmost fairness and impartiality.

The Magenta was only ordered to hold herself in readiness on the eve of the day appointed for the tests to be applied. The ship's own company worked the engines and occupied the stokeholds, also training and working the guns. Whilst running at a speed of sixteen knots, the heavy 34 cm. (13¼in.) guns being trained axially, the helm was suddenly put hard a-port, the result being an initial inclination of 9 deg. from the vertical at the moment of careening, the vessel afterwards partially recovering and remaining at a permanent angle of heel of 7 deg. 30 min. during the rest of the turn. Afterwards a second and third experiment was made, with two or more of the heavy guns trained abeam. With three guns thus trained simultaneously on the port beam, and hence of course favouring the inclination of the vessel, the list—with the helm put, as before, suddenly hard over—was at first 14 deg., subsequently remaining at 13 deg. Whilst the ship was in this position, it was ascertained that the guns could be trained round with the utmost facility, the hydraulic gear not being affected by the heel. The experiments were then discontinued, as fears were expressed of the possibility of some of the boiler tubes being too long uncovered, when the ship lay over permanently to this angle. Enough, however, had been done to satisfy the Committee that there was "not a shade of apprehension for the stability of the ship;" and in this conclusion we fully concur. At the same time it is only fair to remark, in justice to those who so severely condemned the Magenta upon her completion, that one glance at her ponderous superstructure—which stretches like a steel screen from mast to mast—shows how terribly handicapped this battleship would be, in a heavy sea, with wind on the beam.

Monsieur Weyl criticises sharply the arrangements made in France for the design and construction of ships of war, both in the Government shipyards and by the trade. In the first place, he objects to a system that leaves, not only the design, but the carrying out of the same—without any control of sea-going officers—practically in the hands of naval engineer architects, whose duties are so laborious and incessant that they never have time or opportunity to proceed afloat, in order to observe the behaviour of the vessels which their genius has created. Here he testifies to the wisdom of the plan adopted by the department of naval construction in Great Britain, pointing out that even the head of that branch can find time to make occasional voyages in his own battleships and cruisers. As he justly remarks:—"Observations on the vessel itself are of infinitely greater value than observations on the plans. In the next place he deprecates the delay and folly of the system by which designs are modified and mutilated between the constructive departments at the various ports and headquarters, entailing, he assures us, a loss of time sometimes extending to six months, before the drawings are subsequently approved, and as often a loss of many valuable features belonging to the original idea. He finds fault also with the absurdity of the plan which makes the officers of the marine artillery responsible for the design and manufacture of weapons for naval warfare, with which they have not in the course of their legitimate military duties any subsequent association.

But perhaps the portion of this work which possesses the greatest interest in our eyes is the comparison which M. Weyl has drawn between the actual and prospective conditions of the French navy, as assumed to exist by the Whitehall authorities, and those which he asserts do really obtain. The only battleships and coastguard ironclads which he recognises as forming part and parcel of the effective and prospective French navy are as follows. In the service:—Amiral Baudin, Formidable, Amiral Duperré, Hoche, Magenta, Marceau, Neptune, Courbet, Devastation, Redoubtable, Caïman, Indomptable, Requin, Terrible, Fulminant, Furieux, Tonnere, Tennant, Tempête, Vengeur. Completing:—Brennus, Jemmapes, Valmy, Bouvines, Trêhouart, Charles Martel, Jaurréguiberry. On the stocks:—Lazare-Carnot, Bouvet, Masséna, Charlemagne, Saint - Louis, comprising thirty-two vessels.

Six other ironclads of an early date and five armoured cruisers are of wood, and will disappear from the navy list very shortly. The Friedland and two remaining armoured cruisers will probably share the same fate. Two or three insignificant wooden ships may be added to this category. Hence M. E. Weyl, who should be in a position to realise the condition of the French fleet, only accredits to it—even at the expiration of the century—a prospective strength of thirty-two battleships and coastguard ironclads, and it is with unfeigned astonishment that he finds in our Admiralty returns no less than fifty-one ironclads of sorts asserted to be afloat or building. He expresses it thus:—"C'est donc une masse de 51 bâtiments que nos voisins d'outre manche nous accordent pour la fin du siècle; en comptant largement, nous n'en trouvons cependant que 32. Cela donne une idée de la façon dont on dresse les tableaux comparatifs; le document parlementaire Anglais comptait parmi nos cuirassés tout navire portant une armure, sans s'inquiéter de l'âge, du système de construction—bois ou métal—des qualités de navigabilité! Un tel procédé n'a rien de scientifique . . ." The probability is that some confusion has arisen in the classification. We observe, for instance, that M. Weyl places the Dupuy-de-Lôme amongst the ordinary cruisers and not amongst the "cuirassés." As, however, we have over and over again maintained in these columns, no system is satisfactory which, as in the Admiralty returns alluded to, divides the ships into classes without giving their names. No two experts agree as to classification, and a nominal roll, such as that given by M. Weyl, is the only clear exponent of strength.

As to the French resources in cruisers built and building, he is equally at loggerheads with our Admiralty figures. Although the return already alluded to, gives seventy cruisers as forming the prospective strength in these classes of the navies of France in three years' time, M. Weyl is unable to make a computation of over forty-four, including twenty-five already in the service, seven now completing afloat, and twelve which are upon the stocks. It is a matter of congratulation to us, however, that the mistake, as in the case of the ironclads, appears to have been made on the right side, and we are happy in finding ourselves richer than we anticipated—rather than poorer.

In speaking of the French arsenals, dockyards, and anchorages for fleets, M. Weyl takes occasion to mention the very exposed position of some of the latter, as liable to torpedo boat attacks, and in most cases to bombardment from the enemy. He points out the defenceless condition of Cherbourg at the present moment in this respect, and states that the works now in progress are undertaken with a view of protecting the anchorage from danger of this nature. It is impossible not to find in these remarks a word of warning to our authorities. At Portsmouth and Portland we understand that arrangements for securing a protected anchorage are already in progress. Much, however, remains to be done elsewhere.

*Odontics, or the Theory and Practice of the Teeth of Gears.* By George B. Grant. London: Sampson, Low, Marston, and Company.

## THE ANTWERP EXHIBITION.

(*From our Special Commissioner.*)

PROBABLY no International Exhibition is ever quite finished until the time for closing it arrives. Objects damaged in transit have to be replaced, or exhibitors take up vacant spaces in their vicinity, so that workmen are still to be found during the morning in various parts of the building. Still, these are so few that the Exhibition may now be considered in full working order. In two respects the Machinery Hall is far superior to the main building. As will be seen by the plan on p. 325, April 20th, the passages are wide and straight, whilst in the Industrial Hall the commissioners of some of the foreign sections seem to have tried to construct a maze. The gallery along one side of the Machinery Hall is very convenient, as it enables visitors who are looking for a particular exhibit to see it from above, and to go straight to it. In the Machinery Hall, Farcot's Ventilators, which were illustrated in THE ENGINEER of April 20th, are working very satisfactorily; but in the main building there is a want of air, as the high erections obstruct the circulation, and the awnings prevent the ventilators in the roof from being of much use.

Two of the railway companies in the British Section have made additions to their exhibits since I described them at the end of May. The Lancashire and Yorkshire show a rail fitted with Messrs. Aspinall and Hoy's patent "Electric Lever Treadle Contact" arrangements. The pin, pressed down by the flange of a passing wheel, is connected with a small signal post, so that the operation of the apparatus can be clearly seen.

The South-Eastern Railway has added some more photographs of places of interest on its line; and it also shows a "train describer," by which one signal station informs the next the place from which the train then passing has started. Besides this, it has the apparatus for electric communication between passengers, guards, and driver; and a model of Sykes' block system, practically the same as one of those already described in the London, Chatham, and Dover Railway exhibit.

A stamp mill for crushing gold quartz has now been in operation for a week, and is attracting a good deal of attention. It has been made at the Erith works of Messrs. Fraser and Chalmers, of Chicago, and it forms part of the exhibit of the Transvaal Republic. The material treated is brought from different mines in the Transvaal; they have altogether 150 tons of quartz, and are at present working an hour per day, from 3 to 4 p.m. The chief novelty in this mill is in the method of feeding. A new arrangement of the "Automatic Challenge Feeder" has been adopted, in which the whole of the feed apparatus is hung on iron bars, running from the battery-posts to the framework of the ore-bin, instead of standing on a separate wooden frame. In the Challenge feeder, the ore falls from the bin on to a circular revolving table. An arm from the central stamp of the battery works a lever, which causes this table to turn, so that the delivery of ore is always proportioned to the speed of the battery, which is here set for 92 blows per minute. The ore is crushed wet in the usual manner, and then falls on to an amalgamated copper plate, 12ft. long by 5ft. wide, and set at an angle of 1¾in. to the foot. In the Transvaal, the fall is usually rather less; but here it has been increased as an experiment. The mercury on the copper plate takes up the free gold in the mixture, and the remainder passes through troughs on to two "Frue-vanners." These consist of revolving endless bands of india-rubber ⅛in. thick, with edges turned up an inch. The length of the level upper surface is 13ft., and the slack is taken up underneath by adjustable rollers, in the same manner as with cable car motors. An arrangement at the upper end causes the material to be equally distributed over the surface of the india-rubber, which is caused to travel slowly upwards, and at the same time to oscillate, so that the heavy portions, consisting chiefly of gold mixed with iron pyrites, are carried forward, whilst the slimes flow down the table into a settling reservoir at the end. The concentrates will be sent to England for treatment, probably also the slimes, if they are found to contain sufficient gold to make it worth while; but the free gold from the amalgamating table will be retorted at the Exhibition. In the Transvaal the concentrates are either first roasted and then treated by the chlorination process, or else the gold is extracted by the cyanide process, which is said to give very satisfactory results in that country.

In an adjoining building is the general exhibit of the Transvaal Republic, which has been ready since the opening of the Exhibition; though I thought it better to reserve any mention of it till Messrs. Fraser and Chalmers had the quartz mill in working order. In the entrance hall are pyramids representing the annual gold export of the country. These are exhibited by the Chamber of Commerce of Johannisberg, and range from 230,189 oz. in 1888 to 1,478,114 oz. in 1893. There are also several other examples of the mineral production of the country, such as coal from different mines, a large block of silver-bearing galena, &c. In the hall on the left are chiefly agricultural products, such as grain and tobacco. There are also good samples of ostrich feathers and ivory, a little timber, and some native curiosities. On the right of the main entrance the exhibits are almost exclusively mineral.

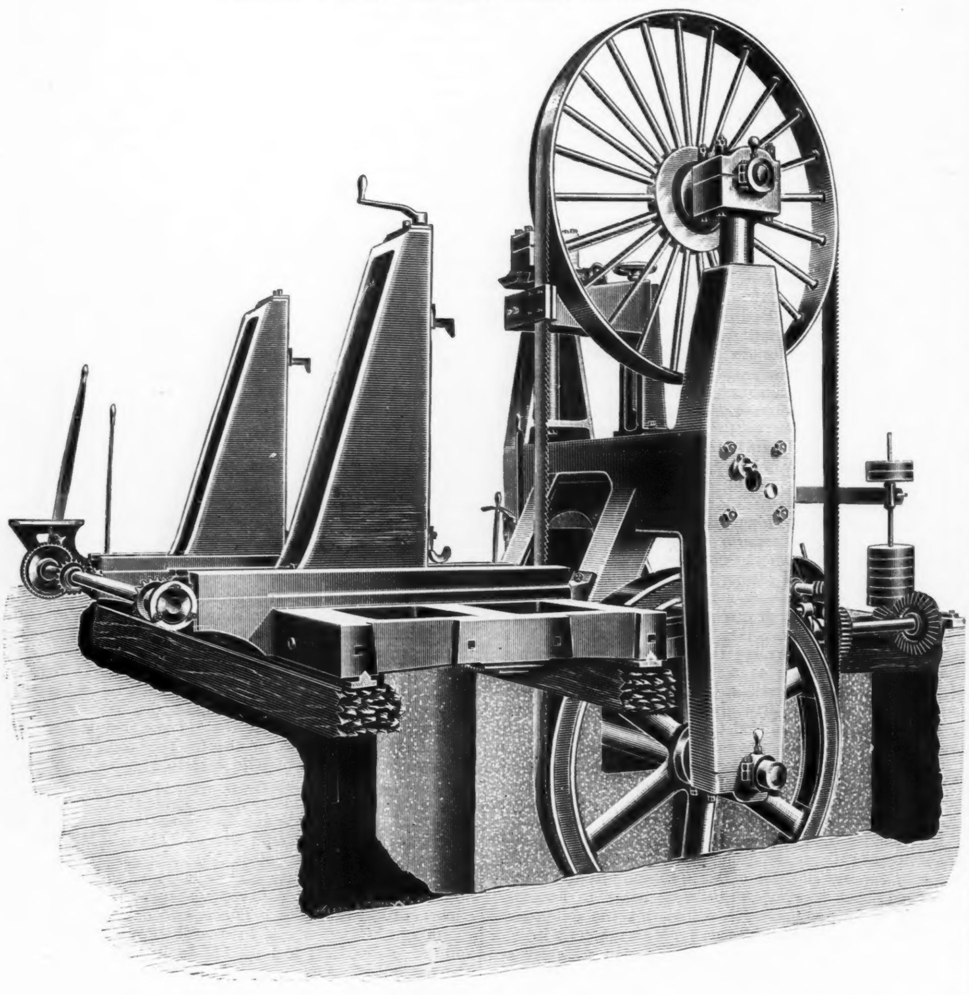
The most interesting is probably a complete section of the Witwaterstrand lode near Johannisberg, with samples taken every few yards along the entire length of the lode. Specimens of various descriptions of gold-bearing quartz, of antimony ore, and of various descriptions of galena, are also shown; but these lose much of their value from the fact that no assay of any of the exhibits has been furnished, and that the explanation on the specimens has only been given in Dutch. The Transvaal Exhibition is so remarkably good, and so well arranged, that a little additional information would be of great value to anyone desiring to study the mineral resources of the country. To take one important branch—the galenas. These are, as far as can be judged by appearance, very free from zinc, and therefore very suitable for smelting; but as appearances are often deceptive, an assay giving the lead, zinc, silver, and perhaps gold contents of each sample would be most useful. A good many specimens of coal are also shown, mostly of poor quality, as is generally the case in the upper seams of a mine. Another very interesting exhibit in the same room is part of the core of a boring put down with a diamond drill at the Witwaterstrand, to the depth of 2442ft. By this they see that they have ore enough in view for another hundred years, at the present rate of working.

The plans of the railway to Johannisberg are also shown. The line commences at Komati Poort, on the Komati River, where it joins the Pretoria and Delagoa Bay Railway, and goes to Leijdsdorp, on the Murchison Range, a distance of 225 miles.

Another interesting exhibit in the grounds is called "The American Gold Mine." It is a model—to the scale of ¼in. to the foot—of the first and bottom levels of the Saratoga Mines, in the State of Colorado, near Denver. Country, rock and ore are in their proper positions, to scale; miners work in the shafts or in stoping, ore trucks run, buckets ascend, and the pump rods rise and fall—in short, the whole work of the mine may be seen at a glance. In the Saratoga Mines the tunnels are run under the ore deposit, and the miners work upwards, timbering where necessary. The scenery on the surface is a good representation of that part of the Rocky Mountain district; and pumping engines, winding engines, and air compressors are all shown to scale. A train of donkeys conveys stores up a mountain path, and a stamp mill—like the one exhibited by the Transvaal—is working in one corner. A Halliday "ropeway" conveys the ore from the pit head to the stamp mill, which is driven by a water wheel. Between the mines and surface there are figures of eighty men at work, and the model is altogether more complete than anything of the sort that I have seen previously.

## LARGE LOG BAND SAW

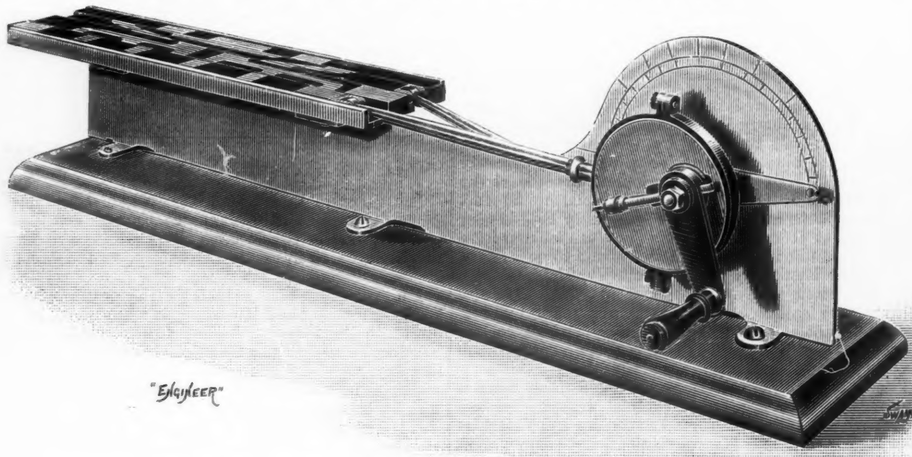
MESSRS. J. PICKLES AND SON, HEBDEN BRIDGE, ENGINEERS



### LARGE LOG BAND SAW.

THE above illustration represents a new design of large band saw with travelling table for the conversion of large logs, either by squaring or opening them through the middle and quartering, or by sawing them into flitches and boards. It is a substantially-built machine, and possesses the necessary features for ensuring truth and facility in manipulation. The main standard is massive so as to withstand the heaviest stresses. The top pulley is of wrought iron, lightly built, while the bottom or driving pulley is very heavy, as it has to act as a fly-wheel. When the machine is stopped there is no back-lash, and the lessened tension on the saw is on the side which is not cutting. Thin saws are used, and both pulleys are so constructed as not to require any covering, the teeth being free from the periphery. Adjustment is provided for the maintenance of the proper position of the saw blade without affecting its set. There is a sensitive tension arrangement allowing freedom for expansion and contraction of the saw, under the restraint of an adjustably-weighted lever. The saw guides are of simple form, and adjustable as to position, as will be seen from the engraving. The travelling carriage is of substantial construction, with screw dogs to hold the log, and is provided with a sliding movement actuated by screws with the bevel gear and ratchet lever shown, to advance the timber to the saw after each successive cut. There is also a simple set-off motion actuated by a lever for withdrawing the log clear of the saw for the return motion. The travelling table is fitted with pulleys and shafting, running upon iron rails fixed to longitudinal timbers, the feed motion being variable by cone pulley, worm, and spur gear. It is also fitted with quick return motion. It is made in nine different sizes, with saw pulleys varying in diameter between 6ft. and 8ft., requiring between 10 and 25-horse power. It is manufactured by Messrs. John Pickles and Son, Hebden Bridge.

## WILKINSON'S VALVOMETER



### WILKINSON'S VALVOMETER.

BY means of this instrument valves and valve motions in steam and other engines can be set out to actual size, and the points of admission, cut-off, exhaust and compression of steam be determined by simple inspection. The instrument is constructed with two slide bars on which the port openings corresponding to the valves are scribed full size. The bars move in slots, the intermediate spaces having scribed on them the port openings in the cylinder and plate. Any form of valve, straight-ported, D-ported, Trick or piston valve can be set out on the bars to full scale. The travel of each bar can be quickly and accurately adjusted by the following means:—On one side, controlling the expansion valve, is an excentric of which the sheave can be adjusted to any given throw or degree of excentricity with the crank, and on the other, controlling the main valve is a slotted crank in which the throw can be adjusted by shifting the pin in the slot. The lead of each valve, or its angle of advance on the crank, can be adjusted separately to any given amount. All adjustments can be measured accurately by a scale of sixteenths marked on the instrument, and the angles of advance and positions of pistons in the cylinder read off on crank circle. The crank can be set to the back or forward centre for observing the lead, or turned to any position for observing the points of cut-off, exhaust and compression. The action of the steam engine governor in making a late or early cut-off according to the lead is readily shown. in all positions of the governor and link; and having two sliding bars, the instrument shows the modern automatic expansion valve and main valve with intermediate plate. The action of the governor and link motion in cutting off steam earlier is shown by shifting the lead of the excentric backward through a given angle and shortening the throw. By changing the lead of the main valve 120 deg. the action of the valve in reversing an engine is readily seen, and all intermediate positions show the effect of notching up by the lever and link. The ports on the valves can be altered to any desired inside or outside lap and any combinations between width and position of ports, and travel and lead of valves set out, and their effects studied.

The instrument is of service in the drawing office for designing valve motions and dimensions, and in the erecting shop, for setting and re-setting valves. It is further of great use when through local conditions, such as change of initial or back pressure, the valves of an engine have to be altered, or where valves have to be adapted. Being provided with means of demonstrating and measuring the effect of any of the above combinations, the instrument is valuable for the use of professors of engineering in demonstrating valve actions in steam and other engines to engineering classes.

The apparatus was designed by Mr. H. D. Wilkinson, M.I.E.E., of Mildmay-road. It is manufactured by Messrs. Nalder Brothers, Red Lion-street, London, E.C.

## A NEW INCANDESCENT LIGHT.

GAS and oil users will be interested to hear of a means of improving their light which is both cheap and simple. It is called an "Incandescer," and consists of a small pellet of some refractory material, the composition of which is not, of course, made known—costing very little, and able to last over a year with absolutely no care or cleaning. It appears to be a chemical composition, the ingredients of which, when passed through a heating process, form a hard solid stick, and when shaped into the desired form according to its intended adaptability, either for gas or mineral oil lamps, is practically unbreakable. Figs. 1, 2, and 3, show three methods of using it. Fig. 1 shows its application to an ordinary Argand burner, which is sufficiently clear without explanation. Figs. 2 and 3 show its adaptability to central button and ordinary round-wick oil lamps.

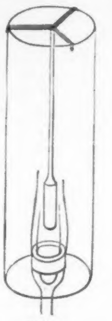


FIG 1

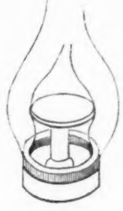

FIG. 2

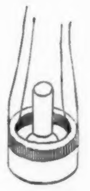

FIG. 3

In its present form it is most suited for use in burners with round flames—the results of its application to flat-wick lamps not being so far determined—although we see no reason why it should not be equally successful with the one as with the other.

The "Incandescer" has been photometrically tested, and the company intend issuing a circular containing a full report of the tests. We have at present to content ourselves with their assurance that it increases the illuminating power of a paraffin lamp by over 40 per cent., and decreases the consumption of oil 33 per cent. Another advantage claimed is the perfect consumption of the carbon, so that ceilings, pictures, &c., are not affected thereby. We, of course, cannot give the why and wherefore of the effect. Even if we knew the composition of the "Incandescer," we would certainly hesitate to lay down a theory, any more than we could explain why *any* substance on being placed in a gas or oil flame causes an increase of its luminosity—a thing which no chemist has ever yet satisfactorily explained. We wonder if the inventor of the "Incandescer"—Mr. L. Chandor, of St. Petersburg—himself could explain it? The "Incandescer" is being introduced in this country by the New Incandescent Light Company, 20, Bucklersbury, E.C.

## RICHMOND'S AUTOMATIC WATER ECONOMISER FOR HYDRAULIC LIFTS AND CRANES.

OF late years much attention has been directed to perfecting hydraulic lifts and cranes, as a result of the increased demand for these labour-saving machines which has sprung up since the adoption in many large towns of the system of supplying water at high pressures from a central pumping station. The improvements have mainly taken the direction of obtaining greater safety, increased smoothness of working, and more complete control over the moving parts. In these points it is improbable that the hydraulic lifts and cranes as now manufactured by firms who make a speciality of this class of engineering, will be much improved upon, but there is still one feature which, up to the present time, has not received the attention which its importance deserves, and that is the comparative consumption of water. As at present constructed, the majority of hydraulic machines use as much water to raise a light load—or in the case of a crane to return the unloaded chain and ball—as would be required to lift the maximum weight which the machine is constructed to raise. An exception to this, however, we illustrated and described in a recent issue. As water is paid for by meter at per 1000 gallons, it is a very important consideration that the consumption should be reduced to a minimum.

A machine which will automatically regulate the quantity of water to the work to be done, and be entirely beyond the power of the attendant in charge to alter, and yet simple in construction, cheap in first cost, and not liable to get out of order, has been a desideratum. A machine complying with these requirements is illustrated on page 39. It has been designed by Mr. R. F. Carey, and Messrs. Joseph Rich-

"THE ENGINEER"

SWAIN ENG.

mond and Co., Hatton Garden, have reduced the idea to practice, with, we are informed, most satisfactory results, by a series of experiments which have been carried out at their works at Bow in the following manner:—A two power hydraulic lift on the suspended principle was erected, fitted with the new automatic gear, and the whole was worked from a small hydraulic plant giving a constant pressure of 700 lb. per square inch, in order that the same conditions might be observed as if the machine were worked from the London Hydraulic Power Company's mains. Exhaustive trials were then made, first with a lift having a cage, and afterwards with a crane. The result of these trials proved so satisfactory in every way that Messrs. Richmond and Co. are now prepared to place these machines on the market, guaranteeing them to meet the required conditions, either at a fixed first cost or on a rental charge proportional to the saving effected.

Referring to the drawings, Fig. 1 shows the general arrangement of a two power lift, such as the experiments were made with. Fig. 2 shows the valve and pipe arrangement in section to a larger scale. The expander or multiplying machine is one of Richmond's long stroke jiggers—Carey's patent—the lifting area in which is divided between two small rams, which are arranged in a compact manner under the top sheaves. The two rams, which are connected to a cast iron crosshead, work vertically downwards, and act as a counter balance weight for the cage. This crosshead is provided with four long Babbitt's metal bushes, which work on turned wrought iron guides, which also form the framing on which the machine is carried. A tie or tension rod is connected to the crosshead and passes up between the two cylinders, and is connected to a wrought iron sling carrying the multiplying sheaves. The arrangement of the pipes and valves is shown so clearly on the drawing that further description is needless. The action is as follows:—To ascend, the starting valve is moved to the right, which admits pressure water through pipe X to an automatic valve, from the top port of which it passes to cylinder A direct, and from the bottom port to cylinder B. At the same time pressure water is turned through pipe Y by means of a pilot valve working in connection with the starting valve to an annular space above the automatic valve. In the case of only a light load to be raised the pressure from the cylinders A and B, acting on the piston of the automatic valve, is not enough to overcome the pressure on the annular space above it. The piston is therefore forced down, and closes the valve of cylinder B from the pressure, leaving the cylinder A open to pressure, and which is sufficient to raise the load. Directly the lift is stopped the annular space above the automatic valve is opened to exhaust by means of the pilot valve, and the pressure from the cylinders forces the valve back to its normal or open condition. The lowering takes place by opening the starting valve to exhaust in the usual way. In the event of a heavy load being raised, the total pressure on the annular space above the automatic valve is not sufficient to close it against the pressure from the cylinders due to the load, consequently both cylinders remain open to pressure and the maximum quantity of water is used.

From recent tests made it was found that a load of 4½ cwt.—or less—was lifted by the ram A only, and the quantity of water was 2·45 gallons, and with the machine exerting its full power a load of 12½ cwt. was raised through a similar height, the consumption of water being 4·65 gallons. Fig. 3 shows the invention as applied to a crane, the machine being one of triple power, and the valve gear for controlling it in detail. Fig. 4, it will be seen, is similar to the valve gear before described, with the exception that the automatic valve is duplicated to suit the additional cylinder, and in a similar manner the automatic valve can be multiplied to suit any number of powers. Fig. 5 shows a direct-acting balanced lift fitted with the economising gear, for which the arrangement of the valves is the same as already described. There must, we should think, be a large field open for alteration of existing lifts, and Messrs. Richmond and Co. anticipate a considerable demand for these machines when the principle and advantages become generally known.

---

TRIAL TRIP OF THE CHARYBDIS. — H.M.S. Charybdis, the latest and largest of the second-class cruisers for the British Navy, has just undergone her official steam trials at the mouth of the Thames with most satisfactory results. She is a ship of 4360 tons displacement, armed with ten guns, and differs from the Apollo class in having an additional upper deck sheltering her main armament and providing superior accommodation for her crew. On her natural draught trial, with an indicated horse-power of 7109, a speed of 19·3 knots was attained, and with 9136 indicated horse-power on the forced draught trial a speed of 20·5 knots, equivalent to nearly 24 statute miles per hour. This is the highest speed achieved with this class of vessel, and is eminently gratifying, as the horse-power in both cases was in excess of the contract, and the machinery worked in a highly creditable manner throughout. The ship has been built at Sheerness Dockyard, and the whole of the machinery has been designed, constructed, and fitted on board by Earle's Shipbuilding and Engineering Company, of Hull, who have now engined five of these second-class cruisers.

THE LATEST POLAR EXPEDITION. — The Windward, lying in Shadwell Basin, has been a subject of considerable interest. The work of shipping the aluminium launch, the sledges, huts, clothing, and stores of food, went on rapidly and without cessation, but the outsides of cases and barrels were most in evidence, and there was little or no opportunity of inspecting details, except as to open articles, such as the Berthon boats, the snow shoes, and the birchwood canoes. This vessel—which carries the Harmsworth-Jackson Expedition—is a stalwart wooden barque, originally a whaler, but strengthened considerably for her present purpose, and very complete in all requirements, from her iron-plated bows to the "crow's nest" hoisted up to the pinnacle of her maintop-gallant mast, and intended for the ice-master's anxious look-out. The land party of eight and the scientific investigators have their cabin in the afterpart of the hull, and their sleeping berths are in contiguity. Special provision is made for the meteorological and astronomical instruments. The former are furnished by the Royal Meteorological Society, and the latter by Mr. Cary, the Admiralty instrument maker. Amongst them a fine 6in. refractor telescope, said to be the largest ever yet taken to the Arctic regions. The ship carries a good spread of sail, and is reputed to be capable of accomplishing twelve miles an hour under canvas, when the circumstances are favourable. She is also supplied with auxiliary steam screw power. The *Standard* says that the crew will consist of twenty-two men, many of them of long experience in the northern regions. They are housed in the forecastle, which has been made as comfortable for them as could be practically done. The lighting, heating, and ventilation have been also as well considered, in view of the possibility of the ship being icebound in the coming winter. The aluminium launch is 18ft. in length, and constructed in several sections, each of which will float by itself, and when fitted up will carry from fifteen to twenty persons. It will be transported on sledges, and used by the land party for crossing open waters. The total weight of this launch is 150 lb.

---

# ARE THERE CERTAIN GENERAL PRINCIPLES UNDERLYING THE PROPER CONNECTION OF STEAM BOILERS AND ENGINES IN A POWER PLANT?*

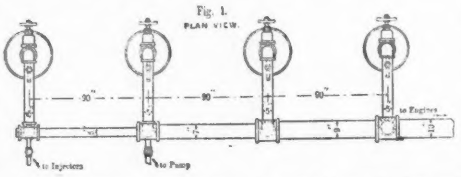
By Mr. THEODORE F. SCHEFFLER.

TOO much cannot be written about the design or construction of boiler and engine plants, either for electric light stations or for power plants, or, in fact, for any kind of a power station. Considerable space may be saved by leaving everything to the manufacturers, as well as economy secured in pipe connection. There certainly is a method for setting the engine connected to the boiler so that the best results may be obtained. For small plants, where there is but one boiler and engine, it is customary to set the engine about 12ft. to 14ft. from the boiler, and put an 8in. division wall between the boiler and engine-rooms, so as to keep all dust accumulating from ashes out of the engine-room. For the best results, engines should be set longitudinally with the boiler, so that direct pipe connections can be made. This is also, in the writer's opinion, the best method on account of the expansion of the steam pipe. In plants where there are three or four engines to be connected to a battery of boilers, and the engines are placed either directly in the rear, or in front of the boiler fire-room, there will be considerable waste of steam pipe, which will amount to quite an item on account of the steam pipe being large in diameter to accommodate the volume of steam from the boilers to the engine.

For the purpose of having some fixed basis to work from, the writer has taken for an ideal plant the following specifications of boilers and engines, and the necessary items to make a complete and modern steam plant.

*Boilers.*—Four 66in. by 16ft. horizontal tubular boilers, rated at 100-horse power each, and to be set in one battery with full arch fronts, and all necessary fittings, such as safety valve, steam gauge, and syphon, water-gauge, with stand-pipe fitted to the boiler, three gauge-cocks for each boiler, blow-off valve, two check-valves, two stop-valves for feed-pipe, main gate valve for steam outlet, rocking grates, grate bearers, stack-plate, rear arch bars, and rear ash door and frame. These fittings go with each boiler. One boiler cleaner for all four boilers.

Fig. 1.
PLAN VIEW.



*Engines.* — Four 13in. by 12in. non-condensing, high-speed automatic engines, to develope 90 indicated horse-power each; diameter of steam pipe, 4½in.; diameter of exhaust, 5in.; diameter of pulley, 54in.; face of pulleys, 12½in., with complete set of fixtures, such as throttle valve, large size sight-feed lubricator, full set of sight-feed oil cups, and automatic oiling devices for crank-pin and crosshead-pin, wrenches, crank shield, cylinder cock-drip connection for steam chest, foundation bolts, and one 4½in. steam separator for each engine; feed-water heater to be 42in. diameter with 100 2in. tubes 60in. long. Engines to set 9ft., centre to centre and longitudinally with boiler. Pump required for this plant, one 400-H.P. pump, or a pump capable of delivering 3000 gallons per hour, and all necessary pipe connections. Each boiler to have one injector of 100-H.P. capacity, or equivalent to forcing 800 gallons of water per hour into boiler, and all necessary fittings. In a plant of this size it is customary to use a feed-water reservoir tank. Where there is no city water pressure the tank is supplied with water by a pump, the tank being suspended above the boilers, so that the water will flow by gravity to the boiler feed pump, thereby keeping the pump valves flooded with water. One exhaust head should be connected to the main exhaust pipe after leaving the feed-water heater. Probably right here would be the proper place to say a few words in connection with the engine foundations. The depth of engine foundation should be at least 6ft., unless there is a good rock bottom found before reaching this depth, so that the engine anchor-bolts may be anchored directly into the rock; otherwise, if there is no such rock to anchor to, and the above depth has not been made, there will not be enough weight to the foundation to hold the engine down. The writer is well aware of the fact that there are engines on the market to-day where great care and attention has been given thoroughly to counterbalance the engine, so that the engine will run steadily and smoothly, set upon four pins, and will not jar or shake off the pins, the engine not being bolted to the foundation. The above is all right so far as it goes, but will not answer for large engines, and especially when the engine is very heavily loaded. The length of the foundation on the shaft end of the bed, measured from the centre of the shaft to the end of the foundation, should be equal to the length of the foundation measured from the cylinder end of the bed to the centre of the shaft. The correct proportion for this length of foundation is about seven and one-half times the stroke of the engine. In a great many cases this length of foundation on the shaft end of bed has been very much diminished. There is no better place to throw in brick on an engine foundation than on the shaft end; here is where the weight is required.

Fig. 3.

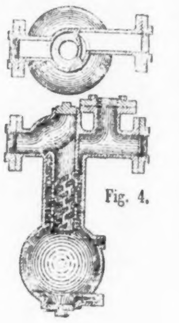

Fig. 4.

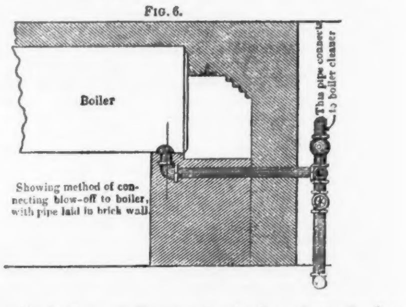
The above dimensions which have been given will make the end of the foundation equally divided on each side of the centre line of the shaft, making the centre of the shaft in the centre of the apex of the foundation. The width of the foundation at the bottom should be equal to eight strokes of the engine. In this case, the stroke of the engine is 12in. multiplied by 8in., which would be equal to 96in. The number of bricks which would be required for this foundation is 7500. Having found the proper dimensions of the engine foundations, it will be as well to give thought to the relative proportions of the boiler foundation and settings. The writer has found by experience that 3ft. deep will be sufficient for this size of boiler, below the floor-line. A good, hard sandstone will give good results when brick is not used, which some people prefer. The width of the foundation should be 6in. more on the floor-line than the boiler side walls, which in this case should be 24in. wide. There has been considerable argument about the best height from the floor-line to the fire door opening; 22in. to 24in. is a very satisfactory height, but 30in. is considered much more satisfactory and better adapted to the ordinary fireman. This height has been obtained for these boilers by raising the bottom of the fire fronts 6in. above the floor-line, as the height of opening is but 24in. in the casting. This method of raising the front has proved very satisfactory wherever it has been adopted. Another point to be considered on these boilers is the height from the top of the bridge wall to the under side of the boiler shell. The height in this case is 12in., and this gives an area between the top of the bridge wall and the bottom side of the boiler shell of 1550 square inches, which is equivalent

FIG. 6.



Showing method of connecting blow-off to boiler, with pipe laid in brick wall.

---

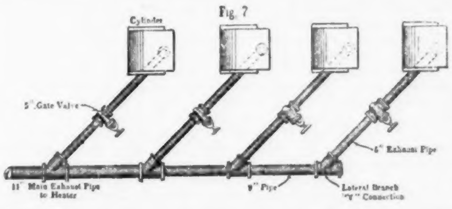
* Presented at the Montreal meeting—June, 1894—of the American Society of Mechanical Engineers.

to double the area of the boiler tubes. For the best results in combustion and efficiency, this height has proved to be very satisfactory. The bridge wall should be made horizontal on top. Some manufacturers recommend the top of the bridge wall to follow the curve of the under side of the boiler shell with the necessary area between the bridge wall and the boiler. Another good point for consideration is the distance from the top of the grates to the bottom of the boiler shell; in this particular case it is 26in. The height has proved to be very satisfactory. Of course there is a wide range of opinion on the height; some manufacturers prefer but 23in. to 28in., and some even prefer 30in. The writer has found this height to suit in almost every possible case. The height given is about the average, and will evaporate more water than if the height was 30in.

The boilers and engines having been set up on their foundations, the next point in view to consider is the main steam pipe and fittings. See Fig. 1 for illustration of the main steam pipe. We will first consider the correct diameter of the main steam pipe. As we have in this case four steam outlets from the four boilers, one from each of the boilers, and as the commercial diameter of each pipe is 5in., we shall require a main steam pipe with an area equal to four times the area of the 5in. pipe. The area of a 5in. pipe is 19·63 square inches. This multiplied by 4 gives 78·52, which is equivalent to a pipe 10in. in diameter. The pipe is constructed on the telescopic method, that is, the diameter of the pipe from the first boiler to the second boiler is 5in.; from second boiler to third boiler 7in.; from third boiler to fourth and last boiler 9in.; and from the last boiler to the engines the diameter is 10in. This pipe will carry all the steam which the four boilers can supply, and with a minimum resistance. Observing the end elevation—Fig. 2—the main steam pipe is at the extreme height. This arrangement allows of all condensed water flowing back towards the boilers. There should be a drip connection placed on the gate valve just above the valve seat, so that condensed water may be drained off. By this arrangement of drip-pipe, considerable water may be saved from getting into the engines. It will also prove to be economical and saving of steam from the boiler after the gate valve is opened; for if this accumulating water is not let out at the boiler after any one of them has been shut down, the steam will condense very rapidly. Of course this is only a small saving of steam.

The main steam pipe is located 36in. from the centre of the dome. This is done so that when the steam pipe expands or contracts, it will not make any strain on the screwed connection at the point marked A, but will naturally swing from the centre of the dome, the centre of the dome becoming the fulcrum of the main steam pipe. The steam pipe connections for the engines are made in the following manner, Fig. 3:—First, a short piece of 4½in. pipe is connected to the main steam pipe, and then to the steam separator. The steam taking a spiral course inside the separator, causes the water to be thrown by centrifugal force against the outer walls, while the dry steam goes through the small holes to the centre of the pipe. When it is not convenient to pipe up the separator as shown, steam may be taken into the separator at A. For sectional view of separator see Fig. 4. The separator should be located as close as possible to the engine, so that nothing but clean dry steam will be supplied to the engine. The main steam pipe is located 72in. from the 4½in. vertical steam pipe, which is connected directly to the engine throttle valve. This allows the 4½in. horizontal steam pipe connected to the separator to swing from the elbow B when expansion or contraction takes place. Fig. 3 also shows the exhaust pipe connected to the cylinder. For continuation of exhaust pipe connected to feed-water heater, see Fig. 5.

Fig. 7

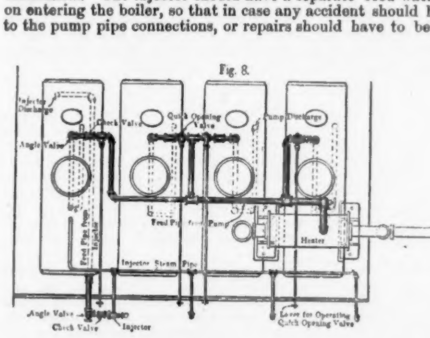


Cylinder
5" Gate Valve
6" Exhaust Pipe
11" Main Exhaust Pipe to Heater
9" Pipe
Lateral Branch "Y" Connection

The best and usually the most convenient place to locate a feed-water heater is on top of the boiler side walls, placed at right angles to the boiler and set horizontally, the heater being supported at each end by a cast iron leg or bracket, and each bracket anchored into the boiler side walls by anchor bolts.

This method of locating the heater has been, as described above, placed on several large boiler settings which the writer has designed. Any person who is in any way familiar with boiler settings knows how hot it is over the top of boilers, and can readily see the advantage of locating the feed-water heater above the boilers. From 5 deg. to 10 deg. of additional heat will thus be obtained for the feed-water over that supplied, if the heater is set up, as is common practice. To set the heater on top of the boiler will cost a little more, but it will soon pay for itself by being economical. The injector should have a separate feed-water pipe on entering the boiler, so that in case any accident should happen to the pump pipe connections, or repairs should have to be made on the pump or to any of the connections, there will be no loss of time by having to draw off the steam from any of the boilers, in order to make the necessary repairs. If necessary, by closing the main feed-water pipe valve connected to the pump line of pipe, after the water is forced through the heater, and by closing the feed pipe valve over each boiler, the whole line of pump pipe connections may be disconnected, and the boilers fed with the injectors. A check valve should be placed over each boiler for the feed pipe, and also between the pump and heater. This will keep all pressure away from the pump and will be beneficial in case anything should happen to the boiler checks. The blow-off from the heater is connected to the main blow-off pipe, as well as the overflow from the injectors, and the discharge may be connected to any convenient point which will be the nearest at hand, or may be carried to the sewer. To operate the blow-off on the boiler or heater, the globe valve on the injector pipe should be closed. The injectors are supplied with water from the water tanks overhead; this will give a constant supply of water under a head of water at the injector.

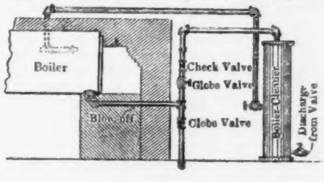
Fig. 8.



The main steam supply is connected to the main line of steam pipe leading to the engines. The idea of doing this is in case anything should happen, so that any one or two of the boilers should be off duty, the supply of steam would be constant, in taking steam from the main line of steam pipe. A good way to connect the blow-off pipe to the bottom of the boiler shell and keep the pipe intact from burning out, is to build a small wall of fire-brick, about 9in. thick, and lay the pipe in the centre of the brick. This wall will not diminish the area of the combustion chamber enough to destroy any of the draught. For illustration of this pipe connected to boiler, see Fig. 6. The exhaust pipes leading from the engines to the main exhaust pipe should be constructed so that there would be a minimum amount of back-pressure. To do this satisfactorily and with the best results, a lateral branch Y connection should be made where the pipe meets the main exhaust pipe. For an illustration of this design, see Fig. 7. A valve should be placed on the pipe leading to the main exhaust pipe, so that in case any one of the engines is stopped for repairs, the exhaust steam from the other engines would not back up into the steam chest, in case the valve on the engine was disconnected from the engine. The Y connection also does away with the short and sharp angle connection and makes a freer passage for the steam.

Referring to Fig. 8, we have a plan view of the pump feed-pipe connections with fittings, also the injector connected to the boiler. It will be observed that the injector pipe runs nearly the whole length of the boiler and toward the rear before discharging the water directly into the boiler. The advantage of this is apparent. The feed-water becomes well heated before discharging into the boiler, and its chilling action on the shell is greatly lessened. There has been considerable discussion about where the feed-water should enter the boiler, and the writer believes that this method is freer from objection than any other which could be selected. The pump feed enters the boiler at one-quarter the whole length of boiler, at the rear, and the pipe is kept as close as possible to the boiler shell, so that there will be room enough for a man between the pipe and the top of the tubes. The pipe then continues ahead about 8ft. and then turns towards the boiler shell on the side, and then turns and comes back where it started from and discharges downwards. Some persons may say there are too many turns employed in this method, but the feed-pipe is made much larger after it enters the boiler to reduce the resistance caused by friction to a minimum. Fig. 8 also shows a plan of the feed-water heater.

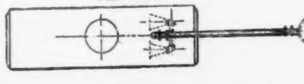
FIG. 9.
Showing arrangement for connecting Boiler Cleaner to Boiler



Figs. 9 and 10 illustrate the method for connecting the boiler cleaner to the four boilers. The reservoir for receiving all of the sediment collected from the boilers is located centrally between the four boilers, in the rear. The action of the boiler cleaner is here described. As the water boils and circulates towards the top and rear of the boiler, the scoops gather all sediment which rises to the surface of the water, and is then discharged by the boiler pressure into the reservoir. The water and steam may be let out of the boiler, independent of the boiler cleaner when it is necessary, by closing the valve connected to the boiler cleaner and opening the valve connected to the blow-off pipe proper. There is a globe valve attached to the bottom of the reservoir, where the sediment which has collected may be let out. This sediment should be let out every other day.

The writer desires to say, in conclusion, that about twenty plants have been connected up as described in this article, although they have not all had boiler cleaners, nor has the injector been connected separately to the boiler, and the engines and boilers were arranged somewhat differently in the setting; but all are giving good satisfaction, and the piping in general was arranged as described here. Further, in regard to piping in general, in case of any accident to any part of the plant, the part which is crippled may be shut off without shutting down the whole plant. The steam will reach the engine with but little drop in pressure, as all pipes are covered with an asbestos air-space covering. Much more can be written on this subject and on this same plant; and the writer desires to say that some time in the future it would be interesting to give an approximate estimate as to the cost of the entire plant. The main object of this article is to create a fruitful discussion.

FIG. 10.
Plan of Boiler Cleaner



LOWNESS OF ITALIAN WAGES.—The British Vice-Consul at Ancona, in a recent report on the trade of that district, gives an additional instance of the very low wages paid in Italian industrial establishments. At the metallurgical works of Messrs. D. Cattro and Co., a firm giving constant employment to over 200 hands, although wages have increased by about 10 per cent. in the last three years, the average rates paid per day of 10½ hours are—to boilermakers, 3s. 2d.; iron founders, 2s. 11d.; riveters, 2s. 11d.; turners, 3s. 2d. The works are being enlarged, and accommodation will be provided for building steamships of any size or tonnage. Coal, coke, pig iron, and all materials for boilermaking are imported from Great Britain.

SHIPPING STATISTICS.—It appears from Lloyd's Register that 2401 iron steamers of a tonnage of 2,769,555 tons and 2063 steel steamers of a tonnage of 4,347,177 tons are classed in the United Kingdom out of a total of 3132 iron steamers of 3,738,340 tons and 2716 steel steamers of 5,505,304 tons. Of sailing vessels 1109 iron ships of 1,416,107 tons and 464 steel ships of 857,591 tons are classed in the United Kingdom; and of wooden ships, including composite vessels, 659 of a tonnage of 119,486 tons are also classed. The total number of vessels classed in the book for the present year is 30,721 with a total tonnage of 24,569,496 tons. This compared with last year's book, which had 32,010 vessels of a total tonnage of 24,258,375 tons, shows a decrease in number of vessels, but an increase in the total tonnage.

COST OF FIRST-CLASS CRUISERS.—At a conference of members of Parliament held at the Westminster Palace Hotel, to consider the excessive cost of the first-class cruisers, the proceedings were commenced by a statement from Sir E. J. Reed, who, while deprecating any general interference between the Admiralty and their contractors, represented that in the case of the Thames Ironworks Company, Earle's Company of Hull, and Napier's of Glasgow, all of whom had been engaged upon the construction of first-class cruisers for the Admiralty, there were very special circumstances which appeared to him to justify the interference of Parliament. We read in the *Times* that numerous questions were asked, both by Sir E. J. Reed and of the representatives of the contracting firms in question. It was felt that the arbitration clauses of the respective contracts had not yet been sufficiently acted upon, and it was the unanimous opinion of the members present that before any further parliamentary action was taken those clauses should be formally enforced.

## AMERICAN ENGINEERING NEWS.

(*From our own Correspondent.*)

*A heavy locomotive.*—The heaviest locomotive of the mogul type—six driving wheels and a two-wheel leading truck or bogie—in the world has been put in use for coal service on the Delaware, Susquehanna, and Schuylkill Railway. It weighs 76 tons in working order, has a boiler 6ft. diameter, and driving wheels 5ft. 2in. diameter. The fire-box is designed for lump anthracite coal, and has annealed cast steel plates $\frac{5}{16}$in. thick, with ⅜in. crown sheet, and ½in. tube plate. It has the ordinary link motion, with Richardson balanced valves. The fire-box crown sheet has radial stays 1in. diameter. An extension smoke-box is used, with a short cylindrical smokestack or funnel. The crossheads are of cast steel. Compressed air is used to ring the bell and to operate the Leach sanding apparatus. The coupling and connecting-rods are of iron, with forged oil cups. The boiler is of ⅝in. steel plates, the longitudinal seams being butt jointed, with double riveting and double cover strips. The tender is carried on six 42in. wheels, like the tender of one of the Pennsylvania Railway express engines. The cylinders are 22in. by 26in., with two-bar guides. The cab is of steel plate.

*Gasoline tramway engine.*—One of the latest of the many engines invented for use on street railways or tramways is the Regan engine, tried recently in San Francisco. The motive power is an internal combustion engine, using gasoline or benzine mixed with air as the explosive mixture, the charge in the cylinder being fired by an electric spark. The engine is vertical, inverted, and runs continuously, driving a shaft lengthwise of the car, which carries a pinion. This pinion gears with a spur wheel on a shaft under the car, which carries at each end a bevel pinion gearing with a bevel wheel on each of the two axles. The power is regulated by the charge, which varies automatically with the load on the car; and starting or stopping is effected by throwing the engine in or out of gear with the lower driving shaft. The experimental car is similar to a cable railway open-grip car, being carried on four wheels and having two lengthwise side seats back-to-back, the working levers being operated by a man standing in the space between the backs of the seats. The car is 13ft. long, seating twenty passengers—ten each side—and is carried on four wheels 28in. diameter, with a wheel base of 6ft.; its weight is four tons. The engine is of 15-horse power, constructed to run at 200 to 350 revolutions per minute, and consumes one-third to one-quarter of a gallon of oil per car mile with speeds of six to eight miles per hour, though it can be speeded up to twelve or fifteen miles. The oil costs 13 cents per gallon in San Francisco, and 5 cents per gallon in New York.

*Railway operating statistics.*—The discussion on English and American railway rates is very largely based on average figures, which are in many ways unsatisfactory, in that they do not represent actual but imaginary conditions, which have little practical bearing. On the other hand, comparisons of specific rates are also unsatisfactory, since rates are not based upon any system—mathematical or otherwise—but depend largely upon circumstances and conditions. The following figures, however, giving the operating details of the Chicago, St. Paul, Minneapolis, and Omaha Railway for the year 1893 are interesting examples of specific results for that one road, which has a length of 1495 miles:—

| | |
|---|---|
| Gross earnings per mile | 5,607·31 dols. |
| Operating expenses and taxes per mile | 3,934·06 dols. |
| Net earnings per mile | 1,673·25 dols. |
| Passengers carried | 1,738,656 number |
| Passengers carried one mile | 86,021,354 number |
| Average rate per passenger per mile | 2·409 cents |
| Freight carried | 3,198,878 tons |
| Freight carried one mile | 524,073,368 tons |
| Average rate per ton per mile | 1·124 cents |
| Engine mileage | 7,477,431 miles |
| Cost of engine and tender repairs per mile run | 3·76 cents |
| Cost of engineman, firemen, and wipers per mile run | 7·42 cents |
| Cost of oil, waste, and tallow per mile run | 0·28 cents |
| Cost of fuel per mile run | 11 10 cents |
| Total cost per mile run by engines | 22·56 cents |
| Mileage per ton of coal | 26·07 miles |
| Mileage per pint of oil | 15·45 miles |
| Mileage per pound of waste | 137·83 miles |
| Average earnings per mile run by passenger trains | 1·27 dols. |
| Average earnings per mile run by freight trains | 1·66 dols. |
| Average earnings per mile run by all trains | 1·53 dols. |
| Average expenses per mile run by all trains | 1·07 dols. |
| Net earnings per mile run by all trains | 0·46 dols. |
| Average cost per ton of coal consumed | 2·87 dols. |

| Average number of passenger trains per day | 80 |
| Average number of cars per passenger train | 5 |
| Average haul per passenger | 50 miles |
| Number of freight trains run | 54,416 |
| Average number of freight trains per day | 174 |
| Average receipts per passenger | 1·19 dols. |

*Metallic sleepers for railways.*—A very complete report on the use of metallic sleepers for railways, giving statistics and details of experience in all parts of the world, was prepared about five years ago by Mr. E. E. Russell Tratman, C.E., of New York, for the Forestry Division of the United States Government, and was issued by that department in 1890. Two editions of the report have already been exhausted, and Mr. Tratman is now preparing a supplementary report to accompany a third edition, which is to be issued this year. This new report will bring the statistics and records of experience as nearly as possible up to date, but will also take up the subjects of the use of preservative processes for wooden sleepers, and the use of metal base plates to protect wooden sleepers from wear by flange rails. These two latter subjects are of much more immediate importance in the United States than the former, but while the use of steel base plates has reached a very remarkable development, preservative processes are still comparatively little used. The zinc process is that most generally employed, though creosoting and vulcanising are also employed. Flange rails are used exclusively in the United States, and where laid direct on unpreserved wood, the slight motion of the rail wears and abrades the wood, causing local rot. Some preservative processes harden the wood, but the best prevention against this class of wear is found in the use of the metal base plates, and a permanent way built of heavy flange rails resting on base plates, and well secured to the sleepers by screws or other fastenings, is as strong and secure as that built with bull-head rails and chairs, as proved under the ponderous locomotives and cars and the fast and heavy traffic of the principal lines. In the original report of 1890 actual statistics were given, showing that no less than 25,000 miles of railway, or 13 per cent. of the railway mileage of the world at the end of 1889, were then laid with metal sleepers—including transverse sleepers, cast iron bowls and plates, and metal longitudinals. England had comparatively little, the aggregate being but seventy miles, of which Mr. Webb's steel sleepers of the London and North-Western Railway had fifty-six; the North-Eastern, five miles, and the Midland Railway five miles. This country had, however, a large business in the manufacture of rolled steel and cast iron sleepers for the Colonies and South America, and during the years 1874 to 1889 nearly 4,000,000 sleepers were sent out to the Indian State Railways. Of the Australian colonies only Queensland has used metal to any extent, as there is a large supply of hard and durable timber. In America metal has been very little used, but since the above report was issued, one road has laid 20,000 steel sleepers with 100-pound rails, and expects to obtain a decided saving in expenses for maintenance. This road has had about half a mile of steel sleepers in use for over four years, and they have given great satisfaction. The new report will probably show a decided increase in the mileage laid with metal sleepers, more especially in India and Germany, and on some of the new pioneer railways of Africa.

*Electric traction for canals.*—The authorities of the New York State canals have taken an important step in granting the Cataract General Electric Company a fifty-year permit to put in some kind of an electric plant along the lines of the State canals by which boats can be operated with electricity. The company shall not charge for use of such power by the canal boatmen at a rate exceeding 20 dols. per electrical horse-power for each season of navigation, but that is the maximum charge that can be made, and the rate will undoubtedly be much lower. Even at 20 dols. a horse-power it is claimed that an owner would be saved 50 per cent. a season on the operation of his boat in comparison with the present cost of canal boat propulsion. The operations of the company are not in any way to interfere with boats navigating the canal by steam or horse-power. The company made several experiments on the canals last autumn, as previously noted, and the matter will now be pushed forward to a successful solution of the problem. The electrical power will be obtained from the great water power plant at Niagara Falls, and transmitted by wires erected along the line of the Erie Canal. The permit authorises the company to enter upon all canal lands of the State for the purpose of constructing either on or over or under either canal bank a system for propelling canal boats by electricity, without interfering with the present method of operation. Central power houses may be erected. The rates for towage shall be subject to modification and review by the State Superintendent of Public Works, but such rate shall not exceed 20 dols. per electrical horse-power for any season of navigation. An important provision is that the company may, so long as the wants of the canal are supplied, employ its electric plant along the line of the canal in furnishing electric light, heat and power for distribution to any point or points beyond the line of the canal, and thus may furnish electricity for lighting and power purposes in all of the cities and villages along the canal. The company is to furnish the State, free of charge, sufficient power to operate motors, to open all gateways leading to and from locks, and also electric lights sufficient to properly illuminate such locks at night. The company must have its plant for operating boats by electricity in operation on the Erie Canal between Buffalo and Albany within three years from date, or else the privileges accorded by the permit shall be forfeited. In case the company shall construct along the canals an electrical plant for use, known as the trolley or overhead wire system, it shall be the privilege of the State to condemn and purchase such property at a price equal to the actual original cost to the original constructor, with the 10 per cent. added thereto. All work done by the company shall be subject to the approval of the Superintendent of Public Works. All damages growing out of the use of electricity on the canals shall be borne by the company, and the State shall in no way be put to any expense on account of the granting or operation of the permit. Another electric traction project is that of the Erie Electric Towing and Power Co., which will construct and put in operation as soon as possible half a dozen tug boats, operated by electricity, either on the storage or trolley system, with a view of showing the adaptability of electricity to canal navigation. These tugboats will also tow for a moderate consideration any horse boats, the captains of which desire to avail themselves of such method of navigation.

*Test of rapid-fire guns.*—An interesting test of rapid-fire guns was made recently at the Government Proving Grounds, at Sandy Hook, the guns being of five different makes, namely, (1) the Driggs-Schroeder; (2) the Hotchkiss; (3) the Sponsel; (4) the Maxim-Nordenfeldt; and (5) the Skoda. All of these were 6-pounders, with the exception of the Skoda gun, which was a 3-pounder. The trial showed that the Driggs-Schroeder gun was easier to handle than any of the others, and had the advantage of rapidity of fire. Previously the pieces had been fired to test the action of the mechanism, their accuracy at various ranges, the velocity of the projectile, and the time required to fire 100 rounds. The purpose of this test was to ascertain how many rounds could be fired from each gun in five seconds, and also in three minutes. After the three-minute round, the representative of each gun was required to fire one shot, remove the mechanism, change and replace it and fire another shot, the interval between the shots being the time recorded for the change. In the final test of the number of rounds fired in five seconds, the Driggs-Schroeder gun again distanced its competitors by thrice discharging three shots with a fourth round in the chamber on the last round. The other guns fell slightly behind this record. Many of the Driggs-Schroeder and Hotchkiss guns are already in use in the navy. In the tests the Driggs-Schroeder gun was served by three men; the other guns were each served by four men. The tests resulted as follows:—

*Driggs-Schroeder Gun.*

| | |
|---|---|
| Total number of rounds fired in three minutes .. .. .. | 83 |
| Number fired in the first minute .. .. .. .. .. .. | 34 |
| Time in changing mechanism .. .. .. .. | 2 min. 4⅜ sec. |

*Hotchkiss Gun.*

| | |
|---|---|
| Total number of rounds fired in three minutes.. .. .. | 83 |
| Number fired in the first minute .. .. .. .. .. .. | 28 |
| Time in changing mechanism .. .. .. .. | 1 min. 37⅞ sec. |

*Sponsel Gun.*

| | |
|---|---|
| Total number of rounds fired in three minutes .. .. .. | 73 |
| Number fired in the first minute .. .. .. .. .. .. | 24 |

Mechanism not changed because representative of gun was not present.

*Maxim-Nordenfeldt Gun.*

| | |
|---|---|
| Total number of rounds fired in three minutes .. .. .. | 65 |
| Number fired in the first minute .. .. .. .. .. .. | 20 |
| Time in changing mechanism .. .. .. .. | 3 min. 33⅜ sec. |

*Skoda Gun (for exhibition only).*

| | |
|---|---|
| Total number of rounds fired in three minutes .. .. .. | 55 |
| Number fired in first minute .. .. .. .. .. .. .. | 24 |
| Time in changing mechanism .. .. .. .. .. .. | 33⅜ sec. |

*Compound locomotive.*—The Golsdorf system of compound locomotives, as used on the Austrian State Railways, has been taken up by an American company. By using the Walschaerts valve gear, with which a cut-off of 90 per cent. can be obtained, the counter-effect of the steam on the high-pressure piston at starting can be neglected, and an intercepting valve dispensed with. Small steam ports, uncovered, with the valve at full travel as in starting, admit steam to the low-pressure cylinder if the high-pressure cylinder's steam port is closed by the valve.

## LAUNCHES AND TRIAL TRIPS.

ON Thursday afternoon, the 5th inst., Messrs. Craig, Taylor, and Co., launched from their Thornaby shipbuilding yard, Thornaby-on-Tees, a steel screw steamer of the following dimensions:—227ft. by 33ft. by 16ft. ½in. She is built to the highest class in Lloyd's, and is of the long raised quarter-deck type, with bridge and top-gallant forecastle, and is specially adapted for the coal trade. She will be fitted with triple-expansion engines of the following size, viz., 17½in., 29in., 47in., and 33in. stroke, by Mr. John Dickinson of Sunderland, and will also have three steam winches, steam steering gear, steam windlass, and all the latest improvements. She has double-bottom all fore-and-aft, on the cellular principle for water ballast, and is rigged as a two-masted schooner. She has been built to the order of Mr. John S. Barwick, of Sunderland, for whom Messrs. Craig, Taylor, and Co., have built a number of vessels.

On Tuesday, the 3rd inst., Messrs. Wigham, Richardson, and Co., launched from their Neptune Shipyard, Newcastle-on-Tyne, a finely modelled steel screw steamer, which they are building to the order of the Bulgarian Trading Steam Navigation Company, of Varna, Bulgaria. The steamer has a clipper bow, and will be rigged as a two-masted fore-and-aft schooner; she is 240ft. in length, and 33½ft. beam. She will also have very well-finished accommodation for first and second-class passengers. The engines and boilers are also being constructed by Messrs. Wigham, Richardson, and Co., and are expected to drive the vessel at a high speed. As the vessel left the ways she was named the Bulgaria by Miss Elsie Tweedy, daughter of Mr. John Tweedy, one of the members of the firm of Wigham, Richardson, and Co.

On Saturday, 7th inst., the s.s. Metal, built by Messrs. Cumming and Ellis, Inverkeilting, for Messrs. Wm. Jacks and Co., Glasgow and Grangemouth, ran her trial trip on the Firth of Forth. After several runs the vessel was found to be steaming at the rate of 11 knots, which exceeded the anticipations of the builders and owners. The vessel is designed to carry a deadweight of 820 tons, her dimensions being 180ft. by 27ft. 6in. by 13ft. 6in., and will immediately be put on the trade she was built for, viz., carrying pig iron between Middlesbrough and Grangemouth. All modern appliances for the rapid loading and discharging of cargo, as well as for working the vessel in dock and at sea, have been supplied by the builders. To enable the vessel to make good passages at sea without cargo, she carries water ballast in her fore and after holds and after peak, with an extra large donkey pump fitted so that the tanks may be emptied rapidly. The engines, which are triple-expansion, having cylinders 15in., 25in., and 40in., by 27in. stroke, are supplied with steam by a large multitubular boiler working at 160 lb. pressure; a large donkey boiler is also fitted for supplying steam to the winches. The machinery has been supplied by Messrs. Muir and Houston, Glasgow.

On Wednesday, 4th July, Messrs. Furness, Withy, and Co., launched from their shipbuilding works at Hartlepool a large steel screw steamer, built to the order of the Parks Steamship Company, of London. The vessel is a very substantial type of a modern cargo boat, measuring over 300ft. in length, and built throughout of Siemens-Martin steel, with a large measurement and deadweight capacity, and built to the highest class at Lloyd's. Every care has been taken in designing this ship to construct her as substantial as possible for the heavy deadweight trade. She is built on the web frame system, with cellular double bottom for water ballast, all fore-and-aft, and subdivided at intervals; the after peak being also available as a tank. To further ensure the safety of the vessel, the middle of the main and fore holds are divided by iron water-tight bulkheads, these bulkheads being efficiently stiffened by an iron longitudinal division. It is anticipated that by the extra amount of subdivision in water ballast tanks and holds, with the efficient way the pumping gear is arranged, the vessel will be practically unsinkable by collision or stranding. To get as much strength as possible, the greater portion of the shell plating is in 24ft. lengths, this plating being efficiently backed up by strong sectional framing, carrying the strength to the top of the vessel all fore-and-aft; the topside plating being extra thick to withstand the heavy Atlantic trade, also the bottom plating is thicker in way of all ballast tanks, to allow for the vessel lying aground whilst taking in cargo. To allow for corrosion, the whole of the weather decks, tank tops, floor plates, &c., are of extra thickness, there being practically no thin steel in the ship. She has extra large-sized hatchways, which will take the bulkiest description of cargo, and would be especially suitable for carrying machinery, large guns, torpedo boats, &c. A new design of bilge intercostal keelson is fitted in the holds—Sivewright's patent. By this new arrangement very much of the dunnage and damage to bag cargo is avoided, there being no pockets or receptacles for loose grain, coals, dirt, &c., consequently these keelsons can be more rapidly cleaned down when discharging cargo. The accommodation for the officers is on deck in a large deck-house at the fore part of engine-room, and that of the engineers under the after end of bridge; this ensures a good ventilation in hot climates, and in the heaviest weather all the officers are close to their work. The auxiliary machinery for working and discharging cargo is of the most efficient description—large winches to hatches, patent steam steering gear amidships, with hand-gear aft steam windlass, and the anchors being of the stockless pattern, they can be stowed into hawse pipes, and the whole operation of catting and lifting the anchors can be done by one man in a few minutes. The vessel will be rigged as a pole-masted schooner, and to make her available for bridge and canal work, the topmasts are telescopic. The engines and boilers have been constructed by the well-known firm of Messrs. T. Richardson and Sons, Hartlepool, and are of massive design, with every provision for economical working. The ship and engines have been constructed under the supervision of Captain J. R. James. On leaving the ways the vessel was named Windsor Park, by Mrs. Lloyd Owen, of London.

## THE IRON, COAL, AND GENERAL TRADES OF BIRMINGHAM, WOLVERHAMPTON, AND OTHER DISTRICTS.

(*From our own Correspondent.*)

THE quarterly meetings of the iron trade were held here to-day, Thursday, and in Wolverhampton yesterday. There was to-day a good attendance from, as usual, various parts of the kingdom, and a fair amount of business was transacted. The situation was declared to be improved by the more settled prospects of the coal trade, by reason of which iron and steel masters will probably be able to gauge their expenses for fuel for a couple of years ahead. Then another feature which inspired cheerfulness was the passing of the American Tariff Bill through the Senate. Prices just recently quoted were therefore maintained in all departments, though these compared with a quarter ago were generally found to be somewhat lower than at that time. Engineering sections of steel were freely inquired for, and a good deal was on offer, not only from local, but from Welsh and North of England firms. Generally speaking, steel sold well at £5 10s. to £5 12s. 6d., and £5 15s. for bridge and constructive engineering plates, £5 5s. for angles and girders, £6 10s. for boiler plates, £5 2s. 6d. to £5 5s. for plating bars, and £5 15s. for wire rods. Special makes were re-quoted at the prices given last week.

In the manufactured iron trade, marked bars were re-declared at £7 10s., and this being so, other descriptions of marked iron made by the "list" firms were also unaltered on the quarter, rivet iron of this description being £8 10s. to £9; boiler-plates £8 10s. up to £11 10s.; and hoops and angles £8. Indeed, marked iron has not been altered for a year and a-half; but during the same period unmarked iron has greatly declined. Thus common bars, which are now £5 5s. to £5 10s., and merchant bars, which are now £6 5s. to £6 10s., are both lower than eighteen months ago by 5s. A drop of 5s. or 7s. 6d. appears in hoops and gas tube strip during the same period, the former being this afternoon £6 5s. as selling rate, though the Association figure of £6 10s. is nominally maintained. Gas tube strip is £5 7s. 6d. to £5 10s. and £5 15s.

Black sheets for galvanising have also fallen during that time by from 7s. 6d. to 10s. They were quoted to-day £6 7s. 6d. to £6 10s. for doubles, and in some cases £6 5s., with lattens £7 2s. 6d. to £7 5s. Indeed, sheet values are at a very low ebb. Galvanised corrugated sheets are £9 15s. to £9 17s. 6d. f.o.b. Liverpool, with restricted Australian and South American demand. Some good sales were made in Midland pig iron at about 42s. to 42s. 6d. for Lincolns, 41s. to 42s. for Derbyshire, and 39s. to 40s. for Northampton. Staffordshire sorts were quoted 38s. 6d. to 40s. for cinder sorts, up to 95s. for all mine cold blast sorts. Taking the pig iron market as a whole, it was sustained by the coal position, though if the 10 per cent. miners' wages question comes into force this may slightly weaken the market. At present, however, vendors are firm.

A question of much interest to engineers engaged in constructive work has just been raised here in connection with the question of steel-making in Staffordshire. It is pointed out that at the present time buildings are being erected in Birmingham supplied with steel girders, beams, and other engineering steel sections, rolled at Middlesbrough, and imported into this district. The inquiry is raised whether this class of engineering work could not be turned out in this district, seeing especially that local-made girders would have an advantage in the matter of carriage of, say, 10s. or 15s. per ton. Alike solid-rolled and built-up girders are being imported from the North of England, and it is regarded that such manufactures might be equally well made here. For myself I see no sufficient reason why this suggestion should not be adopted, though of course it would mean great expense in the laying down of special machinery; and sufficient credit is not given to English firms for having begun to take this trade from the Belgian ironmasters, which, it will be remembered, was previously wholly in their hands.

Birmingham manufacturers are anticipating with lively satisfaction a visit—which it is this week rumoured is in contemplation—by the Czarovitch, whilst in this country, to Birmingham, Manchester, and some of the other industrial centres, with a view to making a private inspection of some of the leading manufactories. It is thought to be eminently desirable that the Czarovitch should obtain an impressive idea of the industrial energy and enterprise of our large manufacturing centres whilst in this country; hence the intended inspections.

The site of the new works which have been commenced in the Elan Valley, Mid-Wales, to supply Birmingham with water were visited this week by members of the City Council. At present the work is only in the earliest stages of excavation. The scheme has already been described in these columns. The party were conducted over the site by Mr. Mansergh, the engineer, and the spots were pointed out where it is intended to construct dams and reservoirs for providing Birmingham with 27 million gallons of water per day in the driest season and a similar large quantity of compensation water.

## NOTES FROM LANCASHIRE.

(*From our own Correspondent.*)

*Manchester.*—The probability of some permanent settlement of the wages question in the coal trade is necessarily just now the matter which is most largely occupying attention, and there is little doubt that if some such arrangement as that which is embodied in the suggested terms of settlement agreed to by the coal-owners' and miners' representatives at the informal meeting held in London last Friday can be carried into effect, it would be an advantage not only to the coal trade, but also to the large coal-using industries. In some quarters there is a disposition to regard the proposed settlement as too much of a concession to the impracticable demands of the Miners' Federation, but I have reason to know that it is the outcome of much patient conciliatory effort on the part of Mr. T. R. Ellis, the secretary of the Coalowners' Federation, who has been met in a very reciprocal spirit by Mr. T. Ashton, the secretary of the Miners' Federation, both of these gentlemen being exceedingly anxious that some amicable and at the same time satisfactory arrangement should be come to which should prevent further disastrous struggles in the coal trade. Looked at superficially, the proposed terms with regard to the regulation of wages during the ensuing two years might seem to be a concession of the principle of a minimum wage; practically, however, it is simply an agreement to fix both a maximum and a minimum wage over a definite limited period, at the end of which the whole wages question is open for consideration or revision, a very different thing from the demand of the Miners' Federation for a permanently fixed minimum rate of wages, to which the Federated Coalowners and their representatives on the Conciliation Board are as strongly opposed as ever.

The prospect that some definite and binding agreement may be come to on the wages question in the coal trade by the meeting of the Conciliation Board next Thursday, coupled with a present reduction of 10 per cent., has necessarily had a tendency for the time being to check operations in the iron and coal markets, owing to anticipations of the possibility of some easier tone being given to prices, and that also it may bring about a settlement of the miners' strike in Scotland, as any further action on the part of the Miners' Federation with regard to this dispute will necessarily be largely governed by the agreement which may be come to by the Coal Trade Conciliation Board on Thursday.

There was not more than a moderate attendance on the Manchester Iron Exchange on Tuesday, and only a very slow business was reported generally, both merchants and consumers showing less eagerless to buy owing to the more settled outlook in the coal trade. In pig iron there is very little doing, and Lancashire makers remain practically out of the market. Nominally, they still quote on the basis of about 39s. 6d. to 40s. for forge, to 42s. for foundry, less 2½, at the works, but except under very special conditions, they are unable to book orders of any moment at these figures in competition with the much cheaper brands of Lincolnshire. Quotations for Lincolnshire iron remain at about 38s. 6d. for forge, to 39s. 6d. for foundry, net cash, delivered Manchester, but even these low figures are scarcely being realised in all cases. Derbyshire foundry brands are offered at about 44s. 6d., and 45s. up to 46s., according to quality, net cash, delivered Manchester, whilst neither in Lincolnshire nor Derbyshire is there anything of moment doing. Outside brands offering here are still quoted at late rates, but there is rather a weaker tone, and some irregularity in prices in the open market, with little or nothing doing to afford any real test of what sellers are disposed to take. Foundry brands of Middlesbrough nominally average about 43s. 10d. to 44s. 4d. net cash, delivered Manchester, with Scotch iron quoted about 44s. 6d. for Govan, and 46s. to 46s. 6d. for Eglinton, and 50s. to 50s. 6d. for Gartsherrie, net prompt cash, delivered at the Lancashire ports.

Finished iron makers here and there report that if anything there is rather more business stirring, but, taking trade all through, there is no real improvement, forges for the most part being still only partially employed, and prices are weak. Lancashire bars average £5 7s. 6d. to £5 10s.; Staffordshire, £5 10s. to £5 12s. 6d.; Lancashire sheets, £6 17s. 6d. to £7 2s. 6d.; and Staffordshire about £7 5s., with official list rates for Lancashire hoops remaining at £5 17s. 6d. for random, and £6 2s. 6d. for special cut lengths, delivered Manchester or Liverpool.

In the steel trade only a very limited business comes forward, with prices about as last quoted, ordinary foundry hematites averaging about 52s. 6d., less 2½; ordinary basic billets, £4 net cash, with steel boiler plates quoted at about £6 10s. per ton delivered in the Manchester district.

A very slow business characterises the metal market, with no further change in list rates for manufactured goods.

The position as regards the engineering industries remain very much as reported recently, new work coming forward very indifferently, and establishments only in exceptional cases more than very moderately off for orders. There are a few more inquiries just now stirring in the locomotive trade, but the improvement recently reported amongst boilermakers is scarcely being maintained, whilst it is only on special work that machine tool makers are at all busy, and stationary engine builders are not more than fairly off for work generally.

The reports received by the trades union organisations connected with the engineering industries are also generally to the effect that the condition of trade remains without any appreciable improvement. Stationary engine builders, in some cases, are slightly better off, but marine and shipbuilding centres continue in a very depressed condition; machinists in a great many cases are fairly off for work, but tool makers are only moderately employed. As regards employment, there is no specially noticeable improvement in this direction, and the position with regard to out-of-work members remains very much the same as it has been for the last two or three months.

A very quiet tone continues throughout the coal trade as regards the inland demand for all descriptions of fuel, and the probability that some arrangement may be come to for a reduction of 10 per cent. in wages is rather inducing buyers to hold back in the expectation that possibly this may have a weakening effect upon prices. Any reduction in miners' wages has, however, been already more than discounted by the very considerable fall in prices that has taken place since the commencement of the year, and at the various district meetings, and also at the council meeting of the Lancashire Coal Sales Association held during the week, it was decided that no change whatever should be made upon the present official list rates. For all descriptions of round coal the demand continues extremely poor, either as regards house-fire consumption or requirements for iron-making, steam and general manufacturing purposes, and except where collieries are being kept fairly busy on shipping orders, they are scarcely able to work four days wer week, with stocks accumulating even with this restricted output. Qroted prices, however, remain at about 11s. to 11s. 6d. for best Wigan Arley; 10s. to 10s. 6d. for Pemberton four-feet, and seconds Arley, 8s. to 8s. 6d. for common house-fire coals, and 7s. to 7s. 6d. for steam and forge coals, at the pit mouth. Engine classes of fuel are plentiful in the market, and for these prices are rather easier, common qualities of slack being readily obtainable at 4s. to 4s. 6d., medium sorts 5s. to 5s. 6d., with special descriptions of slack quoted at about 5s. 9d. up to 6s. 3d. per ton, at the pit mouth.

With regard to the proposed settlement of the wages question in the coal trade, on the basis set forth in the suggested terms agreed to by the coalowners and miners' representatives in London last week, there would seem to be a very strong division of opinion both amongst the miners and the coalowners as to the acceptance of these proposals. At a special meeting of the Lancashire and Cheshire coalowners, held in Manchester on Tuesday, very strong opinions were expressed on the part of many of the colliery representatives that there had been too much concession to the demand of the Miners' Federation, and although the preponderance of feeling in the meeting was in favour of accepting the suggested terms of settlement, no really definite decision was come to, and another meeting of the coalowners of the district will have to be held before the Lancashire representatives on the Conciliation Board can be empowered to actually accept the proposed settlement. Much the same feeling exists amongst the miners of the district, and at a special conference of the Lancashire and Cheshire Miners' Federation held in Manchester on Wednesday, there was also a strong division of opinion upon the question, and any actually definite decision upon the matter was left over until the miners at their various pit-head and district meetings have had an opportunity of expressing their opinions, when probably another conference will, if possible, be held to decide upon what definite instructions shall be given to their representatives on the Conciliation Board. Notwithstanding, however, this strong opposition in some quarters on the part of both the coalowners and the miners against the proposed compromise for a settlement of the wages question, there is not much doubt that eventually it will be accepted, and conversing with a well-informed trades union official, representing an important branch of industry, which, although outside, is very appreciably affected by any disruption which may take place in the coal trade, he expressed the opinion that the Miners' Federation officials had made a very good stroke of policy in obtaining the suggested terms of agreement, and that the miners would be very ill-advised if, looking only at the present 10 per cent. reduction in wages, they refused to endorse the very important other concessions which the official leaders had been able to obtain from the employers. Amongst the more responsible official representatives of the miners the opinion is expressed that although not a few of the men might make a show of opposing any reduction whatever in wages, the proposed terms of settlement will in all probability be agreed to.

*Barrow.*—The past week has been a very quiet period in the hematite pig iron trade. There has been no increase in business nor any improvement in the general tone of demand. Makers are indifferently employed, and it is shown that although only thirty-six furnaces are in blast, makers are producing more iron than they can sell at present. The trade doing at the moment is more of a consumptive than of a speculative character. Makers still quote 44s. 6d. to 45s. 6d. for parcels of mixed numbers of Bessemer iron net f.o.b., and warrant iron is quoted at 44s. net cash sellers and 43s. 11d. buyers. During the week stocks have increased 2086 tons, and now stand in warrant stores at 149,852 tons, or 54,959 tons more than was in stock at the beginning of the year.

Iron ore is weaker, at 8s. 6d. per ton net at mines for ordinary qualities. Smelters in the district are only using small parcels.

Steel makers are short of work in most departments. Rails are in quiet inquiry, and makers are not in any sense well sold forward. Prices are easier. The demand for plates is quiet, but makers are fairly well off for orders. Tin-plate bars are only a quiet trade. Orders are scarce for blooms, slabs, wire rods, and billets, while hoops are exceedingly quiet.

Shipbuilders and engineers are busy in practically all departments, and it is obvious that for some considerable time to come there will be marked activity. New work is not, however, coming to hand as briskly as is desirable; but compared with other districts, Barrow is very well off for orders. Very little prospect of new tonnage is afforded, but it is believed one or two large specifications in the market will be fixed at Barrow.

Coal and coke are quiet, and in small consumption at late rates.

The shipping trade shows a slight improvement. There has been an increase in both pig iron and steel. The exports of pig iron during the week have represented 8300 tons from West Coast ports, compared with 5165 tons in the corresponding week of last year, an increase of 3135 tons. The shipments of steel last week were 10,269 tons, compared with 8431 tons in the corresponding week of last year, an increase of 1838 tons. The shipments of pig iron to date this year have reached 203,421 tons, compared with 138,033 tons in the corresponding period of last year, an increase of 65,388 tons; while the shipments of steel to date have reached 204,988 tons, compared with 247,835 tons in the corresponding period of last year, a decrease of 42,847 tons. Shipping freights are scarce, and are at low and unremunerative prices.

There is still a large number of skilled and unskilled artisans out of work.

## THE SHEFFIELD DISTRICT.

(*From our own Correspondent.*)

THE Scotch strike has so far had much less influence upon the South Yorkshire coalfield than was expected. It has, of course, caused the Northumberland and Durham coalowners to be very active, and their competition with the Yorkshire colliery proprietors has therefore considerably slackened. In that way the dispute has made values somewhat firmer, as well as prevented the falling off in the demand for household qualities, which would have happened in consequence of the present hot weather. The Yorkshire pits, in the thin seams, are working about three days a week. London is taking an average tonnage, and as North-country coal is not available in such large quantities, rather stronger quotations are ruling. London merchants, however, are able to oppose any substantial advance in prices. Silkstones make from 9s. 6d. to 11s. 6d. per ton; Barnsley House 8s. 6d. to 10s. per ton; other qualities from 8s. to 9s. 6d. per ton. Owing to a steady demand for export, as well as for supplies for railway furnaces, steam coal continues in brisk request, all the Humber ports receiving heavy weights, Barnsley Hards make from 7s. 9d. to 8s. 6d. per ton; other qualities from 7s. per ton. Gas coal averages from 7s. 6d. to 8s. 6d. per ton, with a consumption rather under the average. Manufacturing fuel but lightly ordered, owing to the depression in trade. Good slacks are from 4s. 6d. to 5s. 6d. per ton, smudge and small coal from 2s. per ton upwards. Little is doing in coke, quotations ruling from 9s. to 10s. 6d. per ton.

The Hull Chamber of Commerce, in its monthly return, shows that June has been a fairly good one for the Yorkshire collieries shipping at that port. The total weight for the month sent from 176 collieries has been 168,936 tons, as compared with 153,656 tons for June, 1893. For the six completed months the weight is 925,104, against 739,376. The South Yorkshire pits seem to have done exceptionally well. Eighteen of these collieries sent nearly 60 per cent. of the tonnage to Hull during the half-year, which is the largest amount for many years. Denaby Main again heads the list with 98,416 tons, followed by Carlton and Monk Bretton with 53,852 and 53,456 tons respectively. The exports to foreign countries were smaller than might have been expected during June, viz., 60,054 tons, as against 87,652 tons in June, 1893. For the six months, however, the exports reached a total of 297,500 tons, against 235,302 tons in the first half year of 1893. These figures show an increase of over 17 per cent. this year as against last year, and exhibit a recovery of 35 per cent. of the trade lost in the first half of last year, when the Hull Dockers' strike practically lost the larger portion of the business. The diminished exports are accounted for by a falling off in the demand from North Russia, which took only 15,788 tons last month, against 29,161 tons in June of 1893. Sweden and Norway took 23,337 tons, against 32,805 tons. Germany also shows a falling-off, while Holland and Denmark exhibit an increase.

The letting of gas contracts is going forward slowly. The colliery owners decided to demand an advance of 1s. per ton, but the decision of their organisation is considerably modified in the actual placing of orders. The contract for the Birmingham Corporation Gas Works has been settled at a very slight advance. The Leicester Corporation have taken an unusual, though acceptable course. Instead of putting the contract on the market in the ordinary way, they have offered the former contractors an advance of 6d. per ton. The offer has been accepted all round. Leicester last year was in the favourable position of obtaining gas coal at about the lowest prices which ruled that season.

In the heavy trades there is no change to report, and goods are only being ordered to meet immediate requirements. A fair quantity of tires, axles, springs, &c., are being produced for the Indian market. In crucible steel manufacturers report a good continental demand for best brands, but competition keeps down prices to the narrowest margin of profit. While the tendency of prices is thus downward, the tendency of wages is upward, and this makes it increasingly difficult for orders to be completed at a profit. The iron trade of the district is said to be benefiting slightly by the Scotch strike, the inability of Scotch ironmasters to take orders causing the inquiries to be made in this locality. Prices, however, have not yet been appreciably affected thereby. Any improvement in iron will necessarily operate favourably upon steel, and if the strike in the North continues local firms will undoubtedly profit. Quotations for hematites can scarcely be said to have changed for over a month. They remain at from 51s. to 52s. 6d., delivered in Sheffield. Common forge iron fetches 38s.; bar iron, £5 10s. to £5 15s.; common wire rods, £5 5s.; high carbon and rope rods, £8 8s.; ordinary iron sheets, £8 10s.; Bessemer billets—Sheffield made—are at £5 7s. 6d. to £5 10s. per ton delivered at the station; inquiries not up to the average.

The foreign trade in hardware and cutlery during June shows a considerable decrease, the value having been £148,428, against £176,574 during the corresponding month of last year. For the six months ending June 30th, the value was £900,852, against £1,043,711 for the first half of 1893. The increasing markets on the month are Russia, Holland, Belgium, France, and British Possessions in South Africa. The decreasing markets are Sweden and Norway, Germany, Spain and Canaries, United States, Foreign West Indies, Chili, Brazil, Argentine Republic, British Possessions in East Indies, Australasia, and British North America. In steel, unwrought, a slight improvement is reported for June, the value having been £165,473, against £164,508 for June of 1893; for the six months £891,527, against £853,312. Increases are shown by Russia, Sweden and Norway, Holland, France, British East Indies, and Australasia. The decreasing markets are Denmark, Germany, United States, and British North America.

The quarterly return of exports to the United States from the Sheffield Consular District grows increasingly serious. The total value for the three months ending June 30th reached only £73,315 16s. 10d., a falling off of £42,042, as compared with he corresponding quarter of 1893. There has scarcely been anything doing in cutlery, the total value sent during the three months being represented by £6518, against £27,780 in the three quarters of last year. This shows the enormous decrease of £21,262, or more than 75 per cent. The decline, of course, is entirely attributable to the uncertainty created by the proposed tariff changes. There is some hope of the new tariff coming into operation on the 1st of August. It will not be an unmixed blessing, for while several grades of cutlery may be reduced by 60 per cent. to 25 per cent., as compared with the McKinley Bill, in other qualities there will be a positive increase. The greatest relief will be in respect to the very cheap kind of pen and pocket knives which the Americans and Germans produce in the largest quantities. Our cutlery manufacturers state that stocks in America are now so low that as soon as the new Bill has passed there is certain to be a very brisk demand. On the other hand, the pressure which is expected has been considerably discounted by the different houses having been making for stock for some months. The exports of steel to the States last quarter amounted to £51,777 against £69,281 a year ago; thus showing a decline of £17,504. Under the Wilson Tariff the duty on steel will be reduced by several cents per pound. Files and hardwares generally will also be slightly relieved.

The Yorkshire miners have very readily paid the levy imposed upon them on behalf of the Scotch miners out on strike. The amount was 6d. per member, which realised a total for the county of £1250. This has been forwarded to the treasurer for the support of the Scotch miners. The Central Board of the Federation have resolved that the levy must be doubled, making the Yorkshire contribution £2500 per week. A circular has been issued by the officials of the Yorkshire Miners' Association, in which they urge that every member shall pay 1s. per week levy to help the Northern miners. They point out that if the Scotch miners are successful the English miners will be safe for a long time to come. "We know," add the Yorkshire officials, "this is a heavy burden, especially to those who are only working a few days per week, but it would be better to do this than to run the risk of something being taken off our wages. The Scotch leaders believe that if we can support them to the extent we have referred to that they will have victory on their side. We hope every member will pay his 1s. and every half-member his 6d. on Saturday in order to help the miners of Scotland to fight their battle."

## THE NORTH OF ENGLAND.

(*From our own Correspondent.*)

NO real improvement in trade in this district has yet taken place as a result of the Scotch strike, though the production of pig iron in Scotland has become very small, seeing that only eighteen furnaces are left in operation. No doubt there is less competition for orders from the Continent, and producers in this district are getting a larger share than usual, but this is counterbalanced by the falling off in the demands of the Scotch mills and forges for Cleveland pig, added to which local demands have considerably declined by reason of the moulders' strike in the North-East Coast shipyards and engineering works. Thus, on the whole, Cleveland iron makers are not so well off as they were last month, and the prospects are not encouraging, for the end of these labour difficulties is not likely to be yet.

What is most affecting trade in this district is the strikes of moulders and patternmakers, which have already lasted sixteen weeks. The effects are far-reaching, for while the number of men on strike is comparatively small, their action is throwing out of employment thousands of other men, as shipbuilders and engineers cannot get on further without castings, and the strikers prevent them as much as possible from obtaining these from other districts. They have, therefore, no alternative but to close their yards, and thousands of people are being punished because of the conduct of a few. Thus in Hartlepool there are only some 130 men directly on strike, but their action has thrown 4000 others out of work. The principal shipyards and engineering works in the Tees and Hartlepool districts are closed, and on the Tyne and Wear they are following suit. In addition to the yards mentioned in my last report as having been stopped, Messrs. R. Irvine and Co., West Hartlepool, have closed. Messrs. W. T. Doxford and Co., Pallion, Messrs. J. L. Thompson and Sons, North Sands, Sunderland, Messrs. C. S. Swan and Hunter, Walker, and Mr. James Laing, Sunderland, have also given their men notice. Messrs. William Gray and Co., of West Hartlepool, say their shipyard work is "three months ahead" of the work at the engine works, and that when the latter are again started it will be at least ten weeks before their shipyards can fully re-open. The dispute is causing a great curtailment of operations at the iron and steel works, because shipbuilders have been compelled to ask plate and angle makers to suspend deliveries, and it is impossible under present circumstances to secure other orders to replace them. This in its turn affects the hematite pig iron trade specially, and to a smaller degree the Cleveland pig iron trade, and we have easier prices for the pig generally used at the finished iron and steel works. The moulders express their determination, notwithstanding the suffering that is being caused, to continue the strike; but the masters are equally determined, as the present state of trade and future prospects justify a reduction rather than an advance. There was never—even at the very first—any justification for such an advance as the men demanded, viz., 10 per cent. on piece and 3s. 6d. on time wages; or even for the modified demand of 5 per cent. and 2s., which was made some time afterwards. The men asserted that there was a revival of trade, as a number of orders for vessels had been given out. But the employers were not of the opinion that a revival had set in, although there was undoubtedly an increase of work in some shops; but there was a reduction in others, and prices certainly had not improved. This view of the situation has proved to be correct, and time has shown that many of the orders were purely speculative ones, which have since been cancelled, or are not to be executed at once. If there were no justification for an advance four months ago there is less now. The improvement was a mere "flash in the pan." Yet having made their demand the men will not recede from their position, and refuse the offer of the masters to endeavour to settle the matter by conciliation, resuming work in the meantime at the old rates of wages.

Pig iron is in rather quiet demand, except that for No. 3 Cleveland it is better than it was, and in the hands of the makers that quality is decidedly scarce, as it has recently been wanted largely for shipment. Some producers during the past week were unable to load all the vessels sent to their wharves, and others being altogether out of stock have had to refuse orders for immediate delivery. There is plenty of No. 3 in the district, though it is not in makers' hands — it is in the public warrant stores, but buyers do not care to draw it out, because that might lead to the stock with Connal's decreasing, and it would cause prices to advance. It is surprising to note that while so much difficulty is experienced in getting No. 3 from the makers generally, the stock in the public warrant stores should be increasing. More business could have been done during the last ten days in No. 3, if makers had had it. The pig iron shipments from the Tees last week were almost the largest on record. They reached 34,605 tons, an average of 5767 tons per day, and on one day upwards of 8300 tons were shipped, while more could have been sent if the iron had been available, and there were more vessels waiting cargoes, and could not get up to the wharves. The exports last week were double those of the first week in June last year, and most of the iron was sent to the Continent, a very considerable proportion being hematite, which was despatched to Russia and Italy. The footing gained last year in Russia by our hematite ironmakers when that country and Germany were having their tariff war has not been lost now that the war is over. Exports this week are not on such a large scale as last week, partly because the deliveries to Scotland have been further cut down because the Glasgow Fair holidays have commenced, and the foundries, which have been working in spite of the strike are idle. Pig iron exports this month have reached 40,080 tons, as compared with 27,685 tons last month, and 23,886 tons in July, 1893, all to 11th. The stock of Cleveland pig iron in Connal's stores on Wednesday night was 99,182 tons, or 1151 increase this month.

The price of No. 3 Cleveland pig iron is well maintained, and not less than 35s. 6d. per ton for prompt f.o.b. delivery will be accepted, while some brands that are specially in demand for export have been sold this week for 36s. Cleveland warrants do not fluctuate much, because scarcely anyone will buy them at present, and the closing figure on Wednesday was 35s. 5d., which was 2d. less than the opening price. For the commoner qualities of Cleveland pig, such as are used at the mills and forges, the demand is smaller, partly because of the diminution in the Scotch requirements, and partly because the moulders' strike is causing a lessened consumption at the local finished ironworks. The supply is larger, the demand smaller, and prices weaker. No. 4 Cleveland foundry is quoted 34s. 9d., and grey forge 34s. 3d., for early f.o.b. delivery, but less has been taken, in some cases, even 3d. less. East Coast hematite pig iron is also cheaper; Mixed numbers having been sold at 43s. 6d., and in a few cases at 44s. 3d., as producers are very anxious to get orders now the steel plate and angle works are not doing so well.

The average realised price of No. 3 Cleveland pig iron during the quarter ended June 30th is officially certified to have been 35s. 5·61d. per ton, an advance of 5·78d. on the figure for the previous quarter, and wages at the blast furnaces for the current quarter will be advanced ·75 per cent. — ¾ths of 1 per cent. The men have given the requisite notice for the termination of this sliding scale. The Cleveland blast furnacemen have voted by a very large majority—2600 against 121—to give a legal notice for a proposed twenty-four hours' stand, so that they may hold a demonstration at Middlesbrough, on August 6th, on the eight hours' question. If a stand takes place it will be actually for sixty hours.

Trade is very quiet in the finished iron and steel industries, and prospects are not encouraging. The Scotch shipbuilders are sending a few more orders for plates and angles, which they cannot now procure from native works, but there is a heavy falling off in the number of those received from the shipyards on the North-East Coast, and in many cases the execution of orders already booked is suspended until the yards reopen after the settlement of the moulders' strike. Steel ship plates can be bought at £4 17s. 6d.; steel boiler plates at £5 17s. 6d.; steel ship angles at £4 15s.; iron ship plates at £4 15s.; iron angles at £4 12s. 6d., and common iron bars at £4 17s. 6d., all less 2½ per cent. and f.o.t. Heavy steel rails are quoted £3 12s. 6d. net at works, but trade is very bad.

The Darlington Steel and Iron Company, which produces chiefly rails, reports a loss for the year ended April 30th of £3571 14s. 2d., and not only the ordinary, but also the preference, shareholders will get no dividend. In the previous year the profit was £5121, but no preference dividend was paid, as it had been paid the previous year out of reserve, when there was a loss of £1474. In

1891 a profit of £10,890 was made; in 1890, £3595; and in 1889, £7422.

Both Northumberland and Durham are sending considerable quantities of coal to Scotland, and the exports oversea are good, Sunderland shipping over 90,000 tons and Tyne Dock over 120,000 tons of fuel, both being considerably more than at the corresponding period last year. Last month from the north-eastern ports 1,552,040 tons of coal were shipped, or 147,345 tons more than in June, 1893. The moulders' strike is affecting the coal trade, local consumption being smaller. But Northumberland steam coal is 11s. per ton f.o.b., and small, 5s. It has been officially ascertained that the realised price of Northumberland coal during the three months ending May 31st was 6s. 4·72d. per ton, but there is no sliding scale now. However, a Conciliation Board has been formed, and Mr. John Strachan, barrister, London, has been chosen as Chairman of the Board, the first meeting of which will be held on the 24th inst. Messrs. Ernest Scott, Mountain and Co., Newcastle, have completed the electric pumping plant for Messrs. Straker and Love's Brancepeth Colliery, near Durham. In connection with the colliery to which the plant is to be applied, there is a scarcity of water for the working power of the pit, and the new pumps are to draw a supply from an adjoining body of water, and convey it to the colliery. The distance of the pumps from the generating dynamo will be about 700 yards. The pumping plant is capable of delivering 300 gallons of water per minute through two miles of 6in. pipe, against a head of 250ft. Owing to the friction in the pipes this equals a total head of 410ft. The installation consists of a set of three-throw ram pumps of Scott and Mountain's improved mining type, driven by an electric motor of 55-horse power effective. The dynamo is driven by a horizontal steam engine, developing 80-horse power.

The Scotswood Shipbuilding Yard, on the Tyne, was almost totally destroyed by fire on Saturday afternoon last, and it is believed the fire was started by an incendiary. The yard is situated close to the suspension bridge, and was the first place of the kind commenced on the Tyne above the Swing Bridge at Newcastle. It was originally in the hands of a Scotch company, but afterwards passed into the hands of the Scotswood Shipbuilding Company; practically a branch of a firm in Brazil, who carry on traffic on the great South American rivers, and who took the Scotswood Yard for the purpose of building their own boats.

Mr. C. P. Douglas, the chief of the engineering and designing staff at the Consett Iron and Steel Works, has resigned, and is retiring into private life.

## NOTES FROM SCOTLAND.

(*From our own Correspondent.*)

THE Glasgow pig iron market has been very quiet this week. Small quantities of Scotch warrants have changed hands at about former prices. For Cleveland iron scarcely any demand has been experienced, and there has been nothing doing in hematite. Indeed, the market is quite disorganised by the strike and by the annual trade holidays which are just beginning, and are likely to be of longer duration than usual.

The strike of the miners is regarded in commercial circles as altogether unjustifiable. From the coalmaster and ironmasters' point of view it is wanton in the extreme, the miners having been in receipt of good wages when they were brought out by the Federation. The object of the leaders of the miners is to compel a certain wage, altogether irrespective of the state of trade, and the unanimity with which ironworks and factories have been closed is evidence of the determination of consumers to resist attempts to raise the price of fuel artificially above what is justified by the condition of trade.

Since last report a number of additional furnaces have been put out of blast, including five at Gartsherrie, which is now quite black, the whole of the twelve furnaces there being silent. Messrs. Wm. Baird and Co. have at Gartsherrie and their other works twenty-eight furnaces in all, and only four of these remain in blast, two at Muirkirk and two at Lugar. There are now only eighteen furnaces blowing in Scotland, compared with forty-nine last week and seventy at this time last year.

Special brands of makers' iron are in a number of cases becoming scarce. The prices are advancing. G.M.B. f.o.b. at Glasgow No. 1 is quoted 43s. 6d. per ton; No. 3, 42s. 6d.; Monkland No. 1, 44s.; No. 3, 42s. 6d.; Carnbroe No. 1, 46s.; No. 3, 44s. 6d.; Clyde No. 1, 51s. 6d.; No. 3, 48s. 6d.; Summerlee No. 1, 52s. 6d.; No. 3, 48s. 6d.; Calder No. 1, 53s. 6d.; No. 3, 48s. 6d.; Gartsherrie No. 1, 53s. 6d.; No. 3, 49s.; Coltness No. 1, 55s. 6d.; No. 3, 50s. 6d.; Glengarnock at Ardrossan No. 1, 52s.; No. 3, 48s. 6d.; Eglinton No. 1, 49s.; No. 3, 44s. 6d.; Dalmellington at Ayr No. 1, 47s. 6d.; No. 3, 45s.; Shotts at Leith No. 3, 51s.

The shipments of pig iron from Scottish ports in the past week were 5646 tons, compared with 6847 in the corresponding week of last year. There was despatched to Canada 300 tons, South America 5, India 196, Australia 150, France 25, Italy 45, Germany 732, Russia 400, Holland 375, Belgium 50, Spain and Portugal 10, other countries 115, the coastwise shipments being 3244, compared with 4197 in the same week of 1893.

The market for manufactured iron and steel is very flat, transactions being few and unimportant, and prices nominal. The iron and steel manufactured goods shipped from Glasgow embraced locomotives worth £3880, sewing machines £16,766, other machinery £15,634, steel goods £10,553, and miscellaneous iron goods £11,350.

There has been a sweeping reduction in the coal export trade. The clearances from the whole of the Scottish ports in the past week amount to only 24,849 tons, compared with 153,968 in the corresponding week. Only two weeks ago the shipments were 154,200 tons, so that the collapse has been very severe. Merchants are purchasing very little, and only to meet the most urgent requirements. The home consumption is also rapidly falling away; prices are irregular.

## WALES AND ADJOINING COUNTIES.

(*From our own Correspondent.*)

SEVERAL more bodies have been brought up from the Albion Colliery, and the total loss up to date is 282. Several hundred men are busily employed in clearing away the falls, and in another week or two a resumption of work will take place.

Next week the inquest will be re-opened before the two coroners of both divisions, and a most exhaustive investigation is certain. It is not yet stated who will be sent down by the Home-office; in fact, all details are lacking, and only surmises are discussed as to cause. It was stated a few days ago that an unlocked lamp had been found among the rubbish. Up to the explosion, and to the last visit of the firemen, the condition of the colliery was certified as excellent, and thus it is one of the remarkable suggestions of the scientific world that a large cavity, holding a great quantity of gas, had been accidentally struck into, and this only needed the accidental or rash exposure of light to cause the disaster. Against these things the best skill and caution are useless. Old colliers say that there are constant movements going on in the earth, known as squeezings, and if these are not uniform, say above, cavities would be formed just above the roof, and beyond the action of ventilation, into which gas would exude and remain until broken into. The explosion has brought the subject of electric lighting of mines to the front, and no doubt the thorough adoption of the electric light will do much good.

The steam coal trade continues thoroughly active, and will in all probability continue so for some time. At the Exchange, Cardiff, a few days ago, the impression was strong that, so far, the Scotch strike had not affected the Welsh market, but that the buoyancy of the coal trade was due to the demands for the fleet, and to the withdrawal of the Albion coal from the market. This, I need scarcely say, was not the general view, and it would be a difficult if not an impossible task to substantiate it. In a few weeks again, should the normal sagacity of the Scotsman still remain under a cloud, a better opinion can be given. This is certain, that in all previous strikes in England, there has always been a beneficial reaction in Wales. Several cargoes of 4000 tons were cleared from Cardiff on Saturday last, and quite a numerous fleet with coal consignments ranging between two and three thousand tons.

As may be inferred, the export of coal at all ports continues above the average. Cardiff and Newport show large totals, and at Swansea last week the total was 37,699 tons. During the last six months the total export of coal from Swansea amounted to no less than 171,142 tons over the corresponding period of 1893. Best steam coal at Cardiff this week was in firm demand at 12s. to 12s. 6d., and even seconds were proportionately high. Quotations for best seconds were 11s. 6d.; inferior kinds, 10s. 6d. to 10s. 9d.; small, 6s. 6d. to 7s.

House coals have dropped a little since the beginning of the week. On Saturday quotations for best were 12s. to 12s. 6d., but mid-week best households could be bought at 11s. to 11s. 3d. No. 3 Rhondda remains at 10s. 9d. to 11s.; brush, 9s. to 9s. 3d.; small, 7s. to 7s. 3d.; No. 2, 9s. 6d. to 10s.; through, 7s. 6d.; small, 5s.

Prices of coke remain good, furnace selling at 15s. 6d. to 16s.; good foundry, 17s. 6d. to 18s.; and best foundry, 20s. to 20s. 6d. Pitwood is at 14s. 9d. All these quotations are Cardiff. Iron ore is selling at the following prices:—Porman, 10s. 9d. to 11s.; Tafna, 11s. to 11s. 3d.; Garncha, 11s.; best Rubio, 11s. 6d. to 11s. 9d. Patent fuel continues in good demand, Cardiff and Swansea.

The week has been unusually brisk with iron ore cargoes; the Dowlais Company received four, Cyfarthfa two of large tonnages, 2100 tons came in for Ebbw Vale, close upon 4000 tons for Blaenavon, and two large cargoes for Tapson and Sons. The inference on 'Change is that if no substantial rail orders are in prospect, it is probable that there will be increased vitality in the tin bar trade.

There was an average steel make at the principal works last week, and I was pleased to note, both on the Rhymney and Taff Vale Railway, at the close of last week a marked increase in the rail trucks, which formerly figured almost as briskly as coal wagons. But those were the days when consignments from Dowlais and Cyfarthfa to America and Russia were constant, and now in the matter of rails each is "self-supporting." There is some expectations of foreign orders for rails and sleepers. All iron and steel quotations are practically the same as last week at Cardiff.

It is now tolerably certain that a good spurt in the tin-plate trade is near at hand. The definite announcement that the reduced rates under the new tariff in America will come into force on the 1st of August has quickened expectation in the Swansea district, and this week, on 'Change, it was announced that six steamers for the States and two for Canada are now due, or will be in a few days.

Last month the total export of tin and black plate for the United States amounted to 12,602 tons, and for Russia 1687 tons. The improvement in the Russian trade is shown by the fact that in June, '93, the export was only 280 tons.

There has been no change in tin-plate prices since last week, but an improvement can be depended upon, and those who have secured forward delivery are fortunate. Most of the business is hand to mouth. Tin-plate shipments last week from Swansea amounted to 45,169 boxes only, receipts from works 58,812 boxes. Stocks now amount to 287,245 boxes.

From Harrington last week, Swansea received 419 tons tin-plates, and 440 tons pig iron, and from Ulverston 600 tons pig iron. I instance this to show the vigorous competition going on between England and South Wales.

On 'Change, Swansea, mid-week the following quotations ruled:—Glasgow pig, 42s.; Middlesbrough, 35s. 6d.; Middlesbrough hematite, 43s. 1½d.; Welsh bars, £5; sheet iron, £6 5s. to £6 10s. at works; steel the same, with extras for the higher gauges. Bessemer steel: tin plate bars, £4 to £4 2s. 6d.; Siemens, best, £4 2s. 6d. to £4 5s; second, £4 to £4 2s. 6d., all delivered in the district, less 2½. Tin plates: Bessemer steel cokes, 10s. 4½d. to 10s. 6d.; Siemens, 10s. 6d. to 10s. 9d.; best charcoal, 11s. 9d. to 12s. 9d., according to finish and brand. Wasters, 6d. to 1s. less than primes. Old sizes, usual extras. Ternes, 28 × 30, 20s. to 23s. All tin plates delivered in Prince of Wales' dock, Swansea, cash, less 3 and 1 per cent.

Other Swansea quotations this week are:—Anthracite coal, 8s. 9d. to 9s. 6d., according to quality; coke, 4s. 9d. to 5s.; steam coal, 10s. to 11s. 6d.; seconds, 9s. 6d. to 10s.; bunkers, according to quality, 7s. 6d. to 10s.; small, 5s. to 5s. 6d.; bituminous coal, No. 3 Rhondda, 11s. to 11s. 6d.; small, 7s. 6d. to 7s. 9d.; coke, furnace, 12s. to 12s. 6d.; foundry, 17s. 6d. to 18s.; patent fuel, 10s. to 10s. 9d.

Last week, Swansea despatched 700 tons patent fuel to France, 1160 to Spain, 1750 to Russia, 1100 to Italy, 1200 to Roumania, and 1400 to Algeria.

Mr. Preece, the chief of the electric telegraph department, G.P.O., London, gave an interesting address at the National Eisteddfod, Carnarvon, this week, on "The Industrial Condition of Wales," touching especially on the mineral development of the country, and corresponding improvement in docks and railways. As it will be republished, I only refer here to the successful way in which the subject was treated. In coal details there was a reference to the originator of the steam coal trade, Mrs. Lucy Thomas, with her level and barge, and the vast growth which has followed her output of a few tons daily.

Twelve million tons of coal now, according to the historians of the Welsh coal trade, are exported from Cardiff alone annually, and the army of coal workers totals close upon 90,000 men and boys.

I am glad to note that the Bute Docks Bill, one of the latest and greatest, by the efforts of Sir W. T. Lewis, is now an accomplished fact.

One gets an insight into the profits of collieries, and at the same time learns the cost of a strike by the published reports of large companies. I have the report of the Abercarne Coal Company before me for the year ended March 31st, 1894. This colliery, it will be remembered, was the scene of the greatest colliery accident that has ever happened in Wales—up to the date of the Albion, which has eclipsed it. The total output for last year was 490,944 tons, and the profit was £8813 10s. 9d. But the report states that the smallness of the profit was due to the strike—which occurred in August and September last—which kept the colliery idle for four weeks, and diminished the output for several months. The estimated cost of the strike was £5461 3s. 10d., which the directors have written off the reserve fund. The amount available for dividend was £9178 0s. 3d., and the directors recommend a dividend of 6 per cent. on the preference shares, and 3 per cent. on ordinary. Mr. J. Green, who has been the manager of the colliery since the commencement, has resigned—to the great regret of the directors, who have appointed Mr. Snape, of the Dowlais Collieries, in his place.

Details of a colliery strike has reached me from Caeran, Maesteg, where the regular workmen have been replaced by so-called blacklegs. A little while ago the men on strike cruelly assaulted the new comers, but the ringleaders were arrested, and on Monday, at Bridgend Petty Sessions, ten of them were committed for trial to the Quarter Sessions.

Another body has just been recovered from the Thorfa Colliery, the result of the great explosion which has now almost been forgotten in the disasters of Park Slip, Llanerch, and the Albion.

It is proposed to spend £7000 at Newport, Mon., building, &c., in connection with technical education. This busy port is exhibiting a good deal of vigour. The tender of Mr. J. Young, Glasgow, £94,596 2s. 4d., has been accepted in carrying out the new waterworks.

Cardiff population has increased 8000 since last year.

## NOTES FROM GERMANY.

(*From our own Correspondent.*)

TOLERABLY good accounts can be given of the general iron trade over here, though demand in some departments is not quite so brisk as during former weeks, and prices have in a few instances become easier.

Since last week there is no change to note with regard to the situation of iron business in Silesia. In pig iron a moderate demand is experienced generally, forge pig being in quiet request while in foundry pig only a poor business is being put through. There are decidedly more sellers than buyers, users of pig iron holding back from purchasing more than is absolutely necessary, in the expectation of still lower prices. The position of the finished iron makers is likewise not a favourable one, although they have a moderate weight of work to keep them going for some time ahead; but there is extremely little new business coming forward, and quotations are pointing downwards, so that the immediate outlook is anything but satisfactory. Plates are in very limited request, while sheets have been a trifle more animated this week than last. Steel manufacturers report themselves only insufficiently employed; rails especially are a poor business just now, the few orders that are being secured here and there leaving no profit. The Austro-Hungarian iron trade remains very much as last reported, makers booking a fair amount of new work at satisfactory quotations. Especially bars and plates and the different sorts of structural iron meet with a good demand, while rails are very quiet in tone, with little prospect for improvement in the near future. The hardware manufacturers report themselves well employed, the business done on local account being particularly lively at present.

A normal business continues to be done on the French iron market. Most sorts of pig iron are well called for, and the blast furnace works are quite actively engaged on home and foreign account. For all sorts of manufactured iron there is a fair demand experienced, and makers are hardening a little in their prices. In the steel trade a continued activity is reported, good employment being secured for many weeks to come; an order for 100 locomotives has recently been given out, while fresh contracts for locomotives are still announced. In Paris merchant bars still continue to be quoted 155f. p.t.; while girders can be had at 165f. p.t.

Belgian iron trade is still without improvement. There is very little new work offering; the few orders that are actually secured after a keen competition with German and English firms yield no profit. Forge pig, for instance, has been selling at 37·50f. p.t. The steel trade is reported to be very dull; indeed, some establishments are barely kept going for want of new work. With regard to the Rhenish-Westphalian iron market, affairs in the various districts remain very much as last reported.

Iron ore is in moderate request at unchanged quotations, spathose iron ore still fetching M. 7·40 to 7·90 p.t.; roasted do., M. 11 to 11·50 p.t., while inferior sorts range according to quality from M. 9 to 11·20 p.t. net at mines. For Luxemburg-Lorraine minette, 40 per cent. contents, M. 3·20 to 3·30 p.t. is given, inferior sorts not realising more than M. 2·40 to 2·70 p.t. at mines. For pig iron there have been very few inquiries at all stirring, and although generally quoted rates remain unchanged, sellers, in most cases, have to offer substantial concessions where an order of some importance is concerned. Until now production has kept pace with consumption, so that stocks do not show an increase upon previous months. In the Siegerland small orders for pig iron are pretty numerous, and quotations have been comparatively firm. Spiegeleisen, 10 to 12 per cent. grade, fetches M. 52 p.t.; Rhenish-Westphalian forge pig is in moderate call at M. 46 to 47 p.t. for No. 1, and M. 40 p.t. for No. 3. Siegerland, good forge quality, is to be bought at M. 44 to 45 p.t. Hematite fetches M. 63 p.t.; foundry, No. 1, M. 63; No. 3, M. 54 p.t. Basic is still sold at M. 45 p.t., while for German Bessemer M. 49 to 50 p.t. at works is given. Luxemburg forge pig costs 48f. p.t., free Luxemburg. Upon the week but few inquiries have been coming in for most sorts of manufactured iron. Prices show a want of firmness, which is likely to increase if buyers continue to hold back with their orders as they do now. Bars are in languid demand, home requirements being but small at this time of the year. On foreign account next to nothing has been done for many weeks past. Girders are, on the whole, in fairly good request. In the hoop trade a pretty firm tone has manifested itself lately, and there have been contracts booked up to end of the year. The demand for plates is regular, but prices remain unfavourable, in many instances scarcely covering the cost of production. Pretty much the same can be told of sheets. The wire trade continues extremely dull, with prices unchanged, and there is also not much business done in rivets. Foundries and wagon factories are fairly active on the whole, but there is very little gained at the present quotations. The following may be considered as latest list quotations per ton at works:—Good merchant bars, M. 110 to 110; angles, M. 120; girders, M. 90 to 95, free Burbach; hoops, M. 113 to 120; billets, in basic and Bessemer, M. 81; heavy plates for boiler-making purposes, M. 150; tank ditto, M. 130 to 140; steel plates, M. 125; tank ditto, M. 115 to 120; sheets, M. 140; Siegen thin sheets, M. 130; iron wire rods, M. 115 to 120; drawn wire in iron or steel, M. 105 to 120; wire nails, M. 125; rivet iron, M. 130; rivets, good merchant quality, M. 150 to 155; steel rails, M. 112 to 115; steel sleepers, M. 106; fish-plates, M. 115; complete sets of wheels and axles, M. 270 to 280; axles, M. 220; steel tires, M. 215 to 230; light section rails, M. 95.

Herr Krupp, of Essen, has to pay the highest taxes in the district—Düsseldorf, Essen—having this year stated his income to amount to M. 7,190,000, against M. 6,000,000 in the year previous.

Output of coal in the mining districts of Dortmund was in 1893: 38,615,640 t., against 36,847,146 t. in 1892, and 37,398,561 t. in 1891, which shows production in 1893 to have been higher by 1,768,464 t., or 4·80 per cent. than in the year before. The number of men employed was at the end of 1893 150,386, against 144,328 at the same period in 1892, showing an incease of 6058. In 1893 32,464,250 t. coal and coke were sent by rail from the Rhein and Ruhr district, against 30,678,260 t. in 1892, and 23,203,110 t. in 1891, export in 1893 showing an increase of 1,785,990 t. against that of the year before. From Duisburg Harbour 1,116,997 t. were shipped in 1893, against 1,161,610 t. in 1892, and 1,046,513 t. in 1891; shipments from Ruhrort Harbour were 3,114,100 t. in 1893, 3,040-576 t. in 1892, and 2,779,532 t. in 1891; total shipments being 4,231,101 t. for 1893, 4,202,186 t. for 1892, and 3,826,045 t. for 1891. Of the coals shipped from Duisburg, 225,157 t. went to Holland, against 188,080 t. in 1892; to Belgium, 44,518 t. were exported, against 19,223 t. in 1892; while 847,323 t. were shipped from Duisburg to the Upper Rhine. From Ruhrort 1,232,105 t. were shipped to Holland, against 1,286,209 t. in 1892; to Belgium, 202,830 t., against 245,832 t. in 1892; and to the Upper Rhine 2,796,166 t., against 1,508,535 t. in 1892.

## AMERICAN NOTES.

(*From our own Correspondent.*)

NEW YORK, July 5th, 1894.

THE business world on this side of the Atlantic sees prospects for an early and general improvement in trade and manufacturing as a result of the end of the tariff agitation. The despondency of the past six or twelve months is beginning to wear off. Stocks of all manufactured products have practically disappeared. Wages have declined 15 to 20 per cent., as compared to two years ago. Further reductions will be announced as soon as the Tariff Bill is signed, if its figures demand. Those who are behind the scenes know there are a few serious obstacles still in the way to its passage. A very large amount of capital is ready for investment in many channels of industrial and commercial activity, but a start will not be made just yet. Railroad managers have roads and bridges to build, equipments to buy. Prices are low and attractive, but a conservative policy will be adhered to. Steel billets are 19·50 dols.; steel rails, 24 dols.; forge iron, 11 dols.; No. 1 foundry, 12 dols.

## THE PATENT JOURNAL.

*Condensed from "The Illustrated Official Journal of Patents."*

### Application for Letters Patent.

*** When patents have been "communicated" the name and address of the communicating party are printed in italics.

*27th June*, 1894.

12,427. Devices for Fastening Gloves, G. Enderby, Leicester.
12,428. Machines for Riveting Boots, E. W. Ward, Leicester.
12,429. Water Gauges, C. Billington, sen , and J. Newton, Staffordshire.
12,430. Carbon Printing, W. T. Watson and J. W. Woodifield, Hull.
12,431. Hot Air Mineral Inhaler, T. S. Atkinson, Dublin.
12,432. A New Medicinal Compound, P. R. Reid, Dublin.
12,433. A Trousers Suspender, B. Marwood, London.
12,434. Driving Gear of Cycles, P. McDowall, Glasgow.
12,435. Seats of Vehicles, J. T. Clark and W. Georgeson, Glasgow.
12,436. Cutting Cheese, W. Hayes and S. Wilson, Birmingham.
12,437. Pneumatic Tires, A. M. Hart and A. Smith, Manchester.
12,438. Bands for Curtains, J. Jackson and W. Alexander, London.
12,439. Slide Valves of Steam Engines, J. Illingworth, Halifax.
12,440. Mechanical Feeders for Openers, H. A. Corrigan, Manchester.
12,441. Ladies' Collarettes, S. Robinson, Snaresbrook.
12,442. Stop-motions for Looms, J. Vickerman, Stroud.
12,443. Looms, Mails, and Heralds.—(*Chaize Frères, France.*)
12,444. Displaying Articles, R. R. Beard, Birmingham.
12,445. Hair Curlers, D. Hone, Birmingham.
12,446. Pneumatic Tires, T. Pickin, Manchester.
12,447. Driving Gear for Cycles, G. L. Scott, Manchester.
12,448. Winches, J. Hastie, Glasgow.
12,449. Vegetable Squeezer or Press, W. R. Hall, Stafford.
12,450. Boots and Shoes, W. and J. H. Stafford, Manchester.
12,451. A Lever Spanner, I. Carruthers, Hove.
12,452. Oil Lamps and Glasses, C. F. A. H. Bagot, London.
12,453. Dress and other Guards, H. S. Phillips, London.
12 454. Weaving Pile Fabrics, J. and J. Muir, Glasgow.
12,455 Railway Vehicle Coupling, C. H W. Relyea, J. R. Sutton, and B. Wilbur, London.
12,456. Hoist for Kitchen Utensils, O. J. Baldwin and J. H. Sandstrom, London.
12,457. Spring Socket for Doors, B. W. Heymanson, London.
12,458. Packing Ring for Pistons, W. Lockwood, London.
12,459. Manufacture of Buckles, T. and W. Evans, Birmingham.
12,460. Cycle Saddles, J. E. Noirit, Birmingham.
12,461. Straw Bruising Apparatus, F. H. Livens, Lincoln.
12,462. Horse Rakes, G. E. Rowf, London.
12,463. Steam Engine Govenors, F. W. Wheadon, London.
12,464. Non-exhaustive Power, T. Cooper, Wa'sall.
12,465. A Bust Ring, S. B. Price, Birmingham.
12,466. Coal-dust Furnaces, P. Stiens, London.
12,467. Coke-ovens, A. J. Boult.—(*Franz J. Collin, Germany.*)
12,468. Braces, Bitstocks, W. P. Thompson.—(*Albert Brehm, Germany.*)
12,469. Incandescent Burners, C. Hatry, Liverpool.
12,470. Crates, Boxes, &c., O. Smith, London.
12,471. Reversing Gear for Engines, R. Thornewill and A. Davies, Liverpool.
12,472. Purses, &c , W. P. Thompson.—(*Carl Bauer, Germany.*)
12,473. Hose-coupling for Brakes, A. Wegmann, Liverpool.
12,474 Brakes and Foot-rests for Cycles, J. R. Stoney, London.
12,475. Ejecting the Water of Condensation from Steam Pipes, J. Murrie, Glasgow.
12,476. Electrical Switching Apparatus, J. S. Raworth, London.
12,477. Head Rests for Chairs, W. H. and C. J. Ash.—(*Alexander McGowan Denham, Chili.*)
12,478. Safety Pins, W. Briggs, London.
12,479. Machinery for Seamless Steel Tubes, R. Wootton and F. H. Griffiths, Birmingham.
12,480. Ribbon, G. C. Franklin, Birmingham.
12,481. Heat Indicating Apparatus, F. W. Golby.—(*F. H. and J. G. Hams, Germany.*)
12,482. Folders, F. Lione, London.
12,483. Electric Batteries, C. P. Shrewsbury, F. L. Marshall, J. Cooper, and J. L. Dobell, London.
12,484. Steels for Wearing Apparel, Theiler and Schneeli, London.
12,485. Programme for Advertising, C. Jack, London.
12,486. Elastic Fabrics, D. Young.—(*A. Straus, United States.*)
12,487. Petroleum Apparatus, R. P. G. Cornilleau and J. B. F. Guedon, London.
12,488. Tea Packets, S. Topley, London.
12,489. Fluids to Destroy Germs, R. J. White and W. Habgood, London.
12,490. Fish-hook Case, N. C. Lindsay and H. Stanbridge, London.
12,491. Cartridge, N. C. Lindsay and H. Stanbridge, London.
12,492. Electric Lamps, W. U. Hilliar, London.
12,493. Horseshoe Pads, P. A. Newton.—(*P. H. M. B. de la B. C. P. de Beaumont, France.*)
12,494. Punching Machine, F. and F. Squire, jun. London.
12,495. Sketching-box, H. H. Young, London.
12,496. Engine Governors, A. S. F. Robinson, London.
12,497. Purifiers for Wheat, J. Beal, London.
12,498. Shelves for Book Cases, H. Schulz, E. Strubel, and F. Idler, London.
12,499. Bolt Cutters, W. H. Beck.—(*W. L. Dutcher and P. D. Randall, United States.*)
12,500. Brick Presses, A. Rousseau, London.
12,501. Cigarette-making Machines, A. L. Munson, London.
12,502. Applying Oil to the Surface of the Sea, J. Behrmann, London.
12,503. Production of Effervescent Beverages, R. Wichmann, London.
12,504. Production of Haemo-gloain, A. Hommel, London.
12,505. Arc Lamps, J. J. Rathbone and A. Chester, London.
12,506. Cooling and Heating Apparatus, H. Marx, London.
12,507. Bicycle and Vehicle Gearing, W. T. Sudworth, London.
12,508. Plug Checks for Boilers, H. H. Lake.—(*J. H. Crosby, United States.*)
12,509. Vessel Propelling Apparatus, H. C. Vogt, London.
12,510. Electricity Supplying Apparatus, E. Chabeault, London.
12,511. Driving Gear of Cycles, E. G. Sheward, London.

*28th June*, 1894.

12,512. String Holding Stump for Hops, R. Fuller, Hawkhurst.
12,513. Steam Traps, W. Jeffery, Bradford.
12,514. Appliance for Picking Fruit, &c., T. Douglas, Glasgow.
12,515. Rowlocks, A Walker, Glasgow.
12,516. Printing and Perforating Machines, D. Carlaw, Glasgow.
12,517. Photographic Dark Shutter, A. A. Overend, London.
13,518. Rim for Fixing Pneumatic Tire, W. L'Estrange, Manchester.
12,519. Fishing Reels, E. West, Nottingham.
12,520. Engine Piston, J. A. Ewins, Birmingham.
12,521. Sliding Lid Cylinder, T. Johnson, Dudley.
12,522. Self-closing Cycle Mudguard, G. Pearsall, Smethwick.
12,523. Glass Advertising Tablets, W. A. Leadbetter and J. W. Blackham, Birmingham.
12,524. Sheet Suspender, H. Lane and F. W. Witcomb, St. Leonards-on-Sea.
12,525. Attaching Door Knobs to Spindles, C. J. Whitehall, Nottingham.
12,526. Fluid-pressure Brakes, J. G. A. Kitchen, Manchester.
12,527. Boxes, T. Kay, Glasgow.
12 528. Pans, W. W. Percival, Bradford.
12,529. Corkscrew, W. R. Maud, Pontefract.
12,530. Double Hoops for Railway Springs, J. Duce, Sheffield.
12,531. Means for Locking Bicycles, J. Everard, Birmingham.
12,532. Bicycles, J. Hargreaves, Manchester.
12,533. Coal Tipping Wagons, S. Thomas, J. L. Powell, and C. T. Batchelor, Penarth.
12,534. Coal Tipping Wagons, S. Thomas, J. L. Powell, and C. T. Batchelor, Penarth.
12,535. Splinter Bars for Vehicles, R. W. Crichton, Stewartstown, Co. Tyrone.
12,536. Adding Machine, G. Mahlstadt and C. F. G. Kopech, Woking.
12,537. Prime Movers, J. Joyce and S. H. Berry, London.
12,538. Office-return Indicator, J. Woolf, London.
12,539. Shirt-starching Machinery, H. T. Tallack.—(*A. M. Dolph, United States.*)
12,540. Cycle Mudguard, T. McEleny, Glasgow.
12,541. Measuring Alternating Currents, F. H. Nalder, C. W. S. Crawley, and A. Soames, London.
12,542 Tongs or Irons for Curling Hair, A. Morton, London.
12,543. Window Sash Fastenings for Opening In, J. Urie, Pollokshaws.
12,544. Postal, &c., Cards, H. Rowe and J. Clayton, Leeds.
12,545. Shoulder Straps and Appendages, G. H. Smith, London.
12,546. Dust-proof Watch, W. Harris, London.
12,547. Pneumatic Suspension Seat, W. M. Higgs, London.
12,548. Nut Lock, N. Barnes, London.
12,549. Cables for Telephonic Purposes, M. Immisch, London.
12,550. Shooting Gallery, F. H. Urry, J. Price, and G. Haydon, London.
12,551. Spraying Apparatus, A. J. Boult.—(*E. Hochheim, Germany.*)
12,552. Protecting Electric Cables, G. H. Nisbett, Liverpool.
12,553. Automatically-releasing Chains, W. A. Thornton, London.
12,554. Working Annular Kilns, W. P. Thompson.—(*F. Schofer, Germany.*)
12,555. Ratchet Braces, F. A. Willmott, C. W. Cobon, and J. Driscoll, London.
12 556. Cycles, E. J. Newell and J. Hodson, London.
12,557. Luminous Electric Skipping Rope, G. Trouvé, London.
12,558. Stand for Bicycles, T. F. and S. E. Spencer, London.
12,559. Disinfecting Drain Ventilator, L. D. Milnes, Norwich.
12,560. Device for Holding Lengths of Cane, G. Horide, London.
12,561. Boat Seat, W. Jardine and W. A. Jardine, London.
12,562. Spinning Tops, H. Browne, London.
12,563. Developing Tank, W. Rigg and P. Raymonds, London.
12,564. Advertising, J. W. Hurst, London.
12,565. Buckle for Traces, W. Silver and S. Sinauer, London.
12,566. Dust-proof Electrical Switch, A. E. Williamson, London.
12,567. Bungs, T. C. Barraclough and T. T. Heaton, London.
12 568. Attachment for Umbrella Ends, J. Smith, London.
12,569. Railway Rolling Stoch Wheels, F. Smith, London.
12 570. Boot or Shoe Holding Device, E. Leger, London.
12,571. Puzzle Game, J. Ritchie, London.
12,572. Optical Lanterns, H. C. Newton, London.
12,573. Manufacture of Cartridges, D. M. Hawes, London.
12,574. Inkstand, A. Hradil, London.
12,575. Tunnel Constructing Appliances, P. Kraus, London.
12,576. Convertible Box, R. R. von Gryra-Morawski, London.
12,577. Manufacture of Compressed Tea Tablets, The Military Equipment Stores and "Tortoise" Tents Company and A. S. Tomkins, London.
12,578. Attaching Cushions to Mats, A. J. Strachan and C. B. Brown, London.
12,579. Rolling Mill Rolls, O. Klatte, London.
12,580. Manufacture of Metal Articles, O. Klatte, London.
12,581. Rolling Mill Rolls, O. Klatte, London.
12,582. Process for Producing Rolled Bars, O. Klatte, London.
12,583. Construction of Links for Chains, O. Klatte, London.
12,584. Starting Vehicles, P. D. Völker and H. Stammel, London.
12,585. Retaining Heat in Foods, S. M. B. von Szczawinski, London.
12,586. Shields for Resisting Shot, S. W. Yockney, London.
12,587. Tongue Rails of Switches, R. Price-Williams, London.
12,588. Hackling Machines, G. Lowry, London.
12,589. Holding Flax in Hackling Machines, G. Lowry, London.
12,590. Manufacture of Golf Balls, W. Hillman, London.
12,591. Brakes, W. Hillman and C. W. Wheeler, London.
12,592. Bookcases, G. H. Griffiths, London.
12,593. Ships' Winches, M. Colquitt, London.
12,594. Curtains, C. J. Curran, London.
12,595. White Lead, W. B. Priest, London.
12,596. Manufacture of Paper Tubes, A. J. Boult.—(*L. Grote, Germany.*)
12,597. Powders for Beverages, L. and H. G. Roberts, London.
12,598. Book-post Envelope, B. E. Straker, London.
12,599. Quick-firing Guns, G. F. Redfern.—(*E. Ternström, France.*)
12,600. Production of Selvedge on Piece-dyed Cloths, H. Baines, London.
12,601. Roundabouts, H. H. Lake.—(*The Firm of Christiansen and Meyer, Germany.*)
12,602. Casting of Metal Articles, H. H. Lake.—(*Van Riet*,———.)
12,603. Velocipedes, H. Vallée, London.
12,604. A Puzzle, N. Staniland, London.
12,605. Long Distance Telephones, W. A. Nikolajczuk, London.

*29th June*, 1894.

12,606. Producing Gas Oxide, W. E. Kenway.—(*B. C. Kenway, United States.*)
12,607. Floating Docks, L. E. Clark, Westminster.
12,608. Machinery for Type-setting, G. W. Hart, Nottingham.
12,609. Flooring Clamp, J. Hulton, Lancashire.
12 610. Operating Switch Point, H. Williams, Renfrewshire.
12,611. Looms, J. Entwistle and A. Earnshaw, Lancashire.
12,612. Toe-clip for Velocipede Pedals, H. Lucas, Birmingham.
12,613. Kilns for Burning Bricks, &c., H. T. Sully, Bristol.
12,614. Water-closets, A. Dyson, Huddersfield.
12,615. Recording Appliances, J. Shakespeare, Dudley.
12,616. Mangling Machines, H. C. Longsdon and F. Wilkinson, Keighley.
12,617. A New Boot System, The Countess C. Hugo, London.
12,618. Stands for Gongs, C. J. Adie and G. Evans, Birmingham.
12,619. Pneumatic Tires, I. Frankenburg and J. Tinto, Manchester.
12,620. Electric Arc Lamps, J. T. Niblett and M. Sutherland, London.
12,621. Colouring Matters, A. Ashworth and J. Bürger, Lancashire.
12,622. Bottle Washer and Rinser, F. O'Rorke, Dublin.
12,623. Mudguard for Bicycles, J. Anderson, Co. Down.
12,624. Picture Nails, S. Reeves, Birmingham.
12,625. Attaching Elastic Webbing to Trousers, H. Penn, Birmingham.
12,626. Winding Frames, J. Clayton and J. Stephenson, Burnley.
12,627. Safety Switch Signal Apparatus, H. McL. Abernethy and J. M. Graham, London.
12,628. Horticultural Buildings, T. Smithson, Bristol.
12,629. Gear of Winding Engines, J. G. Barclay, Glasgow.
12,630. Valves for Pneumatic Tires, J. Andrew, Glasgow.
12,631. Pneumatic Tires, J. Andrew, Glasgow.
12,632. Boots and Shoes, J. H. Sunderland, Glasgow.
12,633. Machinery for Cleaning Coal, W. Paton, sen., Glasgow.
12,634. Nitrates of Soda of Potash, &c , F. Hamer, Rugby.
12,635. Pickers for Looms, J. Muir and A. Muir, Glasgow.
12,636. Ventilators and Chimney Cans, A. Marshall, Glasgow.
12,637. Ore Roasters, J. E. L. Barnes.—(*A. G. Davis, United States.*)
12,638. Wheel Rims, W. Firth, Glasgow.
12,639. Stop Valve for Liquids, E Slack, Sheffield.
12,640. Watch Glass Substitute, H. Johnson and Co., Manchester.
12,641. Quote or Reversed Apostrophe, G. Terry, Stamford.
12,642. Tents, T. Moore, London.
12,643. Filtering, &c , Apparatus, N. G. Kimberley, London.
12,644. Attaching Caps to Wheels, J. Buffham and W. R. Harrison, London.
12,645. Attaching Springs of Vehicles to Axle Beds, W. R. Harrison and J. R. Porter, London.
12,646. Fish-hook Cases, S. Allcock and A. Stratton, Birmingham.
12,647. Securing Blinds to Rollers, W. Cook, Birmingham.
12,648. Stuffing-boxes, D. Spencer, U. M. Councill, and N. E. Woods, London.
12,649. Detonators, D. Hickie and G. F. Beutner, London.
12,650. Battery Plates, B. M. Drake and J. M. Gorham, Westminster.
12,651. Hinges or Supports for Gates, &c., A. Paillet, London.
12 652. Churns, &c , for Carrying Milk, T. H. Case, London.
12,653. Indicators, &c , for Lamps, G. H. Randall, London.
12,654. Advertising, A. C. Wright, London.
12,655. Conjuring Apparatus, W. P. M. Black, London.
12,656. Tube or Pipe Expander, A. Plenderleith, London.
12,657. Detachable Cup Handle, J. H. Weekes, London.
12,658. Manufacture of Neckties, F. J. Brown, London.
12,659. Thirst and Intoxication Indicator, G. Benevent, London.
12,660. Cycle Saddle Cantle-plates, A. Round, Birmingham.
12 661. Flexible Metallic Tubing, W. H. K. Bowley, London.
12,662. Projectiles for Rifles, &c., W. H. K. Bowley, London.
12,663. Purification of Gas, E. Hermite, C. F. Cooper, and E. J. Paterson, London.
12,664. Watch Dials, C. K. Colby, Wolverhampton.
12,665. Fastening Hats and Bonnets, E. Harvey, London.
12,666. Portable Colour-boxes, &c., T. H. J. Pryce, London.
12,667. Fireproof Building Construction, W. Clark, London.
12,668. Apparatus for Cutting Cloth, W. H. Maker, London.
12,669. Wash-basins, H. H. Lake.—(*W. Scott, United States.*)
12,670. Bath-tubs, H. H. Lake.—(*W. Scott, United States.*)
12,671. Scissors, E. Nowill, London.
12,672. Garter Clips, W. Rowbotham and M. Dickson, Manchester.
12,673. Folding and other Desks, J. E. H. Kunze, London.
12,674. Decreasing Draught of Vessels, W. and N. Pirrie, London.
12,675. Sulphuric Acids, A. Staub, London.
12,676. Holding and Displaying Eggs, J. J. Cousins, London.

*30th June*, 1894.

12,677. Sconce, H. Johnson, London.
12,678. Pickers for Looms, J. H. Webb, Ashton-under-Lyne.
12,679. Railway Signals, I. A. Timmis and G. N. Abernethy, London.
12,680. Non-slipping Pneumatic Tire, W. H. Hindle, Blackburn.
12,681. Air Pump Combined in Cycle Tube, J. Booth, Manchester.
12 682. Bicycle and other Tires, W. Gillespie, Nottingham.
12,683. Liquid Seal Gas and Air Valve, A. L. Rock, London.
12,684 Regenerative Gas Furnaces, A. L. Rock, London.
12,685. Camera Focussing Apparatus, E. M. M Smith, Spalding.
12,686. Cycle Tires, J. W. and J. W. Hancock, jun., Nottingham.
12,687. Labels, A. C. Vice, Nottingham.
12,688. Moulding Plastic Substances, H. Tempest, Keighley.
12,689. Driving Spinning Machines, J. Hargreavss, Keighley.
12,690. Preserving Articles of Food, H. Wilson, Preston.
12,691. Securing Locks of Safety Lamps, D. Evans, Merthyr Tydfil.
12,692. Golf Ball Holder, J. Davidson, Midlothian, N.B.
12,693. Gear for Driving Cycles, W. D. Cameron, Newry.
12,694. Steel and other Vermin Traps, W. Choat, jun., London.
12,695. Transposing Written Music, R. D. Barclay, Edinburgh.
12,696. Covers for Sanitary Vessels, W. T. Seymour, Stockton-on-Tees.
12,697. Rams for any Class of Ship, A. J. Budge, Sunderland.
12,698. Appliance for Use in Pork Pies, G. Wilkinson, Leicester.
12,699. Removing Sludge from Tanks, J. T. F. Bishop, Manchester.
12,700. Loom and Shuttle Guards, J. Grayson, Manchester.
12,701. Hammer and Screw-driver, J. A. Holt, Oldham.
12,702. Tobacco Pipes, R. H. Laing, Glasgow.
12,703. Raising and Forcing Liquids, J. Gilmour, Glasgow.
12,704. Indicating the Weight of Pulp, A. Johnston, Glasgow.
12,705. Address Tablet, A. Littlehales and H. Courtney, Birmingham.
12,706. Draught Preventer, A. and I. Buckley, Manchester.
12,707. Electric Lamp Holders, &c., J. B. Verity, Birmingham.
12,708. Utilising Bye-products, G. Dalton and T. B. Provis, Leeds.
12,709. Ferrules for Sticks and Umbrellas, E. Garlick, Sheffield.
12,710. Ingot Moulds, C. Oxley, Sheffield.
12,711. Organs, C. F. Brindley, Sheffield.
12,712. Transmitting Power, P. L. Renouf and F. Westwood, Birmingham.
12,713. Velocipedes, P. L. Renouf and F. Westwood, Birmingham.
12,714. Linen Fronts and Shirts, G. J. Gissing, London.
12,715. Water Gauges for Steam Boilers, G. Elliott, London.
12,716. Matches, E. G. Nott, Liverpool.
12,717. Tin Openers, T. Wignall and S. H. Thomason, Liverpool.
12,718. Time-checking Apparatus, J. T. Gent, A. W. Staveley, and I. H. Parsons, London.
12,719. Dovetailing Machines, J. Anderson, Newcastle-on-Tyne.
12,720. Curtain-rod Brackets, P. E. Ayton, Birmingham.
12,721. Terminals of Picture-rods, P. E. Ayton, Birmingham.
12,722. Bleaching Calico, Cloth, &c., C. H. Smith, Blackburn.
12,723. Economising Fuel in Grates, G. Shackleton, Bradford.
12,724. Water-closets, W. Bairstow, Bradford.
12,725. Balance Tricycle, E. F. Bellows, Leicester.
12,726. Sewing Machine Attachments, L. H. Smith, Glasgow.
12,727. Baby Chairs, W. McAuslan, Glasgow.
12,728. Wire Fencing, R. R. Main and R. Ramage, Glasgow.
12,729. Paper-making Machines, J. Craig and W Taylor, Manchester.
12,730. Power Transmitting Mechanism, A. E. and H. Robinson, Manchester.
12,731. Hat Attachment, W. A. Thornton, Leeds.
12,732. Billiard Table Cushions, W. H. B. Moorhead, Newry.
12,733. Boat Fall Detaching Gear, F. A. Rodewald, London.
12,734. Means for Propelling Boats, E. F. West, Birmingham.
12,735. Forcing Composition into Pipes, F. J. and A. R. Norman, Widnes.
12,736. Developing Photographic Plates, G. A. Barrett and D. M. Jones, London.
12,737. Cap Spinning, &c., Machinery, J. Pairstow, London.
12,738. Sliding and Swivelling Windows, W. Flitcroft, London.
12,739. Cottage Fire Ranges, J. Heywood, Manchester.
12,740. Billiard Table Cushions, J. E. Hopkinson, London.
12,741. Covers for Rubber Tires, J. E. Hopkinson, London.
12,742. Colouring Matters, H. E. Newton.—(*The Farbenfabriken vormals Friedrich Bayer and Co., Germany.*)
12,743. Hay-rakes, C. E. C. Townsend and T. Nunan, London.
12,744 Yachts, W. S. Winans, London.
12 745. Nails, A. Erdmann, London.
12,746. Receptacle for Cards and Scraps, P. Baumann, London.
12,747. Excluding Dust, R. C. Gardner.—(*M. Brown, Cape Colony.*)
12,748. Mounting Electric Lamps, W. Newbigging, London.
12,749. Belt or Rope Pulleys, &c., R. Combret, London.
12 750. Stand for Displaying Cards, H. C. Hall, London.
12,751. Hose Couplings for Railway Cars, C. Plettner and O. Lehmann, London.
12,752. Ball-bearings, N. de Gessler, London.
12,753. Flooring, &c , Cramps, J. and J. Hampton, London.
12,754. Lathes, J. Hampton, London.
12,755. Velocipedes, C. Chenet, London.
12,756. Tires, J. Morris, A. Clarke, and S. Andrews, London.
12,757. Scarves, W. Tremlett, London.
12,758. Ejecting Ashes from Ships, F. J. Trewent, London.
12,759. Feeding Bottle for Infants, E. K. Grenfell, London.
12,760. Varying Speed Motion, W. March, London.

*2nd July*, 1894.

12,761. Combustible Material, W. P. Thompson —(*E. Scott, United States.*)
12,762. Coloured Cloths, M. Kalisch, W. A. Rosenberg, and J. Entwisle, Manchester.
12,763. Safes, E. G. Wood and Milner's Safe Company, Ld., Liverpool.
12,764. Game Apparatus, T. Wignall and S. H. Thomason, Liverpool.
12,765. Photographic Exposure Meter, D. and W. S. Provand, Glasgow.
12,766. Carrying Cartridges, C. E. Stirling, Portsmouth.
12,767. Electric Incandescent Lamps, W. H. Willatt, Hull.
12,768. Barrel End, C. H. Matthews and E. Humphreys, Newtown.
12,769. Working Knitting Machines, T., J., and J. W. Kiddier, Nottingham.
12,770. Railway Signalling Apparatus, J. Atack, Blackburn.
12,771. Show Case, R S. and H. J. Vick, Bristol.
12,772. Washing Printers' Blanketing, W. Hadfield, J. J. Sumner, and H. Hadfield, Manchester.
12,773. Screw Propellers, J. W. Boyd, Glasgow.
12,774. Lock Furniture, W. Davies, Birmingham.
12,775. Game or Puzzle, C. W. and P. S. Faulkner, London.
12,776. Gas for Heating Purposes, T. Nicholson, Colwyn Bay.
12,777. Means for Advertising Purposes, J. Wilday Birmingham.
12,778. Churns, R. Wallwork, Manchester.
12,779. Ingredients for Feeding Horses, G. Thwaites, Stockton-on-Tees.
12,780. Locking Device for Cycles, E. Evans, Birmingham.
12,781. Vehicle for Distributing Liquid, D. McIntyre, Glasgow.
12,782. Soaps, W. M. Walters, Liverpool.
12,783. Tips for Furniture, A. U. Rinman, Manchester.
12,784. Separating Oil from Steam, J. G. Kincaid and W. Crockatt, Glasgow.
12,785. Spiral Cutters, H. Smith and J. Dickson, Sheffield.
12,786. Substitute for the Waistcoat, J. R. Churchill, Sheffield.

12,787. Rack for Window Curtain Rods, A. Sanderson, Sheffield.
12,788. Displaying Advertisements, A. R. Upward, London.
12,789. Method of Decorating Glass, J. T. Newell, London.
12,790. Boots and Shoes for Golf Purposes, G. Grant, London.
12,791. Driving Mechanism for Bicycles, R. W. Smith, Birmingham.
12,792. Shoes for Horses, J. Benfield, Birmingham.
12,793. Shoes for Horses, J. Benfield, Birmingham.
12,794. Shoes for Horses, J. Benfield, Birmingham.
12,795. Metal Plate for Furnaces, C. C. Mallett, London.
12,796. Cinchona Preparations, F. W. Fletcher, Middlesex.
12,797. Fixing Wheels to Axles, H. and C. E. Cowtar, London.
12,798. Tea Infusers for Cups, &c., H. W. Turner, London.
12,799. Automatic Cycle Supports, R. B. Chambers, Philadelphia.
12,800. Car Replacers, C. W. Archer, Philadelphia.
12,801. Motors, C. W. Johnston, Philadelphia.
12,802. Releasing Ships' Life Boats, J. Jennings, London.
12,803. Plastic Pipe-making Machinery, A. Noel, London.
12,804. Vermin Traps, J. Cable, London.
12,805. Dust Bin, J. Parsons, London.
12,806. Holding Flowers, A. L. Jones, London.
12,807. Safes, L. Mannstaedt, Barmen, Germany.
12,808. Augur, J. Swan, London.
12,809. Danger Switches for Signals, G. E. Edwards, London.
12,810. Nut Locks, F. Easom and D. W. Bassett, London.
12,811. Artificial Sandstone, J. Pfeiffer, London.
12,812. Tires, J. G. A. Kitchen, London.
12,813. Lemon Squeezer, R. D. Crockford, London.
12,814. Couplings for Railway Vehicles, J. W. Parker, London.
12,815. Furnaces, G. R. Steward, London.
12,816. Marine Engine Telegraphs, B. G. Hjärne, London.
12,817. Incandescent Lamps, A. Zobel and F. Buchmüller, London.
12,818. Manufacture of Glove Leather, L. Cohn, London.
12,819. Propelling Locomotive Torpedoes, H. H. Doty, London.

*3rd July*, 1894.

12,820. Mixing Explosive Gases, A. H. Tyler and J. S. E. de Vesian, London.
12,821. Manufacture of Paper Wires, G. Tankard, Leeds.
12,822. Automatic Advertising Device, S. Bunting, Birmingham.
12,823. Manufacture of Ladder Tapes, T. French, Manchester.
12,824. Constructing Cycle Wheel Hubs, J. W. Bayliss, Coventry.
12,825. Coat Fastener, H. S. Gent, Birmingham.
12,826. Knitting Machines, R. Wallwork, Manchester.
12,827. Mudguards, J. Mullineux, London.
12,828. Thimble, M. Tibbitts, London.
12,829. Removing Cotton Fibre, W. Lord and F. Woodhead, Manchester.
12,830. Wheel for Cycles and Vehicles, J. Buchanan, London.
12,831. Cases for Cotton Silk, T. Morton, Birmingham.
12,832. Coupling for Rods, H. Stone and F. D. Tippetts, Birmingham.
12,833. Perambulator, &c., G. Moore, jun, Birmingham.
12,834. Brick-making Machines, T. C. Fawcett, Halifax.
12,835. Corsets, F. Manks, Halifax.
12,836. Extracting Fat from Wool, C. N. Wilson, Bradford.
12,837. Fixing Sash Windows, H. A. Holmes, Harrogate.
12,838. Slate and Tile Fastener, W. Lynch, Sheffield.
12,839. Administering Medicine to Infants, J. McCullagh, Dublin.
12,840. Cooling Water in Engines, S. H. Terry, London.
12,841. Projecting Flanges, H. T. Clarke and R. Brown, Sunderland.
12,842. Lubricators, D. D. Brown, Glasgow.
12,843. Hay Turners, M. T. Hill, Birmingham.
12,844. Frame for Containing Type Cases, W. Smith, Glasgow.
12,845. Textile Fabrics, T., J., and J. W Kiddier, Nottingham.
12,846. Tube Fastenings for Boilers, J. Haythorn, Glasgow.
12,847. Measuring Apparatus for Liquids, R. Pickwell, Cardiff.
12,848. Window Sashes, &c, T. and J. C. Jones, Aberavon.
12,849. Rope Haulage, T. Heppell, J. Wright, and A. P. Stoker, Barnsley.
13,850. Building Water-tight Tunnels, J. E. Humphris, Oxon.
12,851. Steam Hammers, Carron Company and A. Robertson, Glasgow.
12,852. Wool-carding Machines, F. A. Graul, Glasgow.
12,853. A New and Original Board Game, K. Le Lean, Plymouth.
12,854. Ticket Holder, E. Bornheim and E. Stabenow, Glasgow.
12,855. Kiln for Baking China, J. Sherwin, Manchester.
12,856. Producing Printing Surfaces, A. T. Winkel, London.
12,857. Machine Guns, J. M. and M. S. Browning, London.
12,858. Pulleys of Lifts, Otis Elevator Company, Ld.—(*Otis Brothers and Co., United States*.)
12,859. Paper-making Machinery, E. E. Rawson, London.
12,860. Pipes, H. Brooks, London.
12,861. Fishing Apparatus, E. Poppowitsch and H. Wüstenfield, London.
12,862. Ankle-supporting Boots, J. M. Horn and M. Mayer, London.
12,863. Rotary Action for Machinery, F. E. Hollyer, Brentford.
12,864. Medical Syringes, A. J. Boult.—(*J. Rosenberg, Germany*.)
12,865. Clamping the Ends of Ropes, W. P. Thompson.—(*J. Allenson and A. Adams, United States*.)
12,866. Stocking Dyeing Apparatus, M. Cockcroft, London.
12 867. Telephone Cabinets, T. Weighill and G. Moore, Liverpool.
12,868. Pins for Hats, H. Martin and J. S. Miller, London.
12 869. Furnaces, W. P. Thompson.—(*F. Jimenez-Ulibarri, Spain*.)
12,870. Electric Switches, C. Hamilton, Glasgow.
12,871. Tobacco Pipes, C. Wellin, London.
12,872. Rust Preventive Compositions, F. Evers, London.
12,873. Confection Preparing Machine, J. Ritchie, Glasgow.
12,874. Lock Gates, A. D. F. de Villepigue, London.
12,875. Alternating Current Meter, J. F. Kelly and W. Stanley, London.
12,876. Crimping Machines, H. H. Lake.—(*E. P. Holden, United States*.)
12,877. Controlling Machinery, H. H. Lake.—(*J. D. Williamson, jun., United States*.)
12,878. Woven Fabrics, &c., W. G. Connell and J. H. Lorimer, London.
12 879. Renewing Old Steel Rails, E. W. McKenna, London.
12,880. Cooling or Condensing Fluids, G. Barnard, London.
12,881. Obtaining Ammonia Salts, H. H. Lake.—(*L. Sternberg, United States*.)
12,882. Roundabouts, J. Armitage, A. Herschell, and G. C. Herschell, London.
12,883. Metal Cans, H. H. Lake.—(*E. and O. W. Norton, United States*.)
12,884. Metal Cans, H. H. Lake.—(*E. and O. W. Norton, United States*.)
12 885. Soldering Metal Cans, H. H. Lake.—(*E. and O W. Norton, United States*.)
12,886. Testing Metal Cans, H. H. Lake.—(*E. and O. W. Norton, United States*.)
12,887. Pipe-stem Clearers, J. S. Beeman, London.
12,888. Smokeless Combustion, J. C. Fell.—(*M. M. Armstrong, United States*.)
12,889. Raising Sunken Vessels, &c., A. S. Harrison, London.
12,890. Signalling, W. K. Partington and A. W. Brown, London.
12,891. Fastening for Driving Belts, T. F. Edwards, London.
12,892. Pneumatic Impact Tools, J. F. Clement, London.
12,893. Destroying Garbage, H. E. Newton.—(*The Pinhoe Patent Refuse Destructor Company, Australia*.)
12,894. Channelling Machines, P. A. Newton.—(*The Ingersoll-Sergeant Drill Company, United States*.)
12,895. Liquid Dispensing Apparatus, W. M. Fowler, London.
12,896. Wrapping Newspapers, H. E. Newton.—(*R. Hoe, United States*.)
12,897. Wirework for Cages and Traps, A. M. Morin, London.
12,898. Shirt Cuff Tablet for Notes, &c., T. Coad, London.
12,899. Device for Securing Buttons, J. Tidmarsh, London.
12,900. Apparatus for Obtaining Power, C. Hume, London.
12,901. Stop Motions, C. R. Makepeace and W. Haines, London.
12,902. Cooking Stoves, &c., W. W. and J. England, London.
12,903. Purifying Air, &c., Count H. von Pückler, London.
12 904. Vapour Burning Apparatus, S. Holmes, London.
12,905. Roofing Tiles, C. W. Knox, London.
12,906. Umbrellas, A. H. White, London.
12,907. Pin Fastenings for Ladies' Hats, S. E. Mercer, London.
12,908. Bobbin and Attachment, G. M. Armitage, London.
12,909. Tinder Box, L. Korchikov and M. Machschefcs, London.
12,910. Coin-freed Apparatus, &c., G. Hirschfeld, London.
12,911. Glue-making Machinery, P. C. Hewitt, London.
12,912. Gauge Glass Sight Indicator, R. H. Goldie, London.
12 913. Cycle Rest, F. L. Chambers, E. I. Watson and H. R. Everitt, London.
12,914. Colouring Leather, R. Haddan.—(*A. Avellis, Germany*.)
12,915. Ventilating Railway Tunnels, E. Weidlich, London.
12,916. Separation of Minerals, &c., W. Scott, London.
12,917. Reversing Gear for Motors, A. J. Boult.—(*K. Lausmann, Russia*.)
12,918. Cleat, C. N. Curtis, London.
12,919. Boring and Tunnelling Earth, J. S. Williams, London.

*4th July*, 1894.

12,920. Knives for Cutting Boot Soles, G. T. Phillips, Northampton.
12 921. Carrying Prints in Penholders, J. Otway, Waterford.
12,922. Mechanical Toys, J. W. May and W. Taylor, Gainsborough.
12,923. Tent and Marquee Fastener, A. B. Wilkinson, Ashton-under-Lyne.
12,924. Blind Roller Furniture, W. T. Robertshaw, Manchester.
12,925. Steam Generators, J. Blake, Manchester.
12,926. Feeders for Scutchers, E. Tilston, Manchester.
12 927. Safety Valves for Ranges, &c., J. Kitchen, Derby.
12,928. Commutator Brushes, &c., J. A. Edmondson, Leeds.
12,929. Crushing Ores, D. Embleton and G. Glossop, Leeds.
12,930. Windows, S., J., and J. D. Fletcher, Glasgow.
12,931. Shelves for Shop Windows, J. Macfarlane, Glasgow.
12,932. Indicating Positions of Trains, C. J. Francis, Glasgow.
12,933. Protector for Umbrella Covers, L. Turnick, Stockport.
12,934. Miners' Picks, W. Seedhouse, R. Norbury, and C. E. Trickett, Sheffield.
12,935. Carding Engines, J G. Bamforth and W. H. Bamforth, jun., Huddersfield.
12,936. Packing Fluid-tight Joints, G. E. Adams, London.
12,937. Looms, B. Kay, Halifax.
12,938. Looms, J. H. Bryant, Stonehouse.
12 939. Clips or Bosses for Cycle Saddles, R. Mason, Birmingham.
12,940. Hat-boxes, H. and A. H. Stevenson, Manchester.
12 941. Velocipedes, P. L. Renouf and F. Westwood, Birmingham.
12,942. Luggage Carriers for Cycles, W. L. J. Orton, Leicester.
12,943. Keys, W. W. Hare, London.
12,944. Copper Hot-water Cylinders, J. Radford, Bradford.
12,945. Measuring Apparatus, M. Lydon, North Shields.
12,946. Arc Lamps, S. Sealy-Allin and W. H. Wood, London.
12,947. Attaching Door Knobs, J. J. Sumner, Birmingham.
12,948. Cycle Saddles J. B. Brooks, Birmingham.
12,949. School Drawing Compasses, A. A. Woodward, Birmingham.

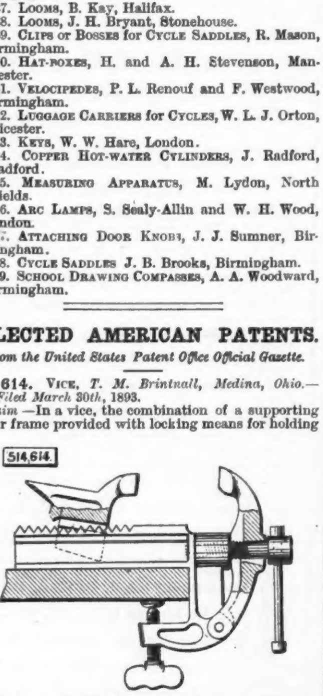
## SELECTED AMERICAN PATENTS.

***From the United States Patent Office Official Gazette.***

**514 614.** Vice, *T. M. Brintnall, Medina, Ohio.—Filed March 30th*, 1893.

*Claim.*—In a vice, the combination of a supporting bar or frame provided with locking means for holding the rear jaw of the vice and having longitudinal flanges or shoulders, a rear jaw having grooves which engage the flanges of the frame and adapted to be slid longitudinally on said frame, a front jaw pivoted at its lower end to the frame, and an adjusting screw which passes through the front jaw and enters the head of the frame for adjusting the upper end of said jaw, substantially as described.

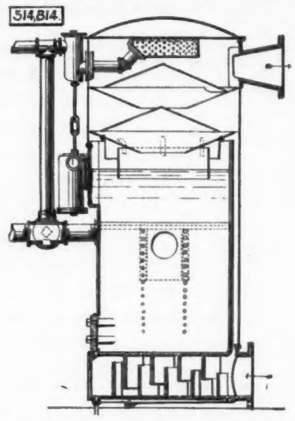
514,614.



**514,814.** Feed-water Heater and Purifier, *J. G. Cooper, Cincinnati, Ohio.—Filed March 30th*, 1893.

*Claim.*—(1) In a feed-water heater and purifier, the combination of a cylindrical base section having a steam inlet, a settling chamber of less diameter than said base section and supported thereon, means for supplying water to the settling chamber, an outer shell or jacket surrounding the settling chamber or inner shell and forming an annular unobstructed heating chamber or space that communicates with the cylindrical base section below and with the settling chamber above, and alternating plates located in the base section and constituting an oil extractor, whereby steam admitted to the base section will traverse a horizontally tortuous course over the plates of the oil extractor and ascend in whirling currents through the heating chamber and enter the top of the settling chamber, substantially as described. (2) In a feed-water heater and purifier, the combination of an inner open top shell enclosing a settling chamber and a filtering chamber which communicate at or near the top, an outer shell or jacket forming a heating chamber around the inner shell and extended above the same, a water inlet pipe leading into the upper part of said outer shell, a valve casing communicating with said pipe and enclosing a valve to automatically control the supply of water, a trapped overflow chamber communicating with the upper part of the settling chamber and enclosing a float chamber, a float placed in said chamber and attached to the rod or stem of the water supply valve, a pipe leading from the filtering chamber and provided with a three-way valve, and a pipe connecting said three-way valve with the water supply pipe, substantially as described.

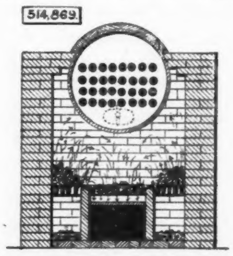
514,814.



**514,869.** Smokeless Boiler, *W. S. Plummer, St. Louis, Mo.—Filed August 9th*, 1893.

*Claim.*—A smoke-consuming furnace having a single down-draught grate, and up draught grates located on opposite sides of said down-draught grate, substantially as herein specified.

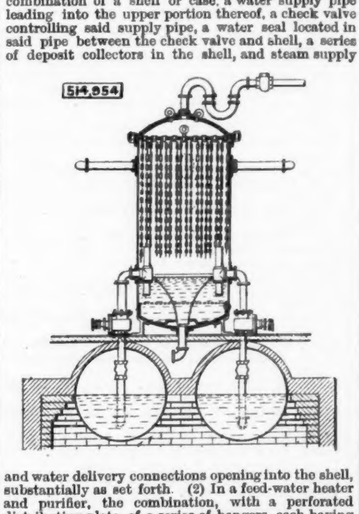
514,869.



**514,954.** Feed-water Heater and Purifier, *R. G. McAuley, Pittsburg, Pa.—Filed June 3rd*, 1893.

*Claim.*—(1) In a feed-water heater and purifier, the combination of a shell or case, a water supply pipe leading into the upper portion thereof, a check valve controlling said supply pipe, a water seal located in said pipe between the check valve and shell, a series of deposit collectors in the shell, and steam supply and water delivery connections opening into the shell, substantially as set forth. (2) In a feed-water heater and purifier, the combination, with a perforated distributing plate, of a series of hangers, each having a centrally perforated hub or boss and a series of peripheral hooks or arms, and connecting bolts passing through the central openings of the hangers and through the distributing plate, substantially as set forth.

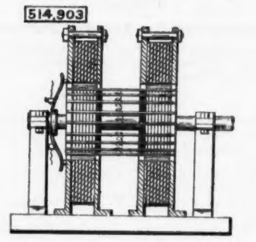
514,954.



**514,903.** Alternating Current Electric Motor, *C. S. Bradley, Avon, N.Y.—Filed September 27th*, 1892.

*Claim.*—(1) An alternating current motor having one element wound to develope progressively-shifting magnetic poles, and the other element provided with a closed secondary circuit inductively related to the shifting poles, means for developing opposing electro-motive forces in the secondary circuit and a common path of relatively high resistance forming a multiple arc circuit for currents due to the opposed electro-motive forces. An alternating current motor having one element wound to develope progressively-shifting poles and the other element provided with a closed secondary circuit of low resistance inductively related to the shifting poles, and means for developing when desired opposing electro-motive forces in the secondary circuit, said circuit being provided with a high resistance shunt forming a multiple arc circuit for currents due to the opposed electro-motive forces.

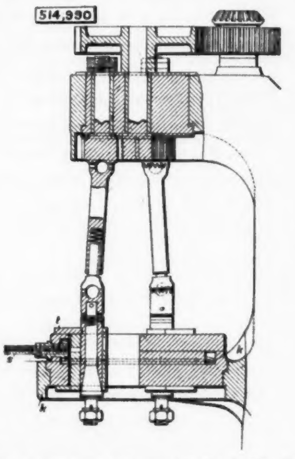
514,903.



**514,990.** Metal Drilling Machine, *W. Habersang and F. Zinzen, Dusseldorf, Germany.—Filed December 11th*, 1891.

*Claim.*—The combination of jointed boring shafts having ball-bearings, with tool holders secured to the shafts, sliding bearings engaging the tool holders, a disc engaging the sliding bearings and with cog-wheels *t*, gear-wheel *k*, and screws *s* operated by the wheels *t* and *k*, substantially as specified.

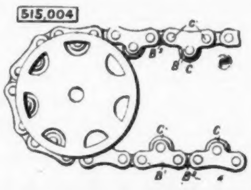
514,990.



**515,004.** Drive-chain, *L. W. Loomis, Carrollton, Ill.—Filed May 19th*, 1893.

*Claim.*—The herein-described drive-chain, consisting of the links B′ each having side pieces or cheeks *c c*, pivot studs *c′* connecting said cheeks at each end of the same and intermediate the said ends, anti-friction rollers C mounted on the intermediate studs *c′* and projecting beyond one of the lateral edges of the said links B′, and links $B^2$ connecting the links B′ and pivotally mounted at their ends upon the adjacent pivot studs of adjoining links B′, said links lying between the cheeks *c*, of the said links B′, all arranged as and for the purpose specified.

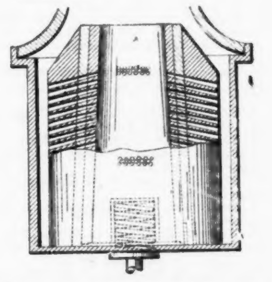
515,004.



**515,053.** Centrifugal Creamer, *F. O. Nilsson, Stockholm, Sweden.—Filed September 28th*, 1891.

*Claim.*—(1) In a centrifugal separator, the combination of a rotary drum, a hollow cylinder therein with a space between it and the drum, said cylinder having inclined openings extending through its walls, substantially as described. (2) A centrifugal separator comprising the rotary drum and the cylinder made up of a series of conical sections having perforations therein, adapted to register, substantially as described.

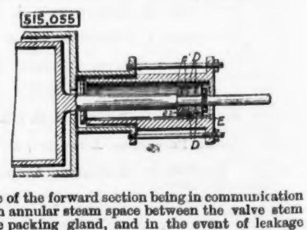
515,053.



**515,055.** Valve Stem Packing, *J. Olson, Two Harbours, Minn.—Filed August 11th*, 1893.

*Claim.*—A spider E carrying packing rings D formed of a rabbeted ring sections E forming spaced packing seats and each having an oblique peripheral steam inlet $e^2$ leading into its rabbet seat below the packing ring, said sections being arranged between a shoulder and an adjusting nut on a valve stem, the steam inlet passage of the forward section being in communication with an annular steam space between the valve stem and the packing gland, and in the event of leakage behind the first packing ring the steam inlet to the channel seat of the second packing ring will also be in communication with said annular steam space, and so on according to the number of rings employed, substantially as decribed.

515,055.



## THE COMPETITION OF SELF-MOVING ROAD VEHICLES IN FRANCE.

(*By our Special Commissioner.*)

THE great increase in the public interest shown in all kinds of outdoor exercises is one of the most striking features observable in French national life within recent years. The visitor to Paris or to any other large town will now see as many cycles as in a similar town in England; he will be struck by the number of ladies who are cyclists, and probably surprised to see the greater proportion of them wearing loose Turkish trousers. Upon the Seine and the Marne he will observe pleasure boats almost as numerous as those on the Thames itself, and these boats are let on hire at very low rates; there are many well-known rowing clubs, and it will be fresh in the memory of most of our readers that an English crew was beaten on the Seine by a French crew. There is no doubt a very strong public spirit, the growth of a few years, which has entered in a most enthusiastic manner into the project of attracting the youth of France from the cafés and other lounging-places of the gay city and encouraging the young people of both sexes to take amusement in the open air.

One of the most potent factors in the creation of this public spirit has been the widely disseminated and, we believe, well-grounded belief that the population of France, if not actually diminishing in number, is at least not increasing at all. In view of the rapid and well sustained increase in numbers of the Germans and other neighbouring populations, this fact is considered worthy of grave consideration, and many of the best men in France are endeavouring to find a solution of the difficulty.

Speaking generally, the youth of France appears to have enthusiastically responded to the invitation to take more exercise in the open air. If football and cricket do not appear so far to have found great favour here, there are many other forms of sport which are well patronised. The proprietors of *Le Petit Journal*, a well-known Parisian paper having, I believe, by far the widest circulation of any French newspaper, have for some years made special efforts to encourage out-door exercises. One of the chief members of the staff of the journal, who is known as "Jean-sans-terre," has been specially occupied with this particular class of work, and the numerous articles which have appeared from time to time are all signed by him.

In the year 1891 a competition of cyclists was arranged by *Le Petit Journal*, and the course was from Paris to Brest and back. This was extremely successful, and immensely increased the interest taken in cycling, and the result has been very gratifying, as the use of the cycle has so largely increased that there is no further need of encouraging it. In 1892 a walking match was instituted between Paris and Belfort, which also had very successful results; and it was a matter of some surprise that, in 1893, no public competition of importance was arranged by the newspaper. There was indeed a competition for the best dog muzzle; but that was of quite minor interest. The reason for the absence of enterprise last year is explained by the fact that it was quite uncertain at what date the elections would take place. It was hoped that a swimming competition might be got up, as it was thought that this branch of athletics has been too much neglected in France; but the fear of one or more cases of drowning occurring during these contests in the Seine or the Marne, has so far kept the journal from undertaking this branch of sport.

This year, however, it was decided that an attempt should be made to encourage the construction of road vehicles which should be actuated by some kind of motor. It was thought that if the use of horses was unnecessary, it would become possible for a family to go out and enjoy a drive in their own vehicle at small expense, and that more use would thus be made of the splendid roads of France, so much praised by all cyclists, whether of native or foreign origin. The construction of such vehicles has made such small progress in Great Britain, and the demand for them appears to be so trifling, that I have been much interested in following the announcements which have from time to time appeared in *Le Petit Journal*. It is well said in the journal that the cycle is all very well for young and vigorous members of a family, but that there is still great scope for inventors to assist the remainder of the family to enjoy themselves economically.

In December of last year the subject was first broached, and it was explained that there would be no question of racing along the high roads, but the object would be to find which vehicles best fulfilled the known requirements of the public. The trials were then fixed for the beginning of June, 1894. The regulations were few in number, and shortly as follows. The competition would be open to all comers, and any kind of motor would be allowed; the vehicles would be judged by a jury consisting of the staff of *Le Petit Journal*, assisted merely in their consultative capacity by consulting engineers. Each vehicle was to be capable of carrying at least four persons, but no restriction was put upon the seating capacity.

Security, easy management, and cheapness were the essential features desired. Each vehicle was to be submitted first of all to a preliminary run, in which it was to cover thirty-one miles in four hours—a speed of 7¾ miles per hour being considered quite sufficient for ordinary use. No notice would be taken of a speed exceeding the stipulated rate. Each carriage was to carry the inventor or builder, one or two members of the jury, and a consulting engineer, and marks were to be given up to 20. No vehicle would take part in the final test which had not obtained 16, 17, 18, 19, or 20 marks in the first run. No note would be taken of costly upholstery or mere superfluous finish; it was desired above all to find a thoroughly good design of vehicle. Entries were received from December 29th, 1893, each entry costing 8s. 4d. All the profits were to go to the Charity Fund of the paper.

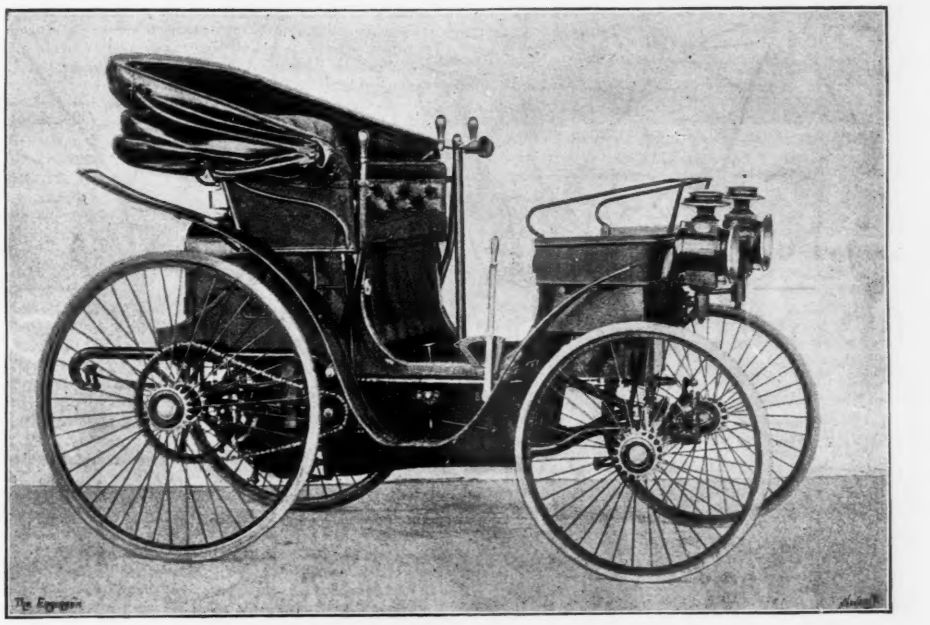


Fig. 3 DAIMLER VICTORIA

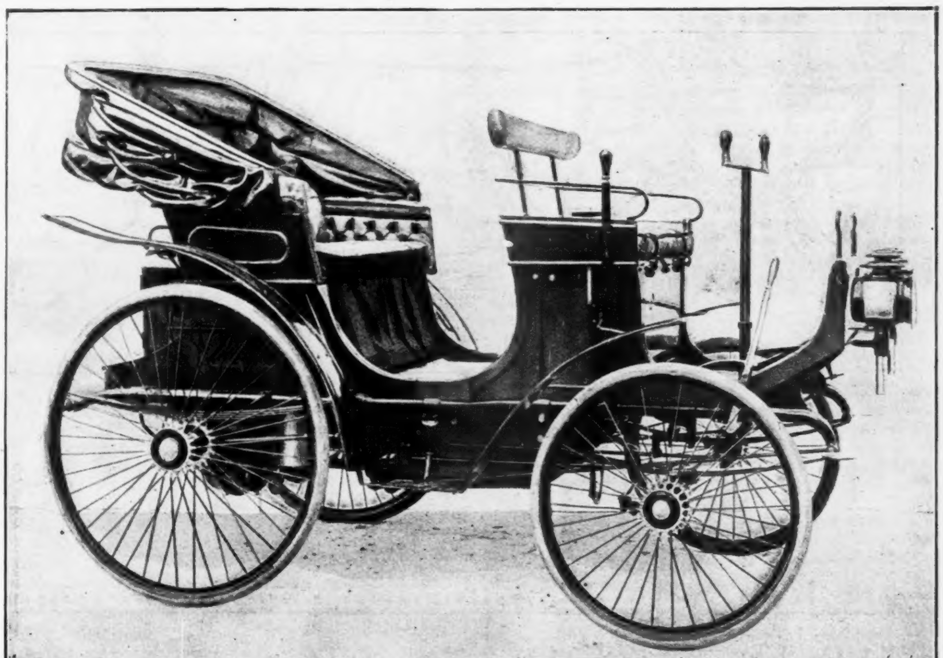

Fig. 4—DAIMLER PHÆTON

The first prize is of the value of £200, and is known by the name of the journal; the others are as follows: second prize, £80; third prize, £60; fourth prize, £40; fifth prize, £20. These latter are known as the Prix Marinoni, and are due to the personal liberality of Mr. Marinoni, one of the proprietors of the paper, who is himself a clever mechanic and inventor. Some persons objected to a jury consisting of journalists, and considered that it would have been preferable to have had the relative merits of the vehicles judged by experts; but the proprietors consider that their staff will well represent public opinion, and will be prevented from being carried away by a too loquacious inventor owing to the assistance derived from the consulting engineers. It was pointed out by some inventors that it would be better not to require each vehicle to carry at least four persons, and a change was therefore made in the rules by which any vehicle was admissible which could carry at least two persons, but that a vehicle carrying less than four people would not be eligible for the first prize, and that only two prizes out of the five would in any case be given to such a vehicle. It may be well to remark that by a police regulation dated 14th August, 1893, no self-moving vehicle is permitted to travel along the public roads in towns at a speed exceeding 7·44 miles per hour—12 kiloms.—nor at a speed exceeding 12·4 miles per hour—20 kiloms.—in the open country. This regulation is applicable to the whole of the department of the Seine.

The competition is especially organised to encourage inventors, and therefore the prizes will not be given to the mere possessor of a vehicle unless he shall have made some radical improvement in its mechanism, sufficient in the opinion of the jury to constitute it a distinct type. Having now explained as briefly as possible the origin of the competition, and put your readers in a position to understand the importance of the trials, I will proceed to examine the results obtained in the form of entries. No entry was admissible after April 30th, 1894, the lists having then been open over four months.

So great an interest has been taken in the matter by the public that a pamphlet has been published by *Le Petit Journal*, in which the various articles which have from time to time appeared in the paper are reprinted with the rules and also maps of the route and descriptive matter. These were sold by the thousand at 2d. each, and the profits are to be added to the charitable fund of the paper. There are 102 entries altogether from 93 different persons or firms, and I am surprised to find only one entry from a person in the United Kingdom. There are only two entries from Germany, and I think British engineers will be somewhat surprised to learn that France should be able to produce so many types of self-moving road vehicles.

It was found that some of these carriages could not be ready for competition by June 1st, so a ballot was taken for postponing the date, and this resulted in obtaining an overwhelming majority for a later date. Finally it was arranged that Thursday, Friday, and Saturday, the 19th, 20th, and 21st July should be reserved for the preliminary trials, and that the final trial should take place on Sunday, July 22nd. As it would never do to have a large number of vehicles running in a confused mass upon a public highway, six different routes were chosen for the preliminary tests, and these are shown upon the map, Fig. 1. Each vehicle will start from the restaurant Gillet, at Neuilly, just outside the Porte-Maillot, Paris. The routes will be as follows:—

(1) Paris to Mantes, 29 14 miles.
(2) Paris to Mantes, 31·62 miles.
(3) Paris to Magny-en-Vexin, 32·24 miles.
(4) Paris to Rambouillet, 31 miles.
(5) Paris to Corbeil, 34·72 miles.
(6) Paris to Précy-sur-Oise, 32·24 miles.

Your readers will be able easily to trace upon the map the different routes, and to note the names of the towns and villages through which the vehicles will pass.

EXPLANATION

*The names of the Towns on the six routes are printed in heavy type; those at the termini are underlined. The six routes are shown in heavy lines.*

*The starting point is at the Gillet Restaurant, Gillet, and all the carriages will pass along the Avenue de Neuilly.*

*Route 3 follows Route 2 up to Croix de Noallies. Routes 4 & 5 are the same up to the Place d'Armes, Versailles.*

ROUTE OF THE PRELIMINARY TESTS.

"The Engineer" Scale 0 1 2 3 4 5 6 7 8 9 10 Kilometres

Swain Eng.

Each carriage must be provided with four number plates, and these are to be of enamelled iron with figures in white on a blue ground, so that the public by referring to the pamphlet—of which I have just spoken—will be able to know the name of the maker or inventor. The final trial will take place from Paris to Rouen, a distance of 79·36 miles, on Sunday next. This appears to me to be a very sufficient test of any vehicle, and should prove whether the design and manufacture of the apparatus are suitable for the purposes required. A map of this last route is given in Fig. 2; and it will be noted that, in both Figs. 1 and 2 the sections of the roads are given, so that really valuable data will be obtainable. As I have—by the kindness of Mr. Jean-sans-terre—received a special invitation to ride in one of the carriages, I shall, I hope, be able to give you detailed information as to the class of road, wind, and weather, as well as refer to the designs of the various vehicles.

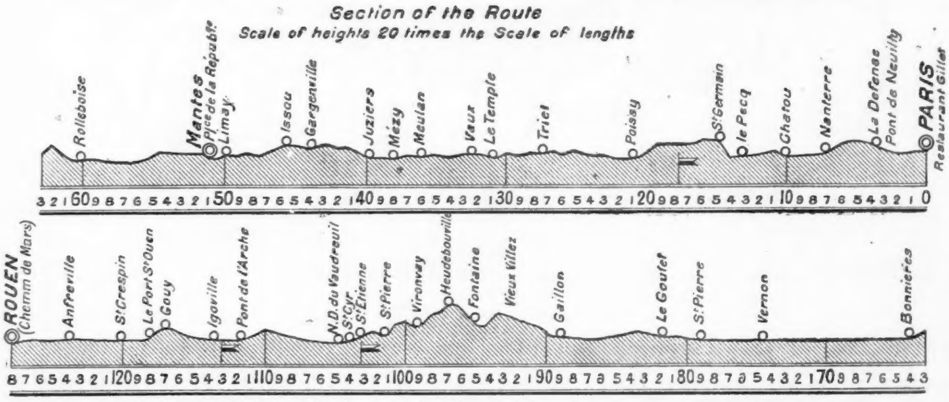
ROUTE



Plan and Section of the Route for the Final Test from Paris to Rouen, 128 kilometres.

By Article 29 of the police regulations, it is forbidden to use a motor car to draw any other vehicle, so that each vehicle must be self-contained. The time is now close at hand when the trials will come off, and in order to give the public every opportunity of examining the vehicles, they were on view in the Neuilly Park on Wednesday, from 2 p.m. to 6 p.m. The Mayor of Neuilly, General Henrion-Bertier, has made the arrangements for this public view, when the motors will not be shown at work, this being merely a preliminary general view. On Tuesday lots were drawn by the competitors, to determine which of the routes each vehicle is to follow.

As was foreseen by the proprietors of *Le Petit Journal*, a number of the competitors are not ready even now, although six weeks more than was originally intended have been allowed, and I learn after consulting Mr. Jean-sans-terre, that, roughly speaking, about fifty vehicles out of the 102 entered will take part in the trials. This is considered a very satisfactory result, and should lead to a good competition. I find that the only English vehicle entered will not appear. As there are fewer competitors it has been decided not to use route No. 3 at all. This was from Paris to Magny-en-Vexin, and was decidedly the worst of the six routes; and from Pontoise to Magny it was paved in the manner customary in the reign of Louis XIV. Besides this there will be no need to run any trials on Saturday next, so far as can be seen at present, although the weather has been so wet lately that fine days cannot be counted upon. M. Michel Levy, of 26, Rue Spontini, a mining engineer, has been specially appointed by the Prefect of Police to examine the vehicles before they are allowed to run upon the public roads, and he will be assisted by M. Bocher, also a mining engineer.

As it will not be definitely known for a couple of days exactly which vehicles will take part in the contest, I have been unable to obtain all the technical information I desired; but as one firm has entered six separate vehicles, I consider this a proof that the designs have been thoroughly worked out by them, and I am able to illustrate some of the carriages. This firm is Messrs. Les Fils de Pengest Frères, of Valentigney (Doubs), who also have a depôt at 22, Avenue de la Grande-Armée in Paris. The whole of these various types of vehicles are fitted with the Daimler-Gazoline motor—which, I may remark in passing, has been recently introduced into England, and is being fitted into several launches now being built on the Thames. These motors are built by Messrs. Panhard et Levassor, 19, Avenue d'Ivry, Paris, and are of the two-cylinder type. The power of the motor is sufficient to produce a speed of 2·5 to 3·1 miles per hour on inclines of 1 in 12 to 1 in 10, and a speed of 9·3 to 11·2 miles on the level when the road is good and dry, the vehicle being fully loaded with the number of passengers it is designed for, allowing a weight of 165 lb. per passenger. The vehicle can be run at two different speeds, and the gear for changing the speed is easily worked while travelling. In cases where the district is very level, a higher speed can be arranged for if permissible by the police regulations.

Fig. 3 illustrates a Victoria for four persons. The extreme length is 8·86ft.; width, 4·85ft.; gauge, 4·26ft. The wheels are of the cycle type, with pneumatic tires, and it will be seen that the controlling lever is in front. The motor drives on the hind axle. The framework consists of cold drawn weldless steel tubes, joined by wrought or cast steel parts. It serves as a reservoir for the cold water used for cooling the cylinders. The spokes of the wheels are of steel, and so made that they can be replaced in case of accident, while the wheel remains in its normal position. The price of this carriage fitted throughout as shown in Fig. 3 is £268 in Paris.

Fig. 4 represents a second type made by the same firm, which is quoted at £248. The length is 8·4ft.; width, 4·6ft.; gauge, 3·94ft. I have been unable as yet to obtain the weights of these vehicles, but they well represent the work turned out by this firm, who are very well known as cycle manufacturers. All the six vehicles entered for the competition are of different types. The prices, it will be seen, are somewhat beyond the purses of the classes for which *Le Petit Journal* has specially interested itself; but it must be remembered that there is as yet a very small demand for this class of vehicle, and the enterprise of this particular firm is very considerable. The Department of Doubs borders Switzerland, and is therefore a considerable distance from Paris. Still, notwithstanding this, the firm invite intending buyers to go there for instruction in the handling of the motors and guidance of the vehicles.

I have stated that out of the 102 carriages which were originally entered for the competition, I expected about fifty would take part, the rest being for various reasons unable to appear.

I am now able to give a complete list of the "probable starters," which are as follows. The numbers at the left being those quoted in the official list of entries.

3.—Messrs. Dion Bouton et Cie., 12, Rue Ernest Puteaux (Seine). Brake, to seat six. Actuated by steam.

4.—*Idem* Victoria bogie carriage to seat four. Steam.

7.—P. Gautier, 59, Boulevard Arago, Paris; to seat four. Petroleum motor.

10.—J. Scotte, Epernay (Marne), to seat eight to ten. Steam.

12.—Tenting, 46, Rue Curial, Paris, to seat four. Petroleum.

13.—Panhard et Levassor, 19, Avenue d'Ivry, Paris; ordinary type, to seat four. Daimler motor.

14.—*Idem* new type, to seat four.

15.—*Idem* to seat two.

16.—Quantin, 27, Rue St. Amand, Anzin (Nord), to seat six. Petroleum.

18.—Ernest Archdeacon, 121, Avenue de Wagram, Paris, to seat six or seven. Serpollet steam motor.

19.—A. Le Blant, 19, Rue Geoffroy-Saint-Hilaire, Paris, to seat eight or ten. Steam. Built by Messrs. Chastel and David.

21.—Alex. Letar, 58bis, Rue Sainte Anne, Paris, dog cart to seat four. Steam.

24.—Alfred Vacheron, Forges de Phade, near Monthermé (Ardennes), to seat two. Gasoline.

25.—Coquatrix, 74, Boulevard Voltaire, Paris, to seat four. Steam.

27.—Les Fils de Peugeot Frères, Valentigney (Doubs), to seat two. Daimler motor.

28.—*Idem* to seat four *vis-à-vis*.

29.—*Idem* to seat four. Victoria.

30.—*Idem* to seat three. Open cab.

31.—*Idem* brake to seat five.

37.—A. Loubière, Ferté-sous-Jouarre (Seine et Marne), to seat six. Levers.

40.—L. Lemoigne, Fougères (Ille-et-Vilaine), to seat four. Weight of passengers.

42.—A. le Brun, 10, Rue Alsace-Lorraine, Rouen (Seine Inferiure), to seat four. Petroleum.

44.—De Prandières, 31, Place Bellecour, Lyons, to seat six. Serpollet type and petroleum combined.

51.—Lepape, 23, Rue Montaigne, Paris, to seat four. Petroleum.

52.—La Société Parisienne de Constructions Velocipediques, 10, Avenue de la Grande Armée, Paris, to seat four. Compressed air at constant pressure. Durand type.

53.—De Bourmont, Chalet Saint François, Arcachon (Gironde), to seat four. Petroleum.

60.—Maurice le Blant (as above), brake, to seat nine. Steam.

61.—R. de Montais, Beauvoir près de Cloyes (Eure et Loire), to seat two. Petroleum.

62.—Mallarmé, 56, Rue Frileuse, Gentilly (Seine), to seat five. Steam.

64.—Panhard et Levassor (as above), to seat four. Daimler motor.

65.—Les Fils de Peugeot Frères (as above), phæton, 1894 type, to seat four. Daimler.

67.—Lebesque, 22 bis, Rue des Faillandiers, Paris, to seat four. Petroleum.

68.—Garnier et Delarnoy, Beauvois (Nord), to seat four. Combination of manual and mechanical motor.

71.—Th. Klaus, 20, Avenue du Grand Camp, Lyon (Rhone). Tricycle to seat two. Petroleum.

72.—Tamarelle-Capeyron, Bergerac (Dordogne) to seat five. Steam.

74.—Raoul Meyer, Chevenceau (Charente Inférieure), Quadricycle to seat two or four. Steam.

75.—Charles Dessaux, 329, Rue Saint Martin, Paris, tricycle to seat two or four. Levers.

77.—Reverseau, 2, Rue des Lions Saint Paul, Paris, to seat four to six. Automatic.

79.—A. Baudet, 7, Rue Paul Bert, Paris, wagonette-phæton, to seat two to six. Steam.

84.—Plantard, 21, Rue Rousselet, Paris, to seat four. Compressed air.

85.—Roger, 52, Rue des Dames, Paris, to seat two or four. Petroleum.

88.—Jeantaud, 51, Rue de Ponthieu, Paris, to seat five. Petroleum.

91.—Count Carli, Castelnuovo di Garfagnana, Italy, to seat two. Electricity.

99.—L. Bonnefilo, Valence d'Agen, Lot et Garonne, to seat two. Petroleum.

100.—Bellanger, 8, Rue des Noyers, Mans, Sarthe, to seat four. Automatic (?).

101.—Jean Mary, 19, Rue des Fermiers, Paris, to seat four. High pressure gas.

The vehicles up to 44 inclusive will be tried on Thursday, and those from 45 to 101, both inclusive, will be tried on Friday. It is possible that there may be a few vehicles to be tested on Saturday, but this will only occur if it is quite impossible to test them on one of the other days.

It will be seen that there is only one foreign competitor left in the list, and he is an Italian (No. 91). An electric motor vehicle was originally entered by a Mr. Garrard, of Birmingham, but it does not appear to have been actually built. Tuesday afternoon the lots were drawn to determine which vehicles are to run on each of the five routes for the preliminary tests on Thursday and Friday next. In future I shall refer to each carriage by its distinctive number, in order to avoid repetition of names as much as possible.

On analysing the list it will be seen that the competitors who are sending in the greatest number of vehicles are Messrs. Les Fils de Peugeot Frères, and Messrs. Panhard and Levassor—the latter firm has the sole right to manufacture and sell the Daimler motor in France and Belgium, and they have supplied the former firm with all their motors. It will thus be seen that at least ten vehicles will be fitted with the Daimler motor which you described on page 322, Vol. lxxv. I am as yet unable to state precisely how many more of the petroleum motors are of the Daimler type.

The entries may be divided as follow:—

| | |
|---|---|
| Petroleum motors, of which ten at least are Daimler ... | 23 |
| Steam ... | 12 |
| Levers ... | 2 |
| Steam and petroleum | 1 |
| Compressed air | 2 |
| Compressed gas | 1 |
| Electricity | 1 |
| Various | 4 |
| | — |
| Total | 46 |

Electricity appears to be nowhere; and, so far as I am able to judge at present, I believe the petroleum motors are most likely to succeed. I visited the works of Messrs. Panhard and Levassor on Tuesday morning, and was very kindly shown over the various shops by M. Panhard, jun., in the absence of the other partners, who were at the office of *Le Petit Journal*, engaged in drawing lots for their places at the trials.

I send views of some of the vehicles made by this firm, which I fear will be too late for this week's issue. The firm have bought the Daimler patent rights for France and Belgium, from Mr. Daimler, the inventor, who is a German, living in Stuttgart.

I was informed that Messrs. Panhard and Levassor have made, during the last four years, about 350 Daimler motors of various sizes, and that they have themselves built, and fitted with these motors, about ninety vehicles, all of which are in use in Paris or the provinces, and two in Belgium. Messrs. Peugeot have been supplied by them with at least eighty motors, so that it will be seen that the business done in this branch is very considerable. The increase during the last twelve months, I am told, is very large. In walking round the fitting shops, I saw parts of scores of these motors in progress, and the construction seems to form one of the chief branches of the business of the firm, although until recently they devoted themselves chiefly to the building of wood-working machines of various kinds.

The vehicles made by this firm, generally, have the motor placed in front, and in response to a question put by me as to the smell caused when working, M. Panhard took me to see a Daimler motor of 3·5 horse-power under test in an adjoining shop. Although the exhaust was perfectly open, and the pipe itself ended about 6ft. from the ground, so that the whole of the products of combustion were discharged into the building, I noticed no unpleasant smell. It appears that care must be used in the purchase of the oil, which is here known as "essence minerale." I saw at least a dozen vehicles ready to go on to the roads, and parts of about the same number in an unfinished state. I was also shown a vehicle provided with a steam motor designed by a M. Varennes, and entered for the competition. This gentleman, has, however, given up the idea of competing, and has purchased for his private use a vehicle built by Messrs. Panhard and Levassor, and provided with a Daimler motor.

It seems that a great sale is found for the vehicles to country doctors, who are able to do from forty to fifty miles a day, and in some cases the motor has taken the place of four horses, which had to be kept previously, in order to obtain a satisfactory service. The type sold to doctors is usually one to seat two persons, and the carriage is provided with the ordinary hood.

## IN THE ENGINE-ROOM OF THE LUCANIA.

In various issues of The Engineer, and at various times, we have written about the great Cunard steamships the Campania and Lucania, and in our impression for October 13th, 1893, we gave numerous engravings, reproductions of photographs taken on board, which are competent —as far as engravings can be competent—to furnish an approximate idea of what the ships are like. We have also in the same issue illustrated the engines, from a photograph taken in the erecting shop.

Now, accurate as photographs are, they entirely fail to reproduce mental impressions of size. Even when a man is introduced to act as a standard, the realisation of impression is quite inadequate. The views which we give this week are, on the other hand, the accurate embodiment of the impression produced on the mind of a man who is at once a highly competent artist and a trained mechanical engineer. His sketches do more, we think, to enable our readers to realise the vast dimensions of the machinery than anything else short of a personal visit to the engine-room could do. Again, it must not be forgotten that a photograph taken in an erecting shop gives an imperfect idea of the engine-room, because a host of appurtenances of various kinds are left out. They are not part and parcel of the main engines, but they are part of the machinery of the ship.

It will be well here to go over somewhat old ground, and supply a few particulars of the construction of the main engines. They are each intended to indicate 15,000-horse power, and that power has actually been obtained. We believe, however, that the average working power is 28,000-horse power for the two. They are peculiar in arrangement. Each engine has five cylinders and three cranks. There are two high-pressure cylinders 37in. in diameter. These stand each over a low-pressure cylinder, 98in. in diameter, a single piston-rod serving for each pair of pistons. Between the two low-pressure cylinders is placed one intermediate cylinder, 79in. in diameter, into the valve chest of which both the high-pressure cylinders exhaust. The stroke of all the pistons is 69in. The capacities of the cylinders are to one another roughly as 10 : 49 : 75. But, inasmuch as there are two low-pressure and two high-pressure cylinders to one intermediate, the real proportions come out very nearly as 21 : 49 : 150, or as 3·7 and 20·3. If steam were cut off at half-stroke in the high-pressure cylinder, and the effect of clearance neglected, the total expansion would be about 13·5 to 1. The safety valves are loaded to 165 lb., so that if we take the initial steam pressure as 175 lb. absolute, the terminal pressure would be a little under 13 lb. absolute. This is, of course, higher than that obtained in practice, for sufficiently obvious reasons. Various changes have been made in the propellers of the Lucania and Campania, and we do not know what is the precise number of revolutions made per minute now. We shall not be far wide of the mark, however, if we take it at a little more than seventy-one, corresponding to a piston speed of 800ft. per minute. The two high-pressure pistons have piston valves. The propellers are three-bladed, of manganese bronze, cast at Fairfield. The total weight of the six blades of the two propellers is 48 tons, which is the weight of about 5,500,000 pennies, the nominal value of which would be £22,916. We need scarcely add that pennies were not used for the purpose.

The first of our views, that given on page 54, shows the lower or starting platform, between the two engines looking aft. The sliding doors in the intermediate bulkhead are open. One excentric and a link are seen. The crank shafts are concealed by the frames and splashers.

The second view, on page 55, is taken on the second platform. One crosshead of the port engine is seen to the right in the picture, and a piston-rod of the starboard engine to the left.

The third view, on page 58, is taken at the level of the tops of the intermediate-pressure cylinders. A low-pressure valve chest occupies the lower right-hand corner; above it is seen the lever used for working the piston valve of the high-pressure cylinder, the rod of which can be seen entering the stuffing-box on the conical cylinder cover. The tail rod casing of the intermediate cylinder of the starboard engine can be seen to the left. Nearer is shown the stop valve, with its branch pipes going forward and aft to the high-pressure cylinders; the exhaust pipes from these to the intermediate valve chest are also very clearly shown. The central gangway is on the top of the central bulkhead, which is here high above the water-line.

The view on page 51 shows the Brown reversing gear, and gives a very good idea of the enormous scale on which every detail has been worked out. The group of views on page 62 will serve still further to convey an impression of the enormous size of the machinery, the most powerful ever constructed.

We may now proceed to give a few figures, which will serve to bring out this fact in sharper relief. The engines are 47ft. high from the base to the top of the high-pressure cylinders; that is about the height to the top of the roof of an ordinary three-storey house. The crank shafts are each made of three pieces, and each piece weighs 27 tons. The thrust shaft is 16ft. long, and weighs 29 tons; the crank shaft is 26in. in diameter; the propeller shaft, 24in. The total weight of crank and thrust shaft, taken as a whole, is 110 tons; each of the six connecting-rods weighs 10 tons.

No particulars have ever been made public concerning the quantity of coal used per day; but it is not difficult to arrive at fairly approximate figures, and these are startling enough. It is said that the City of Paris and City of New York—now the Paris and the New York—get on with 350 tons per 24 hours. This may or may not be the case; but it is easy to see that the Lucania and Campania must burn much more. As we have said, we believe it to be pretty certain that these ships each require 28,000-horse power to propel them at the enormous speeds which they so regularly maintain. The auxiliary engines in such a ship use a great deal of steam, which is not included in this 28,000-horse power. The main engines are no doubt economical, but we cannot think that we shall be far wrong if we take the weight of steam used, all referred to the main engines, as 16 lb. per hour per horse, which at 8 lb. of water per pound of coal, represents 2 lb. of coal per horse-power, a very good result under the circumstances. It is possible, of course, that the consumption may be less than this, the evaporation higher; but the one cannot be much less, nor can the other be much smaller.

Taking, then, the coal at 2 lb. per horse per hour, we have 56,000 lb., or 25 tons of coal per hour, or 600 tons a day. That is to say, the consumption per day equals the contents of two 30-wagon coal trains.

Through the engines will pass 8 × 25 = 200 tons of steam per hour, or $3\frac{1}{3}$ tons of steam per minute; the feed-water will require to pump it into the boilers about, when allowance is made for pipe friction, &c., 100 indicated horse-power. The feed-water, taking 36 cubic feet to weigh a ton, would fill a tank 10ft. wide, 10ft. deep, and 72ft. long.

To condense the 200 tons of steam about 7500 tons of water is pumped each hour through the condensers; that is to say, about one half the weight—displacement —of the ship. This water would fill a tank 20ft. wide, 10ft. deep, and 1350ft. long, or it would fill a dock 337ft. long, 40ft. wide, and 20ft. deep. Flowing over a weir, this volume of water would represent a not inconsiderable trout stream. It is moved, however, with a very small expenditure of power, because there is virtually no head against the centrifugal pumps.

In the boilers—twelve main and two auxiliary—there are 102 furnaces. In each there is nearly 26 square feet of grate surface, or, in all, 2625 square feet. That is the area of the floor of a great hall, 52ft. long, and 52ft. wide. Fifty tons of coal are required to charge the furnaces, and that is the quantity burning at one time. To burn 56,000 lb. of coal in an hour on these grates, about 25 lb. of coal must be burned per square foot per hour. This is not more than we should expect, seeing that the tops of the chimneys are 120ft. above the grate level, and that very special facilities have been provided for the supply of air to the fire-rooms, although forced draught is not employed. Allowing 20 lb. of air to burn each pound of coal, we find that 250 tons of air per hour must pass up each of the great chimneys, 19ft. in diameter, and 130ft. apart.

# DOCK IMPROVEMENTS AT LIVERPOOL

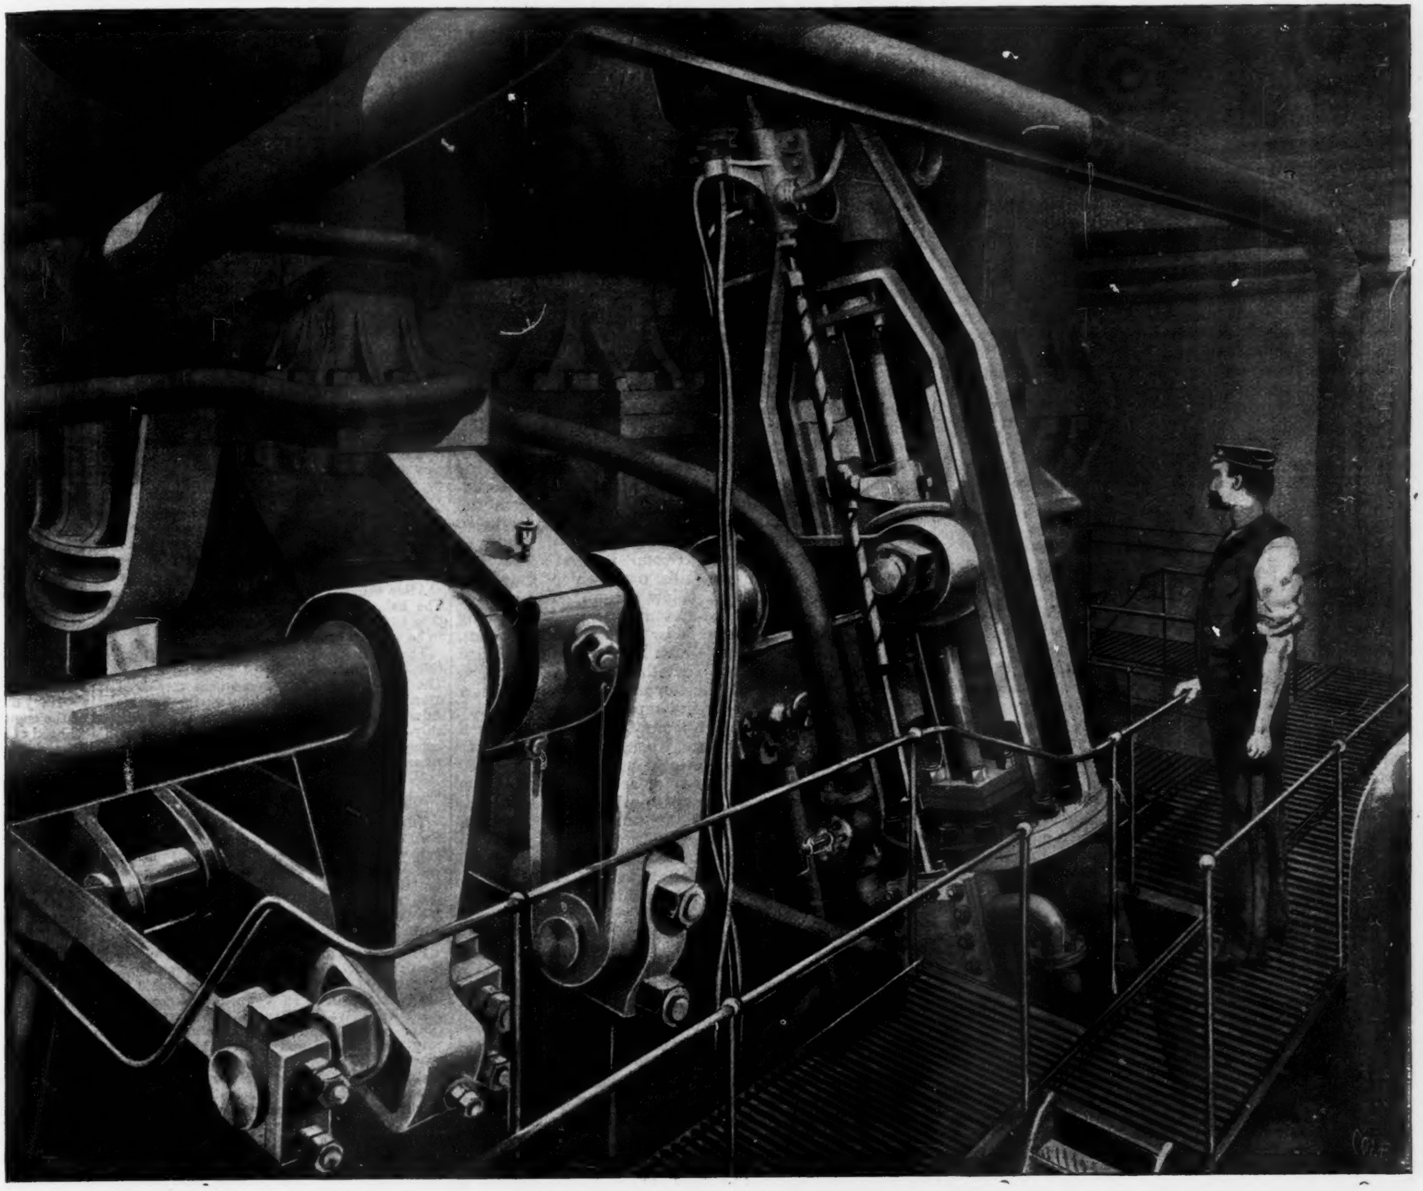
# THE ENGINE-ROOM OF THE LUCANIA—THE BROWN REVERSING GEAR

(*For description see page* 48)



This, at the probable temperature at the top of the funnel, would occupy a space of about 11,200,000 cubic feet.

The Campania has steamed from Sandy Hook to Daunt's Rock at an average speed of 21·28 knots per hour. But taking 21 knots as her velocity, she passes over 2130ft. per minute. In the same time her pistons make 800ft. The speed of the ship is thus 2·$\frac{2}{3}$ greater than that of the pistons. If we take the length of the passage as 2812 knots, then each piston passes over a space of 1057 knots, and as there are six pistons, the total distance they make is 6342 knots. Those of our younger readers who are fond of graphics may find it interesting to plot the path in space of one of the pistons from the data we have given. It will be seen that the relation between the speed of a piston and that of a ship is very important. It is evident, for example, that if half the whole power, or 14,000-horse power, were referred to the low-pressure cylinders of each engine, the average total pressure on the piston could not be less than $2\frac{2}{3}$ times half the resistance of the ship. But as in all probability the thrust effort, multiplied by the velocity in feet per minute, does not exceed one-half the whole horse-power, then the piston effort must be twice half the whole resistance. We say half the whole resistance, because there are twin screws. The total thrust on the two blocks will in all probability not much exceed 100 tons, or say 50 tons on each.

It will be seen that we have taken the consumption at 600 tons per day of twenty-four hours, and it may be said that this is an exaggeration, and that the consumption is really much less. This may be the case; but if so then either of four things must take place:—(1) The engines do not use 16 lb. of steam per horse per hour; (2) they do not indicate 28,000-horse power; (3) the boilers evaporate more than 8 lb. of water per pound of coal; or, (4) any two, or all three, of these suppositions are facts. Now as regards the first point. It will be admitted that a consumption of but 16 lb. of steam per horse per hour represents a very good engine indeed. We are quite aware that higher duties by four, or possibly five pounds have been attained, but not at sea, and only under almost exceptional circumstances on land. In this 16 lb. we have included, be it remembered, all the steam used in driving pumping, and electric lighting engines; for heating, and all the thousand-and-one uses to which steam is put in a great ship, and all used, be it observed, more or less uneconomically. As regards the second point, we have every reason to believe that the power exerted is more nearly 30,000-horse power than 28,000-horse power. There remains only the boilers to be considered. There is nothing about them specially economical; nor is Welsh coal used, nor is the feed-water supplied at a high temperature. We hold, therefore, that an evaporation of 8 lb. per pound of coal would be a very fair duty. But it will be seen that even if the boilers evaporated 9 lb. instead of 8 lb., it would only affect our calculations by one-eighth. The Cunard Company, following the example of the White Star, and indeed, of all other Atlantic companies, refuse to make their coal consumption known. We have, of course, no desire to break through this wall of reserve. But, on the other hand, it is open to all engineers to speculate, as we have done, on what the probable consumption of the ship must be, and we hold that if the entire horse-power in the ship, auxiliaries and all, is obtained at the rate of 2 lb. of North-country or American coal per horse-power per hour all round, the result is very satisfactory. Every passage across the Atlantic is in a measure a race against time, and little account of economy is taken as compared with speed.

It is now time to say something concerning the performance of these phenomenal ships, which have been steadily augmenting their speed almost from the first. Last November the Lucania held the record for the fastest westward passage across the Atlantic, the run being made in 5 days 12 hours 47 minutes, the average speed being 20·93 knots. The Campania, on the other hand, held the record for the quickest eastward passage, the run being made in 5 days 12 hours 7 minutes, or at an average speed of 21·28 knots. The figures are as follows:—

*Lucania's Westward Passage.*

| | Knots. |
|---|---|
| Daunt's Rock, 12.55 p.m., October 29th, to noon October 30th ... ... ... ... ... ... ... ... | 481 |
| October 31st ... ... ... ... ... ... ... ... ... | 542 |
| November 1st ... ... ... ... ... ... ... ... ... | 536 |
| November 2nd ... ... ... ... ... ... ... ... | 490 |
| November 3rd... ... ... ... ... ... ... ... ... | 535 |
| To 9.7 p.m., November 3rd, Sandy Hook Lightship | 196 |
| Total ... ... ... ... ... ... | 2780 |

*Campania's Eastward Passage.*

| | Knots. |
|---|---|
| Sandy Hook Lightship, 9.10 a.m., October 28th, to noon ... ... ... ... ... ... ... ... ... ... | 47 |
| October 29th ... ... ... ... ... ... ... ... ... | 491 |
| October 30th ... ... ... ... ... ... ... ... ... | 490 |
| October 31st ... ... ... ... ... ... ... ... ... | 491 |
| November 1st ... ... ... ... ... ... ... ... ... | 505 |
| November 2nd ... ... ... ... ... ... ... ... | 495 |
| To 1.5[illegible] a.m., November 3rd, Daunt's Rock ... ... | 293 |
| Total ... ... ... ... ... ... | 2812 |

These figures may be compared with those of the performance of the rival ships Paris and New York. They represent average, and not exceptional passages, for all four ships:—

*Average Passage.*

| | Queenstown to New York. | New York to Queenstown. | Knots per hour. |
|---|---|---|---|
| Campania ... ... | 5 d. 20 h. 18 m. | ... ... ... ... | 20·06 |
| | | 5 d. 17 h. 27 m. | 20·76 |
| Lucania ... ... ... | 5 d. 14 h. 27 m. | ... ... ... ... | 20·64 |
| | | 5 d. 20 h. 50 m. | 19·90 |
| | Southampton to New York. | New York to Southampton. | |
| Paris ... ... ... | 6 d. 15 h. 14 m. | ... ... ... ... | 19·30 |
| | | 6 d. 22 h. 23 m. | 18·65 |
| New York ... ... | 6 d. 20 h. 50 m. | ... ... ... ... | 18·66 |
| | | 6 d. 20 h. 30 m. | 18·89 |

There is, however, a later performance than any of those we have given. The following extract from the *Liverpool Mercury*, of May 28th, 1894, gives the particulars of a very remarkable round trip made by the Lucania:—"The westward passage across the Atlantic is usually the most trying and protracted, but on rare occasions a vessel will carry easterly winds with her throughout it. The record passage in that direction was 5 days 12 hours 47 minutes, on the northerly route for a total distance of 2780 knots. The passage has now been made in only ten minutes longer time on the southerly route of 2873 knots, or a greater distance by ninety-three knots. It has been done, too, in spite of the fact of six hours' fog being encountered, during which the vessel proceeded at reduced speed. On the 19th instant, the American Line steamer New York took her departure from the Needles at 1.35 p.m. The Cunard steamer Lucania took hers about twenty-three hours later from Daunt's Rock, Queenstown, and arrived at Sandy Hook Lightship about four hours sooner, having averaged over two knots an hour greater speed than her American competitor. The Lucania now excels all records in ocean steaming, in having made the round trip from New York and back again at an average speed of 21¾ knots per hour over a distance of 5784 knots. The fastest railway express in the world could not thus maintain an average speed of 25 miles an hour over a distance of 6660 miles, with only one break on the journey. Had the Lucania sailed on the short route, on which her record voyage was made, her passage would have been 5 days 8 hours 39 minutes. Her sister ship, the Campania, has already averaged close on to this speed on one trip, but on her present homeward voyage met with easterly gales and high confused seas throughout the passage, besides some fog, through which she was delayed leaving New York beyond her ordinary time. Nevertheless, her passengers, the largest number that ever left New York so early in the season, were landed in Liverpool on Saturday afternoon."

Although we have already very fully described the Lucania, it may be convenient to reproduce here the following figures which serve to emphasise the progress which has been made in Atlantic navigation. The first steamer possessed by the Cunard Company was the wooden Britannia, which started on her first voyage—to Boston—from the Mersey on the 4th of July, 1840—that is to say, just 54 years ago.

| | Britannia. | Lucania. |
|---|---|---|
| Length ... ... ... ... | 207ft. | 620ft. |
| Tonnage... ... ... ... | 1150 | 12,950 |
| Horse-power... ... ... | 740 | 30,000 |
| Speed ... ... ... ... | 8½ knots | 21½ knots |
| Consumption of coal per day... ... ... ... | 38 tons | 600 tons |
| Passage ... ... ... ... | 14⅓ days | 5½ days |
| Accommodation ... ... | 115 passengers | 1400 passengers |

The crew of the Lucania is divided into three departments, and numbers all told, sailing 54 hands, engineers and firemen 190, and stewards 179, total 423 hands.

It will be readily understood that such ships as the Lucania and Campania cannot properly be utilised unless the dock accommodation provided for them is adequate. Vast, however, as is the system of Liverpool Docks, it can scarcely be said that they are wholly satisfactory. Very considerable improvements have, however, been in progress for some time at Liverpool under the direction of Mr. Lyster, to whom we are indebted for the plan on page 50, and for the following information. The improvements are being effected in the Canada, Huskisson, and adjoining docks.

The Canada Lock, forming the northern entrance into the Canada and Huskisson Docks, will be lengthened to 602ft., while its present width of 100ft. will be retained. It will be deepened by 5ft. 9in.—*i.e.*, to 14ft. below Old Dock Sill, or 2ft. below the level of the sills of the Langton entrances. The floor of the chamber of the lock and the sills will be very flat in cross section, to suit the modern type of vessels. The bottom of the Canada Basin in the approaches to the lock will be at least 14ft. below Old Dock Sill. An open timber jetty will be constructed across the south-east corner of the basin, and in its base sluices will be provided. By means of these and the existing sluices the proper depth will be maintained in the basin.

The Canada Dock is to be extended southwards, the western quay being straightened so as to afford 1090ft. of straight berthage. On the east side of the dock, at its south end as extended, a new branch dock 300ft. wide will be constructed, parallel with and similar to the Huskisson Branch Dock No. 2. The new quays of the dock and branch dock will have sheds of the latest type on them. That on the south quay of the branch dock will be a double-storey shed of the same class as that on the east quay of the Toxteth Dock. One of the novel features of these sheds is that the discharge of cargo from the vessels alongside them is effected by quick working hydraulic cranes of a design patented by Mr. A. G. Lyster. These are placed on the wharf, and are capable of being moved from place to place as required. The shed on the south key of Canada Branch Dock will be 1360ft. long and 95ft. wide. The upper floor is of tiles and concrete on buckled plates, carried by wrought-iron girders, the columns supporting the same being spaced very wide apart, so as to present the least interference possible with the cargo and the cartwork in connection with it, which is a great feature of the traffic at the Liverpool Docks. The framing of the roof is also of iron, and the covering is of Welsh slates.

The other buildings at these new quays, where there is more space available, are single storey sheds; that on the west quay of the Canada Dock being 1122ft. long and of 115ft. wide for a considerable portion of its length, and that on the north quay of the Canada Branch Dock being 1044ft. long by 125ft. wide for 782ft. and 94ft. wide for 262ft. The new passage between the Canada and Huskisson Docks will be 90ft. wide, with a sill laid at such a level as to give an efficient approach to the Huskisson Dock.

A new half-tide dock will occupy the site of the Sandon Basin and Wellington Half-tide Dock. It will have three entrances from the river, one 100ft. wide, one 80ft. wide, with their sills laid at the level of 20½ft. below Old Dock Sill, which will allow of the largest vessels, such as the Lucania, entering or leaving it on all tides; a smaller passage, with locks, will also be provided for the use of flats and small craft. On the site of the present 80ft. lock entrance to the Huskisson Dock, a new deep entrance, 90ft. wide, will be formed, and on the site of the 45ft. lock entrance will be built a new deep water graving dock, 750ft. long, and having an entrance 90ft. wide.

It is not proposed to alter the depth of the Huskisson or Sandon Docks, or of those southward of the new half-tide dock, but after the completion of that dock they, as well as the Canada and Huskisson Docks, will be impounded over low neap tides, and the whole thus formed into a deep water system, the water being maintained at any desired level, so as to give flotation to the deepest draught vessels in them. The half-tide dock will be worked in the ordinary way to the tide of the day. Soon after high water the outer gates will be closed, after which the half-tide will be levelled up, so as to allow of the free passage of vessels throughout the system.

By this scheme a very large amount of quayage which, by reason of the comparative shallowness of the docks, their entrances and approaches, is not now available for vessels of the deepest draught, will be brought into full use for such vessels at all tides. This is following a system which has been largely adopted at Liverpool, where the demand for deeper water has been answered by adopting the method of impounding and pumping, in preference to any works of re-construction of the old docks, which would necessarily be exceedingly costly, and throw the docks in question out of commission for long periods. The pumping and impounding system has been fully described by Mr. Lyster, as in use at the Brunswick-George's Group at Liverpool, and in the Birkenhead Docks on the other side of the Mersey.

The pumps at Coburg Dock were provided in 1889 with the object of maintaining, during neap tides, an abnormal level of water in the group of docks from Brunswick to George's inclusive. The sills and bottoms of these old docks being laid at levels about 6ft. below Old Dock Sill datum, under normal conditions no vessel drawing more than about 16ft. could remain afloat in them during neap tides. In order, therefore, that they might be constantly available for modern deep-draught vessels, the water is impounded in them over low neap tides, and the installation of pumps now in question takes water from the river into the docks to make good losses by leakage, lockage, &c. By these means the effective depth of the Brunswick - George's Group is made not less than that of the lowest sills over which they can be approached, viz., 12ft. below datum. The passage to and from the impounded system for vessels requiring the extra depth of water is by way of Herculaneum, Harrington, Toxteth, and Union Docks, the last named serving as a lock from the Toxteth Dock at tidal level to the Brunswick Dock at the impounded level. Shallow draught vessels can enter the impounded group by way of the Brunswick half-tide, Coburg, Queen's half-tide, and Canning half-tide, which are, when required, opened to the tide of the day, and levelled up to the impounded level after high water. The total area of the docks in the Brunswick-George's Group to which the additional depth of water is given is seventy-nine acres. A similar installation of pumps at the Wallasey Dock, Birkenhead, erected in 1890, provides the required additional depth for docks there, in which a similar condition of old shallow sills obtains, the area affected in this case being about 160 acres.

The contract for the machinery required that the pumps should be capable of raising 11,400,000 gallons = 1,824,000 cubic feet, through a height of 10ft. in one hour, and this requirement was more than fulfilled. In the trials made, the maximum discharge in any fifteen minutes was at the rate of about 1200 tons per minute for the three pumps, this being through a mean height of 7¼ft. In each case there are three centrifugal pumps driven by vertical inverted compound condensing engines, arranged tandem fashion, and independent of each other, providing the pumping power. The main dimensions of the engines are as follows:—

| | |
|---|---|
| H.P. cylinder ... ... ... ... ... ... | 22in. diameter. |
| L.P. cylinder ... ... ... ... ... ... | 40in. diameter. |
| Stroke ... ... ... ... ... ... ... ... | 30in. |
| Revolutions ... ... ... ... ... ... ... | 90 per minute. |
| And of the pumps— | |
| Fans ... ... ... ... ... ... ... ... | 90in. diameter. |
| Suction and delivery pipes ... ... ... | 54in. diameter. |
| Pump casing... ... ... ... ... ... ... | 16ft. 6in. |

This plant was provided by Messrs. J. and H. Gwynne, of Hammersmith Ironworks, the pumps being of the "Invincible" type. Steam is provided by five Lancashire steel boilers, 30ft. long and 7ft. 6in. diameter. Each flue has four Galloway tubes. The working pressure is 100 lb. to the square inch. The feed-water is passed through a Green's economiser, having five groups of sixty-four pipes each.

Before concluding, we have to express our thanks to the Cunard Company, and especially to Mr. Arthur Moorhouse, the secretary, and to Mr. Bain, the superintending engineer, for the facilities for sketching afforded our special artist. To Mr. Lyster also we have to express our obligations for the information concerning the new dock works.

WRECK RAISING.—The prospectus is issued, as will be seen from our advertisement pages, of the British Wreck Raising and Salvage Company. The object is to undertake salvage of all descriptions of sunken vessels. The capital is to be £100,000 in £5 shares.

HARBOUR WORKS FOR VERA CRUZ.—According to a recent Foreign-office report, the construction of the sea wall for the protection of Vera Cruz Harbour from the heavy seas that during the winter months have so constantly impeded the works in the bay is progressing. The foundation of the outside casings of the wall across the north passage, between the shore and the island of Ulna, is almost completed; but the coping has been nearly all destroyed by the waves. Up to March 2nd, 590ft. of the foundations for the inside casing or wall have been laid, and there remain but two tiers of blocks to be completed before the coping. Sand dredged from the bay is being deposited between these two casings, to fill in the wall. The silting of the sand in the bay, owing to the stoppage of the north passage, is a serious matter. The sand has collected to the southward, and is threatening the Customs Pier. The shoal water at the piers often stops work, lighters being prevented from going alongside the piers through broken water and want of depth. Unless preventive measures are taken in time, much damage may be expected. A hopper dredger and sand pump capable of dredging 200 tons per hour, and of carrying 300 tons in her deposit, has commenced constant work, and is to be supplemented by another. To prevent the entrance of sand from the north, the passage left in the breakwater for the current to pass is to be blocked. There is already a return for the capital and labour expended on the enterprise, and vessels can discharge during weather which previously would have stopped all communication with the shore. As the work proceeds, the number of weather working days in Vera Cruz increases.

## H.M.S. FERRET.

THE official trial of H.M.S. Ferret, built by Messrs. Laird Brothers, of Birkenhead, took place on the Clyde on Tuesday, the 10th inst., in the presence of Mr. Deadman and Mr. Pledge, representing the Constructors' Department of the Admiralty, and Mr. Ellis, the Engineer-in-Chief, and Mr. Hobbs, of Devonport Dockyard. The builders were represented by Mr. J. M. Laird and Mr. R. R. Bevis, jun.

The following tables give the results as recorded for the runs on the mile and for the three hours' continuous steaming, and the regularity of the performance throughout is especially worthy of notice:—

*Six Runs on Measured Mile.*

| Miles. | Steam. | Vacuum | Revs. | Ind. H.P. | Speed in knots | Means. | Second means. | |
|---|---|---|---|---|---|---|---|---|
| 1 | 170 | 25·2 | 351·0 | 4127 | 26·866 | — | — | |
| 2 | 168 | 25·0 | 356·9 | 4375 | 27·170 | 27·018 | 27·178 | 27·612 |
| 3 | 173 | 24·8 | 363·3 | 4542 | 27·506 | 27·338 | 27·581 | |
| 4 | 175 | 24·8 | 369·6 | 4671 | 28·125 | 27·825 | 27·820 | |
| 5 | 172 | 24·8 | 364·1 | 4656 | 27·506 | 27·816 | 27·871 | |
| 6 | 175 | 24·5 | 373·2 | 4672 | 28·346 | 27·926 | — | |
| Means | 172·17 | 24·85 | 363·0 | 4507 | — | — | — | 27·612 |

*Six Half-hours.*

| Half-hours. | Steam. | Vacuum. | Revs. | Indicated horse-power. | | | Speed. |
|---|---|---|---|---|---|---|---|
| | | | | Starb'd. | Port. | Total. | |
| 1 | 173 | 25·0 | 350·1 | 2184 | 2137 | 4321 | Mean speed of ship, 27·51 knots. |
| 2 | 175 | 24·75 | 362·3 | 2367 | 2269 | 4636 | |
| 3 | 170 | 24·75 | 365·1 | 2411 | 2399 | 4810 | |
| 4 | 171 | 24·5 | 362·4 | 2304 | 2204 | 4508 | |
| 5 | 161 | 24·75 | 361·0 | 2222 | 2112 | 4334 | |
| 6 | 163 | 24·75 | 359·5 | 2189 | 2145 | 4334 | |
| Means.. | 169 | 24·75 | 360·07 | 2279·5 | 2211 | 4490·5 | 27·51 |

The three hours' trial was commenced at 10.15 a.m., the vessel having her full normal weight on board, the coal in bunkers being 26 tons, and the average speed for the whole time was found to be 27·51 knots, with 361 revolutions.

After the run, the usual trials as to manœuvring were made. The helm was put from hard over to hard over both ways in less than twelve seconds each at full speed, and the steering was proved to be entirely satisfactory.

There was a remarkable absence of vibration when running at full speed, and no hitch of any kind occurred in the machinery. The speed for the six runs on the measured mile is the highest ever yet recorded by any vessel for her Majesty's Navy on the Admiralty official trial, and seeing that the speed of the engines is only 361 revolutions per minute, there seems no likelihood of there being much difficulty in maintaining this at future times when the vessel is in commission.

THE INCORPORATED ASSOCIATION OF MUNICIPAL AND COUNTY ENGINEERS.—At the annual meeting in London, in June, it was suggested that an endeavour should be made to hold a meeting of the Association in Brussels during the month of August, and at the Council meeting held on the 7th inst. it was decided that such meeting should be held, and that members should leave London on August 17th, subject to necessary arrangements being made in Brussels.

PHOTOGRAPHIC TRACINGS.—We have received from Messrs. Smith and Co., Manchester, some samples of their new "Simplex" sensitised paper, for making photographic tracings with black or nearly black lines on a white background, instead of the blue prints or mauve lines on an imperfectly white paper. The new paper provides the means of obtaining copies of tracings in a very easy manner, and with great clearness. Its chief advantage over the gallic acid and cyanotype processes lies in the fact that it only requires a water bath for development, no chemicals being required. After being sufficiently exposed in the usual way, it is simply immersed in clean water, and in about a minute the lines come out black. To be able to dispense with chemicals is a great advantage, and a good clear black line has been much wanted. There is no doubt this paper will rapidly find favour among engineers and architects.

PARIS EXHIBITION.—Thirty-six projects for what is called the Clou, or main attraction, of the Paris Exhibition for 1900 have been sent in to the special sub-committee. The well-known engineer, M. Armengaud Jeune, proposes the offering of handsome prizes for solutions of the three problems, transmission of sight to a distance, chromo-photography on paper and electric lighting without focus, by cold light with the aid of electric undulations of great frequency. M. Flammarion, the astronomer, proposes a shaft showing the various geological epochs with their inhabitants, and also an arrangement by which the spectator would witness the revolution of the earth as if from the surface of the moon. M. Trouvé, the electrician, advocates a luminous cascade falling from the upper platform of the Eiffel Tower and also a luminous fountain rising to the same height. A bridge, 100 metres, or 330ft. wide, is to be thrown across the Seine opposite the Invalides, and lined on either side with houses and shops like the old Pont Neuf and Old London Bridge.

LONDON ASSOCIATION OF FOREMEN ENGINEERS AND DRAUGHTSMEN.—The half-yearly meeting of this Association was held in the K Room of the Cannon-street Hotel on Saturday, the 7th inst., at 7 p.m., when the president, Mr. W. H. Bale, occupied the chair. The balance-sheet for the past half-year was submitted, showing the total amounts standing to the credit of the Association on June 30th was £4816 12s. 11½d., and the net increase during the half-year £124 9s. 1d. The auditor reported the books well kept, and the accounts correct, and the president having expressed satisfaction with the result, the balance-sheet was adopted unanimously. After some general business was disposed of, a lecture was given by Mr. Wm. T. Coates, past-president, on "Modern Technical Education." Mr. Coates said he had attended the recent conference in the County Council offices, and was disappointed with the result so far as it concerned the training of engineers. As at present conducted, technical education is a misnomer, as it did not make those taught better workmen, but more often caused foremen much trouble in their endeavour to get work done in a reasonable time, as in schools and colleges the teachers did not appear to consider the time element at all. He was strongly in favour of youths and men being taught the principles of their trade, chemistry, mathematics, drawing, &c., so as to improve their intelligence and increase their aptitude for receiving and carrying out instructions; but was decidedly against actual work being undertaken, especially under the tuition of men with little workshop experience. Several members expressed opinions on the subject more or less in accord with the views of the lecturer, the general feeling being favourable to the old method, by which a youth worked in the shop during the day, learning to use his hands and tools, and in the evening attended classes where he learned to use his brains and utilise them in the assistance of his hands. One gentleman stated that the facilities for obtaining instruction were now so good, and the conditions of labour so much improved since his youth, that if men did not learn to be good workmen it must either be because of natural inability, indifference, or disinclination to make the extra exertion required from all who would obtain knowledge. The proceedings closed by a hearty vote of thanks being awarded to Mr. Coates for the way he had brought the subject before the meeting.

## RAILWAY MATTERS.

The formal opening of the West Highland Railway has been postponed.

The directors of the Gloucester Railway Carriage and Wagon Company have recently appointed as assistant manager Mr. John W. Howard.

The construction of a line from Stavropol to Caucaskaia has lately been completed, and the railway is now being extended from Caucaskaia to Bogaty-Rodnik, about seventy-six miles.

The construction of the railway from Acre to Caiffa and Damascus is completely at a standstill, owing to delayed negotiations between the contractors and an American syndicate. Only the first eight miles have been completed.

The railway from Beyrout to Damascus will not, it is expected, be opened for traffic before the end of 1895, in consequence of difficulties of a technical character, as well as obstacles in the way of obtaining possession of the necessary lands.

The officers of the roadway department of the Union Pacific Railway in Oregon, which was recently washed out, estimate the total loss at 375,000 dols., or less. About half of this is the damage to the road bed, and the rest is to cover damage to cars and engines and loss of business.

A concession for the construction of a line from Beyrout to Biredjik, on the Euphrates, has been obtained by the Compagnie du Chemin de Fer de Beyreuth-Damas. The line will be about 360 miles long. Surveys are being made, but the construction will take eight or ten years.

The Boston Elevated Railroad Bill has finally been passed by the Massachusetts Legislature, and been signed by the Governor. It is also called the Meigs Railroad Bill. There is a provision requiring the whole question to be referred to the voters of Boston before the law can take effect.

A large railway project is said to be on foot in Japan, which will connect Tokyo and Yokohama with Kyoto and Osaka, traversing such rich industrial districts as Tajimi and Nakatsugawa, in the province of Mino. The total distance of the line is estimated at 338¾ miles, and the cost at 21,000,000 dols.

In connection with the London and North-Western tunnel extensions in Birmingham, arbitration is proceeding to assess the compensation to be paid by the company to the trustees of Sir Josiah Mason's Orphanage for property which has been taken by the company compulsorily. The area is 2168 yards. The jury awarded £18,463.

We have received from the Street Railway Publishing Company the first number of "American Street Railway Investments," being a supplement to the *Street Railway Journal*. Its object is to give greater publicity than has hitherto been possible to the condition of street railway securities, and thereby ensure for them a quicker and readier market.

The Budapest Electric Conduit Railway, the success of which has been so often referred to, parts of which have been in operation for nearly five years, has a length of about 7·628 miles of double track, with which are connected about 3·26 miles of double track overhead trolley lines, and about 4·16 miles of single track line, operated by steam motors. The rolling stock consists of eighty-two motor cars and ten trailers for the electric roads and five locomotives, nine passenger and three freight cars for the steam lines. The electric system is run with 300 volts, all of the dynamos being connected to omnibus bars. The leads are made of lead-covered cables, armoured with iron bands and laid directly in the earth. They lead to junction boxes, from which others run along the road, and are connected at intervals by means of short branch conduits to iron leads in the main conduits, which are much like light cable road conduits. They carry two angle-bar conductors, one positive and one negative, from which the current is taken by a double collector projecting down from the car body through a slot rail into the conduit.

There has been for some time an effort to supply the demand in America for a good oil fire-kindler, and a device invented by Mr. J. S. Leslie, of Paterson, N.J., is now being successfully used on several railways. It deserves notice on account of its efficiency, cheapness, and convenience. The *Railroad Gazette* says:—When a fire is to be kindled, sufficient coal is thrown into the fire-box to cover the grate thoroughly, a burner, with two small flexible pipes attached—one each for air and oil—is connected by suitable hose couplings to the combination valve; then, by opening the combination valve, the oil is supplied automatically, and the air and oil are simultaneously admitted to the burner. A small piece of greasy waste is then lighted and thrown into the fire-box on top of the coal; the air and oil are then turned on to the burner by their respective valves, and the necessary quantity of oil is fed automatically by the air pressure, thus making it practically impossible to injure the fire-box sheets by overheating. When the fire has been kindled, the combination valve is closed, and the supply of air and oil is cut off. The oil remaining in the pipe is then automatically returned to the auxiliary tank, after which the burner is disconnected.

On the Northern Railroad of France some experiments were recently made with Serve ribbed boiler tubes in a stationary boiler of the locomotive pattern. In this boiler the grate had an area of 14·4 square feet; the old plain tubes were 166 in number, 1·97in. diameter, and 14·65ft. in length. The heating surface in the furnace had 82 square feet, and in the tubes—before alteration—1151 square feet; the steam pressure was 92·4 lb. per square inch. The boiler under trial was tested alone, and also when working along with the other boilers. The first Serve tubes tried were 2in. diameter and had ribs of a depth of 0·43in., which raised the heating surface from 1233 square feet to 2336 square feet, but reduced the section open to the passage of the gases from 2·84 square feet to 2·56 square feet. The *Engineering and Mining Journal* says that with natural draught the vaporisation per lb. of coal was very slightly increased, the same amount of steam being made in the day with a somewhat reduced consumption. With forced draught, however, the production of steam per lb. of coal was increased by as much as 12·5 per cent., the best effort being got with a draught pressure lying somewhere between 1¼in. and 2¼in. of water. The temperature in the smoke-box was lowered from 518 deg. F.—with smooth tubes—to 338 deg. The temperature of the steam being 322 deg., it is seen that very little more use could possibly have been made of the combustion. The objection, however, to this experiment was that the tubes often got choked with ashes; and therefore a tube of 2·05in. diameter was tried with with ribs 0·35in. in depth, the ribs extending to a length of 8·2ft. only, and the rest of the tube being smooth. The section for the passage of gases was now increased to 2·69 square feet, and less choking of the tubes occurred; the efficiency was much the same as in the preceding case. Tubes of the same size were therefore tried ribs of 0·275in. projection, both extending the whole length of the tube, and also for a length of 8·2ft. only. The results were much the same, whether the rib was of the full length of the tube or not, and showed a vaporisation of 25 per cent. in excess of that of smooth tubes for the same amount of fuel, with a draught of 3in. water pressure. With tubes of this depth all difficulty as to choking disappeared. With the shallower ribs, it was found that a greater draught gave maximum economy than with deeper ribs. The tubes used in these trials have now been fitted on two locomotives under repair, with an increase of weight in one case of 154 lb., and in the other of 220 lb. Fresh experiments in service with these locomotives are now in progress.

## NOTES AND MEMORANDA.

The deaths registered during the week ending the 7th inst. in thirty-three great towns of England and Wales corresponded to an annual rate of 16·1 per 1000 of their aggregate population, which is estimated at 10,458,442 persons in the middle of this year. Croydon and Leicester were phenomenally low, their rates being only 7·9 and 9·6 respectively. Salford was highest and worst with 23·6.

According to a method of detection of traces of chlorine, by MM. A. Villiers and M. Fayolle, the chlorine is liberated by permanganate in presence of sulphuric acid, and shows, *Nature* says, even in small traces, a blue coloration, becoming red-violet when treated with the following reagent in excess: saturated aquaeous solution of colourless aniline 100 cc., saturated aqueous solution of orthotoluidine 20 cc., and glacial acetic acid 30 cc.

At a recent meeting of the Paris Academy of Sciences, a paper was read on "The Principle of Maximum Work and Entropy," by M. Berthelot. A general discussion of the theory of maximum work, treated under the heads—(1) Chemical action and the disengagement of heat; (2) the principle of maximum work; (3) entropy; (4) a comparison of the consequences of the principle of maximum work and those of entropy.

The following has been given in the *Papier Zeitung* as cement for leather belting, in addition to those published last week:—250 parts of gold size, 60 parts of isinglass, and 60 parts of gum arabic are boiled in a water-bath until a homogeneous mixture is formed; 5 parts of Venetian turpentine, 6 parts of turpentine oil, and 10 parts of spirits of wine are then added. The joint, after cementing, is pressed between hot plates and allowed to get quite cold before the pressure is removed.

In London, during the week ending the 7th inst., 2254 births and 1314 deaths were registered. Allowing for increase of population, the births were 329, and the deaths 239, below the average numbers in the corresponding weeks of the last ten years. The annual death-rate per 1000 from all causes, which had been 16·0, 16·0, and 15·4 in the preceding three weeks, increased again last week to 15·8. During the four weeks ending on Saturday last the death-rate averaged 15·8 per 1000, being 2·0 per 1000 below the mean rate in the corresponding periods of the ten years 1884-93. In Greater London 3095 births and 1656 deaths were registered, corresponding to annual rates of 27·1 and 14·5 per 1000 of the estimated population. During last week the London death-rate rose to 16·3, against 15·9 for the thirty-three great towns.

The beautiful colouring of certain varieties of glass now produced in Germany, and which is said to far excel some of the most noted French specimens, is an art practised, by the glass-blower at the furnace, by means of an apparatus consisting of a sheet iron cylinder 20in. long and 8in. diameter, standing vertically, and having a similar cylinder riveted across the top. In the lower cylinder is an opening into which an iron ladle can pass, and the horizontal cylinder is provided with doors at either end, the one nearest the operator being so arranged that the blowpipes can be supported, when the door is closed, in a horizontal split running to its middle, the object to be treated being held inside. While the glassblower is re-heating his work for the last time in the furnace, an attendant takes the long-handled iron ladle, which has been heated red hot, shakes into it about a spoonful of a specially prepared chemical mixture, and places the bowl of the ladle quickly in the opening provided for it in the vertical cylinder. The *Society of Arts Journal* says the mixture immediately gives off vapour, which rises to the horizontal cylinders, where, meanwhile, the blower has placed his work, supported by the blowpipe and heated to an even red, turning it rapidly in the vapour. In a short time the object is covered with a changeable lustre, is removed from the pipe and tempered like other ware in an ordinary oven, then cut, engraved, painted, or gilded as desired.

"The Conditions in which Carbon exists in Steel" was recently the subject of a paper before the Chemical Society, by J. O. Arnold and A. A. Read. The authors have carried out experiments on the condition in which carbon exists in normal, annealed, and hardened steels on a series of five steels containing 0·96, 0·57, 0·33, 0·16, and 0·06 per cent. of carbon respectively. From the results of a number of experiments the authors draw the following conclusions:—(1) The existence is confirmed of a carbide of iron possessing the formula $Fe_3C$, originally discovered by Abel and Müller by independent methods. (2) The normal carbide exists in two different forms identical in chemical composition. (*a*) A diffused carbide is scattered in granules or very small plates throughout the iron in normal steel. When isolated it is a greyish-black powder. (*b*) A crystalline carbide, arranged in comparatively large distinct plates in well-annealed steel; these plates are chiefly in the form of well-marked striæ, and consist of pure $Fe_3C$. They are identical with the microscopical laminæ of Sorby's "pearly" constituent, and they may be isolated as bright silver plates. (3) The percentage of the total carbon obtained as carbide is greater in hard than in soft steels. (4) The above-mentioned loss does not appear to be due to decomposition, but rather to the presence of a readily decomposed subcarbide of iron—containing less carbon than the normal compound—existing to the extent of about 25 per cent. in mild steel, and capable of existing to the same amount in cold hard steel after the latter has been heated for some time at a white heat. (5) The loss being practically the same in well-annealed steel as in the normal steel, it cannot be due, as supposed by Ledebur, to the presence of "hardening carbon." (6) The carbon in hardened steel exists chiefly as an extremely attenuated carbide, or in solution, leaving on isolation a residue consisting mainly of "hydrate of carbon," mixed to a slight extent with carbide of iron.

We have before briefly alluded to the peculiar features attending the spreading of oil upon water, as set forth by M. M. Richter. We now read in *Nature* that this tendency is only due to the free oleic acid contained in the oil, and that if it were possible completely to purify it from oleic acid, it would not spread at all—which statement endorses our previously expressed views. The following experiment is described in the above-mentioned source:—Provence oil was shaken up twice with pure alcohol, the rest of the latter being carefully removed, and a drop of oil was placed upon the freshly formed water-surface in a small dish by means of a brass wire previously cleaned by ignition. The oil did not really spread, but after a momentary centrifugal movement, during which several small drops were separated from it, it contracted itself in the middle of the surface, and a second drop deposited on the same vessel remained absolutely motionless. Of course the surrounding water-surface proved to be in the anomalous state, the tension determined by the method of separating weights being = 0·82 of the normal value. It has been diminished by the "solution current" of the oil—as is called the "contaminating" current when issuing from a body in contact with a clean water-surface—which may be observed if the surface be dusted over with sulphur or lycopodium before placing the oil upon it. The observation of the solution-current, preceding unpurified oil, is more difficult, because the oil itself covers rapidly the whole surface. As soon as the relative tension 0·82 is attained, the slightest trace of a solution current ceases, whilst ordinary oil still shows solution-currents at much lower tensions. The surface-tension 0·82 is the lowest possible that can be produced on water by pure Provence oil; the surface then may be considered as saturated with oil. Evidently the pure oil does not spread over a surface of the minimum tension attainable by its contact with water, because the sum of its surface-tension and the interfacial tension of oil and water, which we may call "tension of equilibrium," is greater than the minimum tension. Therefore upon a clean water surface the oil is repulsed by its own solution current.

## MISCELLANEA.

The French Naval Manœuvres commenced at Havre on Tuesday morning, the 17th inst.

The new channel leading into Alexandria Harbour, having a depth of 28ft., was officially opened on the 2nd inst., and the harbour lights are now shown from sunset to sunrise.

The new packet-boat Ernest Simons, built for the Messageries Maritimes Company, attained a speed of 18 knots on her trial trip. She has a displacement of 6950 tons, and her engines are of 6000-horse power.

The 37mm. (1·46in.) one-pounder Maxim automatic gun has been tried on board H.M.S. Hero with satisfactory results. It weighs 364 lb., the mounting weighing 336 lb. The shell weighs 1 lb., the powder charge 2·8 oz., and the cartridge case 4·6 oz., so that the total weight of cartridge is 1·46 lb.

The Department of Science and Art has received, through the Foreign-office a despatch from her Majesty's Consul at Bordeaux calling attention to an international exhibition of arts, industries, &c., which it is proposed to hold in that city in 1895, under the patronage of the French Government.

An International Grain and Seed Fair will be held on the 27th and 28th August next at the Exchange for Agricultural Produce—formerly Corn and Flour Exchange—in Vienna. All interested in the grain and flour and allied trades are cordially invited to participate in the fair. Particulars can be obtained on application to Die Kammer de Börse fuer landwirthschaftliche Producte in Wien.

The Cambridge Electric Supply Company give notice that, on and after the 8th day of October next, an uninterrupted supply of current will be available at all hours of the day and night throughout the year. It certainly ought to endeavour to make some reparation to the Cambridge townsfolk for the erection of a chimney which is one of the greatest blots we have ever seen in a landscape. A stranger in the place might have thought that a very large and constant supply day and night had long been available, judging by the size, ugliness, blackness, and smoke emitting powers of this chimney.

The work of mobilisation was carried on with great rapidity at Portsmouth and Chatham on Wednesday, and the ships commissioned at Portsmouth put to sea in the afternoon. The gunboats which hoisted the pennant at Chatham arrived at Sheerness in the evening. The first-class gunboat Onyx had to put back into Sheerness harbour before she could begin her trial on account of a serious leak in her foremost starboard boiler. The trial of the gunboat Sheldrake was successful, and she left Sheerness on Wednesday night for Berehaven. The cruiser Northampton left in the afternoon for Portland.

The quantity of coal raised in the Southern portion of Russia, including the Donetz and Krivo-rog districts, amounted in round numbers to 2,194,000 tons last year against 2,058,000 tons in 1892; that of iron ore to 636,000 tons against 527,000 tons; and that of manganese ore to 76,000 tons and 29,000 tons respectively. The quantity of pig iron turned out rose from 269,000 tons in 1892 to 324,000 tons last year, the make of railway bars increasing from 112,000 tons to 134,000 tons. On the other hand, iron and steel merchant bars show a diminution, the former from what is put at 61,000 tons in 1892 to 33,000 tons in 1893, and the latter from 30,000 to 28,000 tons respectively.

The line of mains with service reservoir, required to enable the Darton Local Board to use water obtained from the well belonging to the Penistone Local Board, is now completed. The distance from the well to the reservoir is between nine and ten miles, and the pressure on the mains equals 425ft. head. The works are now being used. The two contracts for iron pipes and general work amounted to £3000 17s. 6d. and £2150 15s. respectively, or a total of £5151 12s. 6d. The actual cost of the works after adding extras, and making deductions, has been £2707 15s. 1d. and £2226 13s. 6d., or a total of £4934 8s. 7d. The works have therefore been carried out for £217 3s. 11d. less than the total contract amounts, and below the engineer's estimate.

A new fuel gas-making process is in operation at Canisteo, N.Y., by which an excellent gas for heating purposes is distributed to consumers at 25 cents per 1000ft. The process of manufacture is apparently a combined coal gas and water gas process, and the secret of the low price is that the company has to meet natural gas competition. For lighting, the gas is rather poor, though better than natural gas. In the Welsbach burner, however, it gives excellent results. In gas engines it can be used with advantage, and a 10-horse power engine is said to run with it at a total cost of less than 50 cents per day of ten hours. We read in *Engineering News* that the Canisteo Electric and Fuel Gas Company, which owns and operates the plant, is soon to begin laying mains in Hornellsville to supply gas to that place.

The aggregate of shipping passing through the port of Liverpool in the last year was 9,960,000 tons, being an increase on the previous year of 492,363 tons. The total receipts for the year were £1,128,114, or an increase of £40,231. The report for the year ended on June 30th, 1893, had shown diminished trade, but the excess in the year just closed very much more than recovered the lost ground. The dock board are providing docks capable of accommodating the largest vessels afloat or likely to be afloat—vessels of 700ft. length, with proportionate depth and beam. With respect to the bar, they have already removed, by the help of their monster dredgers, something like seven millions tons of sand, and the result has been to greatly diminish the delays of the very largest steamships at the mouth of the river, while other vessels may now be said to experience no difficulties. It is also expected that early next year a new dock, capable of accommodating vessels even larger than the Campania and Lucania, will be ready for use. Judging from these facts, the conditions and prospects of Liverpool trade appear to be in a much more satisfactory way than was generally expected.

The Admiralty, according to the *Times*, have issued an important regulation with reference to interests in patents or inventions. After reciting the terms of section 27 of the Patents, Designs, and Trade Marks Act, 1883, stating that a patent shall have the like effect as against her Majesty, her heirs, and successors as it has against a subject, the new article notifies that all officers or subordinates who hold staff appointments, or who may be now or hereafter employed in any administrative, instructional, manufacturing, or experimental department under their Lordships, or appointed to any ship for service, are to understand that one of the conditions subject to which they hold such appointment or employment is that they shall not take out a patent, nor seek for provisional protection for an invention, without first obtaining the approval of the Admiralty. Each application must contain a general description of the invention for which protection is desired. Should permission be granted it will be subject to the following conditious, from which there will be no appeal:—(*a*) That if it be at any time desired by the Admiralty the patent shall be absolutely assigned to the Secretary of State for War on such terms as the Admiralty may decide upon, after full consideration of all the circumstances of the case; (*b*) that the invention may be used by or for her Majesty's service, and that the terms of payment, if any, shall be decided by the Admiralty; (*c*) in settling terms either for assignment or use regard will be had by the Admiralty to any facilities in originating, working out, and perfecting the invention which the inventor may have enjoyed by reason of his official position, and all payments will be subject to the approval of the Treasury.

# LETTERS TO THE EDITOR.

*(We do not hold ourselves responsible for the opinions of our correspondents.)*

## STRESSES IN A CRANE HOOK.

SIR,—In reply to a correspondent, possibly this will solve his difficulties. Let $\gamma\ \gamma$, Fig. 1, be the vertical straight line through the points of suspension of the hook, and of the load $w$, E F P F the line through the centres of the horizontal sections of the hook, and let P be any point on this line at a distance $x$ from $\gamma\ \gamma$.

Imagine two equal and opposite forces, each equal to $w$, applied at P. These, with the original load $w$, make up (1) a couple of moment $w\,x$, and (2) a force $w$; producing on the area A B H, Fig. 2, (1) a stress $p$, varying from $\frac{w\,x}{z}$ (tensile) at A, to $\frac{w\,x}{z}$ (compressive) at B; where $z$ is the modulus of the section, and (2) a uniform stress (tensile) $\frac{w}{a}$, where $a$ is the area of the section. These two combine in producing stresses whose maximum values are $\frac{w\,x}{z} + \frac{w}{a}$ (tensile) at A, and $\frac{w\,x}{z} - \frac{w}{a}$ (compressive) at B.

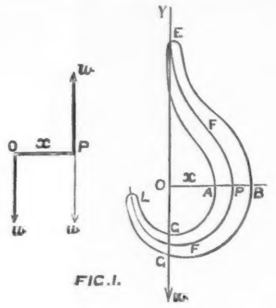

FIG. 1.

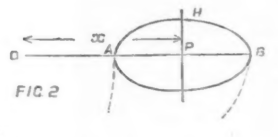

FIG. 2

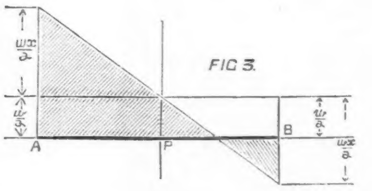

FIG. 3.

The stress diagram for the section A H B is shown in Fig. 3.

The stress therefore is greatest on the line E A G L in Fig. 1. At G, $x = o$, and the stress is $\frac{w}{a}$, where $a$ is the area of the section through G G, and if the hook fails there, assuming there is no flaw in the material, and that it is equally strong under tension and shear, then must $\frac{w}{a_1}$ be greater than $\frac{w\,x}{z} + \frac{w}{a}$,

Or,

$$\frac{1}{a_1} > \frac{x}{z} + \frac{1}{a}.$$

Since the stress along the line E A G $= w\left(\frac{x}{z} + \frac{1}{a}\right)$, it depends on the moment of inertia of each horizontal section, as well as on $x$; it is therefore impossible to give a general diagram for it. Since the bending moment $= w\,x$, the B.M. diagram is evidently the line E F P L, with the straight line $\gamma\ \gamma$ as base.

## CARNOT AND MODERN HEAT.

SIR,—Just a line before going abroad to say that I fear I cannot help Mr. Oldknow much towards an acquaintance with entropy until he feels clearer about the meaning of more ordinary terms. He asks what I mean by energy, heat, and temperature, and whether I do not confuse the two last together. I can only say I hope not; and that I use all these terms in their ordinary signification. He asks me to explain in a few words the meaning of entropy, and asks if it is not "loss of power to do work." He evidently thinks that people are unnecessarily wordy about something that is really very simple, but I fear he must continue to think so, until he devotes some little time and study to the subject. If energy is power to do work, and for ordinary rough purposes this definition serves well enough, then clearly "loss of power to do work" is loss of energy. It would be ridiculous to invent a fresh phrase to express this childishly easy thing. [I perceive of course that the last word of his query (2) is misprinted.]

One of his questions is definite, and can be answered, viz., what is the change in the value of the entropy of a gas when it receives heat at constant temperature? I answer, the number of heat-units received divided by the number of degrees of the gas above absolute zero.

I would willingly help Mr. Oldknow, or anyone wanting to learn, as far as possible; and perhaps he would carefully and slowly read and analyse the first or easy half of Maxwell's little book on heat, wherein every word is carefully weighed, and every sentence after scrutiny becomes luminously clear. There are so many text-books which are worthy of no more than skimming, that a really precise elementary work like Maxwell's "Heat," or a more advanced one of the same high standard, like Rayleigh's "Sound," is liable not to get its proper meed of careful and reverent study. As to Mr. Bryan Donkin's kind offer of help, I shall very likely be glad to take advantage of it if I continue my articles, as I hope to do, with the theory of the steam engine, somewhere about next October.

OLIVER J. LODGE.

July 14th.

SIR,—I have to apologise to Professor Alexander for not giving him his due title. At the time I wrote the letters, I was not aware of his academic status. I do not fully understand the points at issue between himself and Dr. Lodge, but think I am right in concluding that Professor Alexander admits that he has failed to prove that the scale of an air thermometer graduated with equal intervals, whether the air is subjected to constant pressure or is kept at constant volume, corresponds with Thomson's absolute scale.

What does Professor Alexander mean by saying that two things, very different in kind, may be numerically equal? Does he mean, for instance, that 2 lb. of cherries are numerically equal to 2 lb. of beef? That may be so, but he cannot equate 2 lb. of cherries to 2 lb. of beef, or a number of foot-pounds to the differential coefficient of a pressure, or the difference between a number of foot-pounds and a number of pounds of pressure to a volume, or a number of pounds of pressure to a volume. The illustration he has chosen is very infelicitous, since all the members of the equations cited are of the same dimensions.

Neither Professor Rankine nor Professor Alexander has made a mistake in first obtaining general expressions for the laws, and then deducing particular forms. The mistake they have made lies in the fact that they have not arrived at true general expressions for the laws. I have demonstrated in my work on the efficiency of water-wheels, that Rankine's general equation for the value of the impulse exerted by a jet of water against a vane is utterly wrong, and that only one particular solution can be deduced from it, viz., that of the case of a jet striking a flat vane normally, and that this particular solution can be obtained from the general equation, simply because it is unaffected by the erroneous assumption on which the general solution is based, viz., that the relative velocity after impact is equal to the relative velocity before impact. I am obliged to Professor Alexander for giving me his definition of the meanings of the symbols M and N. Mr. Mansel's definition of M, that it is a number of thermal units of latent heat, admits of a different interpretation. In a letter under the title of "Latent Heat of Steam," with which, however, the contents of the letter have nothing to do, "Student" states that M is the latent heat of dilatation. For the purpose of the present discussion we will assume that all three definitions mean the same thing, and agree with Professor Alexander's definition, so that we have—

M = heat absorbed per unit of increase of volume by a unit of mass of air, whose temperature remains constant when it is expanding.

Now the heat absorbed during isothermal expansion, when the volume is increased by unity, is equal to the heat emitted during isothermal compression, when the volume is decreased by unity. If, then, $v_1$ represents the volume of unit of mass of air at temperature $t_1$ and pressure $p_1$, we shall have

$$M = p_1\,v_1 \log. \frac{v_1 + 1}{v_1}$$

since the product of the volume multiplied by the pressure is constant, so long as the temperature remains constant. For any other pressures and temperatures $p\ t$ the volume is by the law of Boyle and Marriotte equal to $\frac{p_1\,v_1\,t}{p\,t_1}$ and we get for the values $p\ t\ v$

$$M = \frac{p_1\,v_1\,t}{t_1} \log. \frac{p_1\,v_1\,t + p\,t_1}{p_1\,v_1\,t}$$

Not only is therefore M, but also its differential coefficient with respect to $t$, equal to a number of foot-pounds. If the general equation is true, therefore, in the case of air, for which N is constant, we have J equal to the differential coefficient of a pressure divided by a number of foot-pounds. Is Professor Alexander satisfied that his particular solution is true? If this particular solution is not true, the general equation from which it is derived cannot be true.

What justification can Professor Alexander bring forward for insinuating that I have ever professed to be ignorant of mathematics? The acknowledgment that I know very little of Thomson's writings is neither a profession of ignorance of mathematics, nor an acknowledgment that I do not thoroughly understand *fin de siècle* thermodynamics. The nature of the information I have obtained from a slight study of Thomson's writings on heat has been fully expounded in your own correspondence columns and those of the *Electrical Review*.

"Student" should not forget that it is the *rôle* of a student to learn, not to attempt to teach. I wonder whether he ever asks himself the question, Do I understand what I read and write? He states that the first law of thermodynamics gives us

$$J\,dQ = dE + dW \quad . \quad . \quad . \quad . \quad . \quad . \quad (1)$$

where $d\,Q$ = quantity of heat received by the body $d\,E$ = internal work done, and $d\,W$ = external work done. In my criticism of part of Dr. Lodge's articles, I demonstrated that the second law of thermodynamics is utterly erroneous. Dr. Lodge, in his review of the reviewer, did not attempt to find any flaw in my demonstration, and I am therefore justified in concluding that he was unable to do so. The first law of thermodynamics is simply the law of the convertibility of heat and work. How does "Student" measure quantities of heat except by quantities of work—by a number of foot-pounds for instance? If "Student" measures quantities of heat in this way, equation (1) states that the product of a number of foot-pounds multiplied by a number of foot-pounds is equal to the sum of two numbers of foot-pounds. The whole Clausian system is, in fact, as I stated at the outset, simply a confused jumble of the two theories of heat. Equation (1) is not true either in accordance with Carnot's theory of heat, or with the theory of the convertibility of heat and work. If "Student" will eliminate the factor J from equation (1), the resulting equation will be true, if heat and work are convertible.

If "Student" will compare the closing paragraph of his own letter with the opening paragraphs of Professor Alexander's letter, his spirit cannot fail to feel a salutary chastening influence.

July 9th. WILLIAM DONALDSON.

SIR,—Mr. Oldknow has very little chance of further enlightenment. Dr. Lodge has obviously told all he knows about entropy to your readers. It is not his fault if he is not clear, it is the fault of the subject.

Entropy is derived from two Greek words, signifying "within" and "nourishment." It is the invention of Clausius, and would not have been heard of in this country if the late Walter Browne had not done Clausius into English. There are not at this moment half a-dozen engineers in Great Britain who know what the word is intended to mean. I believe that I am one of them; Mr. MacFarlane Gray is another, the celebrated Theta Phi diagram being a species of graphic representation of entropy. The said diagram is known to the profane as the "Tater Pie" diagram.

Entropy is a negation, it implies the incapacity of something. Let us suppose, for example, that we have a certain quantity of a gas which contains 33,000 foot-pounds of energy. How much of this cannot possibly be utilised? In other words what is the entropy of the gas? Now, the available energy of a gas, other things being equal, varies as its temperature. Divide the foot-pounds by the absolute temperature and you have the entropy. Let the temperature be 760 Fah., then the entropy is 43·4, and so on. When the temperature is lowest the entropy is highest. It is at a maximum at absolute zero.

The whole affair is of no practical value whatever. It is a species of algebraic abstraction of the sort dear to the German mind. It possesses the same interest as some of Professor De Morgan's speculations on a fourth dimension.

X.

Westminster, July 17th.

## THE MECHANICAL EQUIVALENT OF A HEAT UNIT.

SIR,—As it seems to me to be so singular that all your correspondents should be ignorant of the results of the latest researches in that direction, I venture to present the full paragraph written by Commodore Isherwood, U.S.N., in his report made to the United States Navy Department in 1883, regarding his experiments on the Herreshoff steamer Siesta:—

"The mechanical equivalent of 1 deg. Fah. unit of heat is habitually—but erroneously—taken at 772 foot-pounds, as given by Joule; but the later experimental researches of H. Tresca and C. Laboulaye, to determine the true mechanical equivalent of one calorie—endorsed by Regnault, Piobert, Combes, Bertrand, and Morin—a Commission, appointed by the French Academy to investigate and report upon the subject, give 433 kilogrammetres as the mechanical equivalent of one calorie, which is 789·2385 foot-pounds for one Fah. unit of heat." (*Comptes Rendus* of February 13th, 1865, page 326.) "In reaching this final determination by experiments on air, the experimenters took into consideration every possible correction, and used the best methods which the combined science of the time could devise. The apparatus furnished by the French Government was on a large scale, and as perfect in its design and adjustment as mechanical skill could achieve."

WILLIAM H. HARRISON.

Braintree, Mass., July 5th.

## OIL ENGINE TRIALS AT CAMBRIDGE.

SIR,—The figures of the results of trials as given in your issue of July 6th are, in some instances, so different to what persons engaged in oil engine experiments and construction might expect, that I am tempted to ask if the figures given are correct.

Take No. 1 engine—the Britannia Company. The oil used at full power and at half load is practically the same, when engine friction is taken into account the half load trial is much better than the full load, a result which none of the other engines show, and is hitherto contrary to experience. This engine and Messrs. Crossley's are of the same, type, *i.e.*, using lamps always burning to heat the vaporiser; yet contrary to the result obtained with the Britannia Company's engine, the Crossley engine uses ·5 lb. oil more at half power than at full power. It seems impossible that both these results are correct.

The brake horse-power of the Crossley engine should, I think—from the figures given—read 7·09, not 7·3; if the former is the correct reading the oil used would be ·844 lb., not ·82 lb. The so called half loads seem to vary considerably, from just over half load in one case to two-thirds load with another.

I cannot agree with you that the re-lighting of a starting lamp during a run is of little moment. If the engine is used for electric lighting, and, as several engines often are, is left for two or three hours without the attendant going near them, there is nothing to prevent the engine stopping if half or more lamps are switched off. In future trials I should suggest that a trial be made by running the engines for four or five hours without the men in charge being allowed to touch the engines after they are fairly started. This would plainly show how much attention any engine would require.

JOHN HENRY KNIGHT.

Barfield, Farnham, July 14th.

[Mr. Knight is correct in his observation that the different engines gave apparently very discordant figures, but he has not noticed that they ran in very different ways, varying from satisfactory running to different stages of badness, and even stoppage. The oil used includes that which was wastefully used as well as that which was consumed in proper running. An engine which would not govern well on full load, and lost oil from this cause, need not govern more unsatisfactorily on half load, and the full load consumption would then come out higher proportionately. The 7·3-horse power is a misprint for 7·03, which gives 0·82 lb. per brake horse-power. The 7·03 is, however, an incorrect transfer, and the suggested 0·844 would be wrong. The remark to which Mr. Knight refers regarding the use of a fan and lamp during a run must be taken as relating to an agricultural engine. There would no doubt be very considerable objection to such a requirement for electric lighting work, especially on a small scale, when the attendant may find it necessary to be in attendance on other things just when the relighting of a starting lamp might be required.—ED. E.]

## INDIAN RAILWAY CONTRACTS.

SIR,—Your correspondent "An Indian Engineer" does well in drawing attention to this important subject. Surely no useful purpose can be served by drawing the trade out of this country and the Indian markets—yet such appears to be now the misguided policy of our rulers.

Trade is bad enough in both countries, without giving out contracts to foreign countries for work which in many instances could be better and more economically executed in our own; even if this were not the case, it would still be unwise policy to favour foreign competition, as against our own interests and those of our colonies.

With the concluding portion of the letter I also entirely agree, for it is a startling fact that the confidence of the natives of India in the honesty of our administration is being shaken in a great measure by the policy we are pursuing.

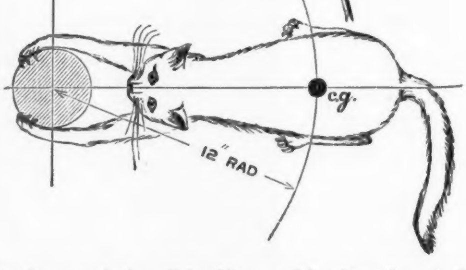
The depreciation of the rupee—more especially as affecting the cotton industry—has already resulted in a marked falling off of our export trade with India, China, and Japan, and is inflicting great hardships upon the natives of India in their dealings with the merchants of this country. Seeing how matters stand, is it not time the Government devised some scheme for raising the value of the rupee, based on the proposals of Indian and home experts, instead of waiting for Dr. Ardenht and other continental financiers to solve the problem, and obtain that credit which should rightly belong to this country, whose interests are most at stake?

AN EX-INDIAN OFFICIAL.

July 18th.

## THE MIDLAND CAT.

SIR,—According to one of the newspapers, upon the arrival of a Midland express at Kettering, a day or two ago, a cat was discovered sitting on the axle of a carriage, and it must have occupied that position all the journey as the train did not stop between St. Pancras and Kettering, a distance of 72 miles. Supposing this paragraph is not the work of some broad-gauge story-teller, and taking the diameter of the carriage wheels at 3ft. 6in., then the pussy-cat must have performed 34,560 revolutions in one hour and twenty-seven minutes. Only a big, powerful, and very determined 10 lb. cat would tackle a job of this sort. Its centre of gravity would fall about 12in. from the centre of the axle. At a speed of sixty miles an hour, pussy would reel off her 480 revolutions a minute, and the velocity of her c. g. would be 50ft. per second. Let $x$ = strain on cat, then



$$x = \frac{10 \times 50 \times 50}{32 \times 1} = 781 \text{ lb.}$$

or about 7 cwt. thrown upon leading claws when travelling at full speed. This is equal to about 17 tons tensile strain per square inch of claw section. Then, again, the wind resistance would be very considerable when she was passing through the top centres. The sketch represents a cross section through the axle, and shows a plan of the cat. Is there room to swing a cat beneath a railway carriage, and do you think that mortal cat could stand this sort of thing? None of my text-books mention a case like this.

Manchester, July 14th. SCRIBER.

## A VOLUNTEER FLEET.

SIR,—I have been interested by the correspondence proceeding in your columns upon this subject. The difficulties in the way of a volunteer fleet—or indeed of any naval tactics by volunteers—are mainly the expense of outfit, &c., and the uncertainties of the sea, causing inconvenience for return to work at a given time. Men who go volunteering mostly work hard in commercial pursuits as well, and they cannot afford to neglect their business appointments. Some years ago I had the pleasure of inspecting the ship Rainbow, off the Thames Embankment, then under the direction of the Royal Naval Artillery Volunteers. The late Lord Ashley took a great interest in this movement, attending drills, &c. The corps organised a summer or autumn cruise, to learn steam tactics and the handling of big guns.

This is the only naval volunteer movement known to me, and I am not aware if any floating fire-engine is worked and navigated by volunteers. Possibly Mr. J. C. Merryweather, whose thoughtful letter originated this discussion, may be able to tell us what has been done in this direction. If a sympathetic attitude were shown by the Admiralty, and a substantial Government grant assured, no doubt many men would enthusiastically take up naval volunteering, in spite of the drawbacks and difficulties. As things stand, we are in danger of having to man our ships with Lascars and Greeks in the next naval war—after the first week's engagements.

West Hampstead, July 11th. JOHN L. LUCAS.

### TO ADVERTISERS.

SIR,—There will be many, no doubt, who on reading the little grumble by "One of the Applicants" mentally remark, "Yes, that is exactly what I think;" many an anxious day or week would be spared to readers of your valuable paper, some of whom occasionally become applicants for the appointments offered in your paper. I am of the opinion that the case is well put by "One of the Applicants." I unfortunately feel the full force of the complaints he mentions, having written for and fulfilled all conditions demanded in advertisement for two months past, and with one exception have not received the slightest notification as to whether or not the vacancy was filled up, after having enclosed stamped addressed envelopes in many cases. But the above is not the only cause for complaint. For instance, suppose that 25 per cent. of the advertisers should apply to the person named for reference, what would be the ultimate result? Let anyone holding an important position answer. How are we to avoid giving offence to those who are at that moment standing between us and our bread, while the present uncharitable system prevails. For myself, I am beginning to adopt the method of "apply in the first instance to A.," but to any honest advertiser this style must appear a little shady, when at the same time I would far rather they applied to "B.," who, as it happens to be in my case, is a gentleman of high standing, to whom I am almost a stranger, yet he has gone out of his way to act most kindly to me. I feel, Sir, that it is ungrateful to trouble a late employer with a number of inquisitive questions by advertisers, some of whom may, through the medium of a *nom de plume*, or Box No., hide the fact that they are fourth-rate employers. I grant that fourth-rate employers have a right to choose, and ascertain that they have got hold of the best man.

Again, how unpleasant it is to think that one's copies of testimonials, so kindly given and of which we are so justly proud, should be either intentionally or unintentionally lying about the office of advertisers, to fall into the hands of office boys or cleaners even, who clear the office of what is considered rubbish. They are precious to me, and have been sent in good faith for return. I trust this will meet the eyes of some of those who have advertised in your paper lately; they need not go to the expense of writing a single word, but for common decency's sake, send the copies of testimonials back, which will be significant of more things than one.

Deptford, S.E., July 13th. ANOTHER OF THE APPLICANTS.

SIR,—I quite endorse all that your correspondent, "One of the Applicants," has to say in regard to answering an advertisement, and would not only utter my complaint in regard to same, but would ask what is done with the stamps enclosed for gaining a reply. It is bad enough to be out of a situation in these days, and though I fully realise the value of an employer's time, I yet think that having asked that his wants should be supplied, it is his duty to express some degree of courtesy towards those that offer their services, instead of allowing his cupidity to assert itself to such an extent that applicants are compelled to suffer in more senses than one. If it is impossible to answer letters, it is possible to do as your correspondent points out, or to advertise that the appointment is filled, and so relieve minds that are in doubt about looking for another situation.

As regards his last item, it speaks for itself, being nothing but a complete subterfuge to test the conditions of the labour market by taking advantage of the fact that the unemployed often forget the value of their services and experience, in the hope of satisfying the demands of home, family, and other ties.

PERFECTLY DISGUSTED.

London, E., July 17th.

SIR,—Your correspondent, "One of the Applicants," has touched upon a very sore point, and I can fully endorse all he says about the indifference that advertisers for managers, &c., show for the welfare of those they seek to employ, and can also add another complaint of quite as serious a nature, if not more so, viz., the advertising for a manager or superintendent by a company, when they have already fixed upon the man who is to be appointed.

I suppose the only reason for advertising is that the secretary may be able to say to any inquiring shareholder, "We advertised in THE ENGINEER, and Mr. So-and-so's appointment is the result."

Southsea, July 16th. ANOTHER OF THE APPLICANTS.

## THE GOVERNMENT OF INDIA NEW MINING RULES.

THE following are the new rules sanctioned by the Secretary of State. They possess considerable interest for those concerned in mining exploration and the promotion of gold mining companies. We may add, that we have been favoured with the advance copy of the rules by the editor of the *Madras Mail*:—

### EXPLORING LICENSES.

A license to explore land for minerals or mineral oil, called hereinafter an exploring license, will authorise the licensee to search the surface of the land specified in the license for minerals of every description, and for mineral oil; and, subject to such restrictions as the Local Government may from time to time impose, to remove any specimens or samples found by the licensee in or upon such land. The surface of unoccupied and unreserved land which is the property of the Government may be freely searched without a license; but the Government does not object to granting a license to explore, when one is applied for.

Such license shall only be granted with respect to land in which the mines, minerals, or mineral oils are the property of the Government, and—subject to the provisions of any law or rule having the force of law, for the time being in force with reference to such land—shall not authorise the licensee to enter upon any land in the occupation of any person without the consent of the occupier.

Such license shall not authorise the licensee to mine or quarry, but he may be permitted to turn up the surface of unoccupied lands, or, with the consent of the occupier, that of land which the Government has granted for agricultural purposes, reserving only the right to minerals to a depth not exceeding 2ft.

Such license may be granted by such person and under such rules as the Local Government may prescribe.

Every such license shall run for one year, and there shall be paid for each license such fee, not exceeding Rs. 10, as the Local Government may prescribe.

A royalty shall be payable to Government on the value of all precious stones found and removed by an explorer, whether he has taken out a license or not. In the case of licenses such royalty shall be at such rate, not exceeding 30 per cent., as shall be fixed by the license, and in the case of an unlicensed explorer shall be 30 per cent. on the value of the stones removed. Neglect to report the discovery of any such stone within a reasonable time shall involve the forfeiture of the license and of all claim to have an application for a mining or prospecting lease favourably considered.

Such license shall give no exclusive or preferential rights, but in considering rival claims for a prospecting license or mining lease, due regard will be had to operations conducted under cover of an exploring license.

### PROSPECTING LICENSES.

(1) A license to prospect for minerals or mineral oil, called hereinafter a prospecting license, shall confer on the licensee the sole right, subject to the conditions contained in the license, to mine, quarry, bore, dig and search for, win, work, and carry away any mineral or mineral oil specified in the license, and lying or being within, under, or throughout the land specified in the license.

(2) A prospecting license shall only be granted with respect to land in which the mines, minerals, or mineral oils are the property of the Government, and which is comprised in a compact block, the area of which does not exceed the area specified in Schedule A, and the length of which does not exceed four times its breadth.

When any area has been explored, and its value as a field for mining sufficiently ascertained, the Local Government may refuse to grant prospecting licenses and may order such area to be demarcated into blocks, and may, subject to such rules as the Governor-General in Council may from time to time prescribe, sell by public auction or private contract the right to win and carry away minerals in and from all or any of such blocks for such term or terms not exceeding thirty years and subjected to such conditions as it may think fit, and may grant mining leases thereof as provided in rules 18 and 19, as it may think fit:

Provided that no such sale as aforesaid shall be made without the previous sanction of the Secretary of State for India in Council if the estimated value thereof exceeds 12 lakhs of rupees.

(1) No prospecting license shall be granted except to a person approved by the Local Government, and such person shall deposit as security in respect of each license such sum, not being less than Rs. 1000, as the Local Government may determine, or give security to the like amount to the satisfaction of the collector. Subject to such deduction on account of compensation for surface damage or otherwise as the collector may order, the amount of any deposit made under this rule will, should the depositor afterwards become the lessee of any mining lease, be carried to his credit as part of the rents and royalties payable under his lease, and should he decline or fail to obtain any such lease as aforesaid, the amount of deposit will be returned to him.

(2) No prospecting license shall be granted to any company or to any syndicate on behalf of a proposed company without the previous sanction of the Governor-General in Council.

(1) Every application for a prospecting license shall, unless the Local Government shall in any case otherwise direct, be made to the collector of the district in which the land or some part of the land with respect to which the license is required is situate.

(2) Every such application shall contain the following particulars, namely:—(*a*) The name, residence, and profession of the applicant; (*b*) a description as accurate as possible, and illustrated by a rough sketch of the situation, boundaries, and area of the land with respect to which the license is required; and (*c*) a specification of the mineral or minerals for which the applicant desires to prospect.

(3) Every application shall be accompanied by a certificate of approval, signed by a Secretary to the Local Government.

On receipt of any such application the collector shall, as soon as practicable, inquire whether the grant of the license applied for is inexpedient either on the ground that the land described in the application is required for a public purpose, or otherwise.

(1) Should the collector be of opinion that it is not expedient to grant the license, or should he find the license has not been approved by the Local Government, he shall refuse to grant the license, and shall forthwith report the matter through the proper channel to the Local Government, which may pass orders as it may think fit.

(2) Subject to the control of the Local Government, the collector, if he finds that there is no objection to the grant of the license applied for, and if the applicant has been approved by the Local Government, may grant to the applicant a license in such form as may be prescribed, and shall report the matter to the Local Government or such other authority as the Local Government may direct.

No licensee shall, while his license is in force, be granted a prospecting license with respect to any other land which lies within such distance of the land covered by his license as is specified in Schedule A:

Provided that the Local Government may, for special reasons, dispense with or modify this condition.

A register of applications for prospecting licenses shall be kept in English in the collector's office, specifying:—(1) Number of application; (2) date; (3) name and residence of applicant; (4) situation of the land; (5) boundaries; (6) estimated area; (7) date of sanction by the Local Government; (8) date of license; (9) rent and royalty payable; (10) period for which granted.

Every prospecting license shall contain such conditions as may in any particular case seem necessary, and shall in all cases contain the following conditions:—

(i.) The term for which the license shall be granted shall be one year or such shorter terms as the applicant may desire. The license may be renewed by the Collector for a further term not exceeding one year, whenever he is satisfied that the licensee has been prevented from completing his search of the land by any cause other than his own default.

(ii.) A moderate rent not exceeding one rupee per acre shall be paid for the land covered by the license.

(iii.) The licensee shall pay a royalty at a rate not exceeding 30 per cent. of the value on all precious stones won and carried away, and a royalty at rates not less than those specified in Schedule C on all other minerals won and carried away over and above such quantity as the Local Government may allow to be taken free for purposes of experiment.

(iv.) No land in the occupation of any person shall be entered upon without the consent of the occupier, and no trees, standing crops, or other private property shall be cut or in any way injured without the consent of the owner thereof.

(v.) The licensee shall make and pay reasonable satisfaction and compensation for all injury which may be done by him in exercise of the powers granted by the license, and shall indemnify the Government against all claims which may be made by third parties in respect of any such damage or injury.

(vi.) The licensee shall not cut or injure any tree on unoccupied and unreserved land without the permission of the Collector in writing.

(vii.) Neither the licensee nor anyone claiming through or under him shall grant or assign any interest under the license to any person without the previous consent in writing of the Local Government, or to any company without the previous sanction of the Governor-General in Council.

(viii.) In case of any breach on the part of the licensee of any of the five last preceding clauses, the collector may summarily revoke the license, and thereupon all rights conferred thereby or enjoyed thereunder shall cease.

(ix.) The licensee shall, within six months next after the determination of the license, or the date of the abandonment of the undertaking, whichever shall first occur, securely plug any bores and fill up or fence any holes or excavations that he may have made in the land to such extent as the collector may require, and shall to the like extent restore the surface of the land and all buildings thereon which he may have damaged in the course of prospecting. Providing that this clause shall not apply to any land held under a mining lease.

(x.) Should any question or dispute arise regarding the license, or any matter or thing connected herewith, or the powers of the licensee thereunder, or the amount or payment of the rent or royalty made payable thereby, the matter in difference shall be decided by the Local Government, whose decision shall be final.

On or before the determination of his license, the licensee shall have a right, subject to the rules hereinafter contained, and provided that the Local Government is satisfied that the prospecting has been of a *bonâ fide* character:—(*a*) In the case of mineral oil or minerals other than precious stones, to a mining lease in accordance with the terms contained in the rules for mining leases; (*b*) in the case of precious stones, to the first offer of such mining lease—if any—as the Governor-General in Council may think fit to grant.

Such lease may include so much land, whether comprising the whole or a part only of the area for which the prospecting license was granted, as shall not exceed the area specified with respect to mining leases in Schedule A annexed to these rules.

### MINING LEASES.

(1) Every application for the grant of a mining lease, not being a lease of a mine of precious stones, shall be presented to the Collector in whose district the land or some part of the land with respect to which the lease is applied for is situate. The Collector shall forward the application through the proper channel to the Local Government.

(2) No mining lease shall be granted otherwise than with respect to land in which the mines, minerals, or mineral oils are the property of Government, and no lease of a mine of precious stones shall be granted except by the Governor-General in Council.

(3) No mining lease shall be granted to any company or to any syndicate on behalf of a proposed company, without the previous sanction of the Governor-General in Council.

19. Every application for a mining lease shall contain:—

(*a*) The name, residence, and profession of the applicant.

(*b*) The name of the mineral for which the applicant intends to mine.

(*c*) A map of the area over which the proposed lease is to extend.

20. On receipt of any such application the Local Government may, if it considers that the applicant should be granted a mining lease, grant the same in accordance with these rules over such one or more blocks, each not exceeding in extent the area specified in Schedule A annexed to these rules, as the Local Government may think fit.

No such lease shall be executed until it has been approved by the Advocate-General or other legal adviser, if any, appointed for the province.

21. Without the previous sanction of the Governor-General in Council, the length of a block shall not be allowed to exceed four times its breadth, nor shall the same lessee be granted either in the same lease or in separate leases more than one block unless the distance between each two of such blocks is not less than that mentioned in the last column of the said Schedule A.

22. The term for which a mining lease may be granted shall not exceed thirty years, and no covenant for renewal may be inserted in the lease without the sanction of the Governor-General in Council.

23. Every such lease shall contain such conditions and stipulations as the Local Government may in each case consider necessary; but shall in every case contain the following conditions, namely:—

(i.) The lessee shall pay a royalty at the rate specified in the lease, which rate shall not be lower than that fixed for the particular mineral in Schedule C; and if any other mineral shall be discovered, then royalty shall be paid therefore at such rate, not being less than 20 per cent. of the value thereof, as the Local Government may determine, until a mining lease has been obtained in respect of such mineral; but the lessee shall be entitled to require and obtain such lease for the term then unexpired of his original lease upon the terms hereinbefore mentioned in Rule 17.

(ii.) The lessee shall also pay for every year after the first year a fixed yearly dead rent, at a rate not less than that laid down in Schedule B; provided that no lessee shall pay both royalty and dead rent in respect of the same lease, but only such one of them as may be the greater in amount.

(iii.) The lessee shall also pay for all land which he may take up, use, or occupy for the purpose of the mine, a surface rent at the rate specified in Schedule B.

(iv.) The lessee shall make, and pay reasonable satisfaction and compensation for all injury which may be done by him in exercise of the powers granted by the lease, and shall indemnify the Government against all claims which may be made by third parties in respect of any such injury.

(v.) The lessee shall not cut or injure any trees reserved in the lease.

(vi.) Neither the lessee nor any person claiming through or under him shall assign the lease, or underlet the whole or any portion of the premises comprised in such lease, without the previous consent in writing of the Local Government; and no such assignment or under-lease shall be made to a company without the previous sanction of the Governor-General in Council.

(vii.) The lessee shall commence operations within two years from the date of the execution of the lease, and shall thereafter carry them on effectually in a proper, skilful, and mining-like manner, unless prevented by unavoidable cause.

(viii.) The lessee shall keep correct accounts, showing the quantity and particulars of all minerals obtained from the mine and the number of persons employed therein, and also complete plans of the mine, and shall allow any officer authorised by the Local Government in that behalf at any time to examine such accounts and plans, and shall furnish the Local Government with such information and returns in respect of the aforesaid matters as it may prescribe. (Note.—All information and returns obtained or furnished under this clause shall be treated as strictly confidential.)

(ix.) The lessee shall allow any officer authorised by the Local Government in that behalf to enter upon the premises comprised in the lease for the purpose of inspecting the same.

(x.) The lessee shall without delay send to the Collector a report of any accident which may occur at or in the said premises, and also the finding therein of any mineral not specified in the lease.

(xi.) Should the royalty or rent reserved or made payable by the lease be not paid within twenty-eight days next after the date fixed in the lease for the payment of the same, the Local Government may enter upon the said premises and seize and sell any minerals or movable property therein, and, if the royalty or rent cannot be so recovered, may determine the lease and take possession of the premises comprised therein.

(xii.) In case of any breach on the part of the lessee of any covenant contained in lease, the Local Government may determine the lease and take possession of the said premises.

(xiii.) At the end or sooner determination of the lease, the lessee shall deliver up the said premises and all mines—if any—dug therein in a proper state for working.

(xiv.) Should any question or dispute arise regarding the lease, or any matter or thing connected with the mines and minerals leased or the working or non-working thereof, or the amount or payment of the royalty, or rent reserved or made payable by the lease, the matter in difference shall be decided by the Local Government, whose decision thereon shall be final.

### GENERAL PROVISIONS AS TO LICENSES AND LEASES.

24. No license or lease shall authorise the commencement of any exploration, prospecting, or mining in a reserved forest, unless previous notice of such intended commencement shall have been given to the District Forest Officer; and such exploration, prospecting, or mining shall be subject to such conditions as the said officer may prescribe.

## TO CORRESPONDENTS.

**Registered Telegraphic Address, "ENGINEER NEWSPAPER, LONDON."**

*** *In order to avoid trouble and confusion, we find it necessary to inform correspondents that letters of inquiry addressed to the public, and intended for insertion in this column, must in all cases be accompanied by a large envelope legibly directed by the writer to himself, and bearing a penny postage stamp, in order that answers received by us may be forwarded to their destination. No notice can be taken of communications which do not comply with these instructions.*

*** *We cannot undertake to return drawings or manuscripts; we must therefore request correspondents to keep copies.*

*** *All letters intended for insertion in* The Engineer, *or containing questions, should be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever can be taken of anonymous communications.*

C. A. H.—*Nothing is known concerning the resistance at enormous speeds. Water must move astern in order that the ship may go ahead.*

A Student.—*If you can procure a copy of Mr. Willans' paper on "High-speed Engines," read before the Institution of Civil Engineers, you will find in it all the latest useful information.*

F. L. W. (Leeds).—*Numerous articles on narrow-gauge railways have appeared in our pages during the last thirty years. You can no doubt consult the volumes of* The Engineer *at the Public Library in Leeds. To give you references would be of little use, as the earlier numbers of* The Engineer *are out of print.*

### KUNENSKI DYNAMO.

(*To the Editor of The Engineer.*)

Sir,—We shall be obliged if any reader will give us the name of the maker of the Kunenski dynamo. J. G. N.
July 16th.

### STRAW PLAIT WEAVING MACHINES.

(*To the Editor of The Engineer.*)

Sir,—I shall be obliged to any of your readers who can give me the name of the maker of straw plait weaving machines? V. G.
Venezuela, June 25th.

### GAUGE BOARD INDICATORS.

(*To the Editor of The Engineer.*)

Sir,—Would you or some of your kind readers please inform me where I can obtain records of gauge-board indications—variations of levels—of any English river, with one of its tributaries, extending over at least thirty years, and much oblige, Constant Reader.
Wickham Market, July 13th.

### SUBSCRIPTIONS.

The Engineer *can be had, by order, from any newsagent in town or country at the various railway stations; or it can, if preferred, be supplied direct from the office on the following terms (paid in advance):—*

| | |
|---|---|
| *Half-yearly (including double number)* .. .. | £0 14s. 6d. |
| *Yearly (including two double numbers)* .. .. | £1 9s. 0d. |

*If credit occur, an extra charge of two shillings and sixpence per annum will be made.* The Engineer *is registered for transmission abroad.*

*A complete set of* The Engineer *can be had on application.*

*In consequence of the reduction of postage on newspapers to one uniform rate for any destination outside the United Kingdom, Foreign Subscriptions will, until further notice, be received at the rates given below. Foreign Subscribers paying in advance at these rates will receive* The Engineer *weekly and post free. Subscriptions sent by Post-office Order must be accompanied by letter of advice to the Publisher.*

| | |
|---|---|
| Thin Paper Copies— | |
| *Half-yearly* .. | £0 18s. 0d. |
| *Yearly* .. .. | £1 16s. 0d. |
| Thick Paper Copies— | |
| *Half-yearly* .. | £1 0s. 3d. |
| *Yearly* .. .. | £2 0s. 6d. |

Reading Cases.—*The Publisher has in stock reading cases which will hold thirteen copies of* The Engineer. *Price 2s. 6d. each.*

### ADVERTISEMENTS.

*** *The charge for advertisements of four lines and under is three shillings, for every two lines afterwards one shilling and sixpence; odd lines are charged one shilling. The line averages seven words. When an advertisement measures an inch or more, the charge is ten shillings per inch. All single advertisements from the country must be accompanied by a Post-office Order in payment. Alternate Advertisements will be inserted with all practical regularity, but regularity cannot be guaranteed in any such case. All except weekly advertisements are taken subject to this condition.*

*Prices for Displayed Advertisements in "ordinary" and "special" positions will be sent on application.*

**Advertisements cannot be inserted unless delivered before Six o'clock on Thursday evening; and in consequence of the necessity for going to press early with a portion of the edition, ALTERATIONS to standing advertisements should arrive not later than Three o'clock on Wednesday afternoon in each week.**

*Letters relating to Advertisements and the Publishing Department of the paper are to be addressed to the Publisher, Mr. Sydney White; all other letters to be addressed to the Editor of* The Engineer.

## MEETINGS NEXT WEEK.

The Institution of Naval Architects.—Summer meeting at Southampton throughout the week.

# THE ENGINEER.

*JULY* 20, 1894.

### THE CORDITE APPEAL.

The small notice that has been taken in the daily press of the appeal by Nobel's Explosives Company, against the decision given in favour of the defendant, and therefore of the Crown, in the recent cordite case, forms a striking contrast with the space and comment devoted to the original trial. This cannot be ascribed to a conviction that the cause in process of settlement has ceased to be of importance either in its commercial aspects or its national issues, but rather to an impression that in the absence of fresh evidence the prospect of a reversal of the judgment of Mr. Justice Romer must be reckoned remote. That the conclusion is not altogether foregone is due to the ingenuity of the plaintiff's leader, Mr. Fletcher Moulton, Q.C., who has marshalled his arguments anew in a form adapted for supporting the plaintiff's claim of infringement, on lines more tenable, if less inclusive, than those upon which his former attack was conducted. The presentment of a case on appeal necessarily differs in some respects from that best fitted for its earlier stage, when each piece of evidence is delivered by the actual witness responsible therefor. Then, the manner as well as the matter of the witness is a factor of moment, whereas, on appeal, the matter alone is available, and its utilisation depends absolutely on the skill of counsel. It follows naturally from this that the Court assumes a more active *rôle* than that proper to the first hearing of the case, and plays the part of *advocatus diaboli* for each side in turn. In the present instance, a tribunal composed of Lord Esher, Lord Justice Kay, and Lord Justice A. L. Smith, is not to be expected to allow disputable points to pass without expression of opinion, and thus the aspect presented by many of the controversial matters in the case, to intellects legally but not technically trained, becomes clearer than was previously possible. The interpolations by the Court which figure between brackets in ordinary law reports, give but an inkling of the mental fencing between judges and counsel, which saved the appeal from a charge of dulness that could not be readily refuted on other grounds.

The course of Mr. Moulton's argument on appeal was similar to that taken in the trial, and included the now-familiar distinction between a propulsive and a blasting explosive. We must confess to a pleasant sense of relief when Lord Esher intimated his sense of satiety with the famous "pith and marrow" phrase, which did duty to an extent fully equivalent to its merits in the trial; and we may, perhaps, be permitted to hope that it has now been decently and finally interred. Bereft of the phrase, Mr. Moulton nevertheless stuck gallantly to the point which it was intended to emphasise, viz., that Nobel's patent being a pioneer patent, the precise limit of the claims pegged out must not be enforced over rigidly. This is exactly the rock upon which the plaintiffs' case previously split. The whole spirit of English law is opposed to special interpretation to fit the moral needs of a given case, and is indeed in that respect in curious contrast with national character, which constantly achieves rough but real justice, devoid of rule. The constant legal suspicion that an attempt is being made to patent an idea, when some latitude is asked for in the interpretation of a specification, was never wholly dormant at this stage of the procedure, and Mr. Moulton had perforce hastily to disclaim so subversive an intention. A somewhat better point, and one which opens up enticing vistas of casuistry, was made in the statement that admitting the plaintiff's patent to be restricted in claim to the use of nitro-cellulose soluble in ether-alcohol, it followed that as the highest commercial nitrated cellulose containing at least 10 per cent. of soluble nitro-cellulose in every 100 lb. of cordite, about 10 lb. were absolutely and indisputably ballistite protected by previous patent. Seeing that by the ordinary method of preparation, cellulose cannot be so completely nitrated as to be wholly insoluble in ether-alcohol, the contention that the soluble fraction cannot be used to make cordite without infringing the ballistite patent will, if sustained, bring the manufacture of the former explosive to a deadlock. The pound of flesh may be cut, but no blood must be spilt in the cutting. Cordite may be made, but no ballistite must be prepared simultaneously. The adjustment of royalties under these conditions would probably be a task of some intricacy. The argument of a case of the first importance on appeal would be sadly incomplete without the use of copious excerpts from the evidence given at the trial, and Mr. Moulton did not flinch from embarking upon what proved to be a tumultuous sea, difficult of navigation. Possibly the absence of the impression created by the suavity or authority of the plaintiff's experts may have been the cause, but in any case the effect was sufficiently definite, Lord Esher recommending Mr. Moulton to throw his witnesses over like so many Jonahs, if he could not get them to agree passably. The incident would be trivial were it not at once an outcome and an instance of the incurable distrust of expert evidence entertained by many of our judges. The experts are not free from responsibility, but they are blameless in comparison with the system which makes such a state of things possible. Can anyone suppose that if the scientific and technical points in dispute—apart from the legal question of validity of patent—had been referred by the court to a small committee of chemists, absolutely unconcerned with the success of either side, that there would have been the least difficulty in obtaining so clear an expression of opinion that all future argument would have been automatically confined to the discussion of the legal force of a few ascertained facts?

The method by which such a conclusion could be reached would be as simple and effective as the present machinery of summoning advocates in the guise of witnesses, examining and cross-examining them, and using their evidence to demonstrate a single view, and to obscure all others, is cumbrous and wasteful. In listening to a technical trial such as the cordite action, even one familiar with the facts and principles under debate is conscious of a feeling of oppression and warping of judgment in the confused mass of irrelevant opinion interwoven with the simplest issues. Granting this, it is obvious that to expect the Court, to which much is novel and barely intelligible, to sift the essential from the accidental, and to discriminate between matters axiomatic in an art or a science and opinion peculiar to the holder and by him adopted *ad hoc*, is to make a demand that can be met by no human intellect, however keen. The conservatism of the law is proverbial, but it is not proof against the breeches-pocket argument. A crowded profession and a stationary amount of work are not causes of incurious content. Commercial and technical cases are falling more and more into the hands of the arbitrator, who in the best instances is himself conversant with the subject in dispute, and in the bulk of disputes where the cost of settlement is of importance his decision will be increasingly preferred to that of a purely legal tribunal. The appeal in this case has confirmed the decision of Mr. Justice Romer, namely, that there has been no infringement of Noble's patent by the Government.

### ENGINEERING AS A PROFESSION.

The correspondence under the above heading which commenced in our columns some weeks ago seems to be drawing to a close; and we regret to find that, instead of a discussion which might have led to results of some importance, we have had mainly an expression of grievances mingled with a certain amount of contempt for our profession. But there have been two sides to the question, and two parties looking at it from different standpoints; and if we could succeed in drawing a happy medium between the two, some useful work would have been done. The two sides to the question are the professional and the trade. The two parties muster, on the one side under "Pater," and on the other, let us say, "Denarius." Of the different faces presented by the question, the one may be dismissed at once—engineering as a trade has no place in a discussion on engineering as a profession. There are many parents filled with ambitious desires for the future of their sons, and anxious to assume a dignity not inferior to that of a lawyer, doctor, or clergyman; they wish them to become professional men in contradistinction to tradesmen. To them, indeed, it must fairly be confessed engineering does not open a wide and hopeful prospect. The number of professional engineers is comparatively small, and those who can be classed amongst the fully successful are, as a rule, men possessed of a special genius. The most excellent training and the greatest assiduity concerning technical subjects; even the greatest success in the early part of his career does not guarantee to the engineer a sufficient income in later life. For one thing, even professional engineering is always under the influence of trade, and rises and falls with its periods of elevation and depression. The doctor and the lawyer are not so fettered. Ninety per cent. of the population need a doctor's assistance at least twice in their lives, once to bring them into the world and once to send them out of it again; and probably 50 per cent. seek the assistance of a lawyer two or three times during their sojourn here; but the professional engineer—be he ever so able—may spend his life unneeded, and employ his time designing force pumps, or vary the monotony by inventing and taking out patents for improvements which he is not wealthy enough to pursue. It seems that we, too, see the seamy side of engineering as a profession; but there must be a smooth side, both cannot be seamy, and perchance there is a hope yet for the rising technical generation. The title profession is too narrow for engineering—"an employment not mechanical, and requiring some degree of knowledge;" such a definition is totally inapplicable, and either we have no right to employ the word profession, or the meaning needs modification. The work of the engineer must, in its nature, be always more or less mechanical. The title trade is as far wrong on the other side, for it *is* possible to be a successful engineer without either being a professional or a tradesman; there is no adjective in the language which exactly describes the occupation. Our technical colleges would certainly be useless were engineering just what some of our correspondents would make it appear to be—a traffic in machines, a trade not needing as much knowledge as that of a tea dealer, a bare acquaintance with a few technical terms, and sufficient mechanical intelligence to understand comparatively well one's own trade circular. This is not engineering at all, and those pursuing such an occupation should have no right to call themselves engineers. It is certainly to be regretted that the title engineer is not more eclectic. We have suggested before in these columns that good would be done if some of our great institutions would arrogate to themselves and enforce the right to bestow the title of engineer, just as the great medical institutions of the land reserve to themselves the privilege of presenting degrees, and indeed on the Continent some of the great technical colleges alone have the authority to give certain qualifications to their alumni. And again we point out the necessity of narrowing down the title—engineer. The point is surely worthy the consideration of some of the more influential members of our profession.

The attack on our colleges, as we took occasion to remark when writing of this subject before, was not by any means justifiable. The technical schools can no more be expected to make successful engineers out of unpromising youth, than can our universities be called upon to fashion bishops and poet laureates out of their sporting undergraduates. A man's success depends on himself. With prospects the most depressing the able and determined man will rise, whilst with the rosiest outlook the vacillating and inapt one fails. Engineering as a means of livelihood is by no means bad; those who fail in it must look in themselves for the flaw; and to parents we must be allowed to say, however smooth and glossy your sow's ear may seem, do not try to make a silk purse of it; and if a qualification test is needed to distinguish between the genuine and the spurious silk, nothing is in the long run more efficacious and expeditious than a few months in the shops. There is no necessity to send a lad as a premium apprentice to a vast establishment where one pays several hundred pounds for the privilege of walking about the yard and putting the possessive pronoun before a particular vice and tool chest. The smallest country repair shed is sufficient primary test for the mettle of the would-be engineer, and a premium of a few pounds gains an easy entrance. A six months' test is sufficiently long, and though at the end of that time engineering may be discarded, certain very useful lessons will never be forgotten. If some such programme as the following were used, there would, we venture to say, be fewer disappointments in engineering as a profession. From a good school at sixteen to seventeen years of age let the youth enter a little shop for six months, paying only a very small premium, and consequently being made to work; thence, if his taste remains the same, let him go through the course at a technical college, and when he has gained his diploma enter an establishment where good work is done, remain there for three years and qualify himself to receive wages as a first-class improver or as a junior draughtsman in some other works. It is not, we consider, advisable to learn only in one establishment; experience is gained by change. A knowledge of a foreign language or two can be acquired by working in the employment of a continental firm. During the latter part of this course the young engineer will be earning enough to ease substantially the strain on his father's pocket.

### COLONIAL MACHINERY.

We here in England are so accustomed to trained supervision of machinery, and to the comparative freedom from serious accidents which follows, that we cannot readily conceive a condition of things in some of our Colonies altogether the reverse. We were prepared to hear of a good deal of laxity in localities where such trained supervision may be very costly, but certainly the revelations made by a correspondent in a late issue of a colonial contemporary has taken us very much by surprise. We do not propose to give the name of the Colony against the procedure in which this correspondent has made his indictment. It might be invidious to do this, for we expect that the old quotation *ex uno disce omnes* might prove of very general application throughout those of our Colonies wherein the introduction of machinery for industrial purposes has been of recent date. In such of these as have had longer experience, it is no doubt the case that, the evil results having before been felt, the necessity for guarding against further repetition of them has been acknowledged and provided for. In the instance to which we are now referring, it may be as well to quote some of the statements made in the correspondence we have named. After writing as to the faulty design and construction of the buildings in which very costly machinery is housed, the letter proceeds:—"With machinery, matters are even worse, and engines and rollers, sifters and fans, can be heard all over the country knocking themselves to pieces through want of a little trained attention to the bearing surfaces. Heated bearings are common, and thousands of gallons of oil are needlessly wasted in lubricating the machinery in factories—often, too, of oil of the most unsuitable kind. Priming in boilers under the circumstances must be common, and I will be very surprised if we do not hear of boiler explosions over the country with fatal results before long, as the machines get older and weaker."

"On a well-known estate not long ago, with an engine below the power of the work required, the energetic superintendent used *to hang a 56 lb. weight on the safety-valve to increase its power!*" Referring to another case, the letter states that the "whole of the fire bars at the back were melted into a solid mass." He had also known of other instances where "two down-draught siroccos, with all their trays and tea, were being converted into furnaces," and burnt to cinders. The justifiable remark follows:—"How can we expect otherwise when sets of expensive machinery, costing from 60 rupees to 100 rupees per acre, are placed in the hands of superintendents who have had no previous training whatever, and have numerous other duties to perform." Apart from the false economy on the part of proprietors which these publicly-stated allegations against them prove, it may well be asked what are the responsible authorities doing to permit, unchecked, the continuance of a state of things which must, as boilers grow aged and deteriorate, threaten danger to those employed in factories so misconducted. We have ever protested against undue Government interference in the conduct of factories at home; but only because we know that circumstances enforce the employment of trained supervision, and the exercise of constant care, without it. In many of our Colonies, however, the case is altogether different. Changed conditions of agriculture brought about the introduction of a large amount of machinery, and in the one of them to which our quotations apply there are probably now from 100 to 150 steam boilers more or less entrusted to the care of wholly untrained native drivers. Most of these boilers have been introduced within the last ten years or so, and the length of their safe life, under the conditions upon which they have been worked, must be approaching its end. If something be not done, it seems to be probable that the majority of these will ere long in turn put an end to themselves, with perhaps disastrous results.

That some steps should be taken to avert the chances of some such finale must be patent to everyone conversant with the danger of leaving such a powerful agent as steam to the control of unskilled persons. In India the planters have become fully alive to the false economy of such a course, and only recently our own columns have included advertisements for thoroughly competent mechanical engineers to take charge of estate machinery. One would have expected that the owners of estates in our smaller Colonies would have all along realised that the same class of supervision was not only necessary from a humanitarian point of view, but essential to commercial success for themselves. It is high time, if these will not realise this, and act correspondingly, that measures should be adopted by the public authority to ensure safety to those whose lives or limbs may be endangered by the culpable neglect of their employers. Were similar conditions observable in the case of home injuries, we should, far from protesting against Government interference, be the first to call for it. Surely, if individual estate owners cannot afford to provide highly-paid and competent supervision, combined effort might furnish it in sufficient degree to avoid the chance of catastrophe, now only too clearly to be foreseen. Or a system of boiler insurance and its allied periodical inspection might be established by the common consent of all.

The crux of the matter lies in the fact that the time is approaching when the boilers first brought into general use for estate purposes in the Colony under consideration are likely to become fatally weak. The correspondent from whose letter we have quoted foresees the approach of consequent grave danger. The time has therefore arrived when, either by voluntary or enforced effort, this should be guarded against. Probably the day will come when the proprietors of estates will have to realise fully how "penny-wise-and-pound-foolish" their conduct has been. They will find forced upon them an expenditure for renewals largely exceeding in amount the outlay that would have ensured them against it. And what is more, they may yet be called upon to pay, in damages for injuries arising from their neglect, a sum double or treble what it would have cost for a more humane and more economic policy. We are glad to see that the colonial press is doing its part in revealing the state of things that exists. We should be still more glad to know that the Colonial Government has become alive to its own responsibilities in the matter.

### THE PROPOSED CARDIFF HARBOUR TRUST.

The Cardiff Corporation, at a special meeting this week, resolved to pledge the rates of the borough in support of the Harbour Trust project, to the extent at least of the expenses involved in obtaining reports from engineers and accountants as to the value of the properties to be taken over. Whether the credit of the borough should be pledged was the crucial question on which the further progress of the Trust scheme depended. A Harbour Trust sub-committee had presented several reports pointing to the success of other Trusts, notably the Tyne and the Clyde, and the necessity of such a mode of administering the several dock estates of Cardiff, in order to maintain the port in a first-class position among its competitors. The owners of the Bute Dock, Penarth Dock, Barry Dock, of the Glamorganshire Canal also and neighbouring landowners whose property would be required for possible manufactories and warehouses, were all waited upon. The replies were in all cases favourable to the principle of a Harbour Trust provided that terms could be arranged, although Sir W. T. Lewis intimated that Lord Bute would want very cogent reasons to be shown before he would agree to sell his vacant lands; and the Barry directors foresaw a difficulty about dealing with their docks apart from their extensive and increasing railway system. Negotiations, however, were regarded as having reached so satisfactory a stage that it became time for the municipality to decide whether it would, as a next step, approach Lord Bute and other dock and landowners for permission to examine their books, ascertain the value of the estates to be scheduled, and make out a statement of the earnings over an average of the past three years. It is to this step that the Cardiff Council have consented, and more practical *pour-parlers* with the directors of the Bute, Penarth and Barry docks can now proceed. The estimated value of the docks, dock railways, the canal, and land for building sites, is £7,000,000. The proposal at present is to acquire this property for the Trust on a basis of 4 per cent. on earnings, for an average of three years. With the rateable value of the borough as security for the interest, it is believed that there would be no difficulty in raising the capital at 3 per cent., which would leave 1 per cent. to the credit of the municipality; or a portion of the purchase money could be raised by loan, and the remainder be secured on 4 per cent. bonds, redeemable gradually by means of a sinking fund. One reason why the shipping and mercantile community of Cardiff are combined in support of the Trust scheme is, that there is known to be behind it a project for converting the existing approaches to the docks into a great floating harbour. There is a constant demand for increased dock accommodation in Cardiff, and it is held that the resources of the new Bute Dock, for which Parliamentary powers were granted this session, will be found insufficient within five years of its completion. But all the dock accommodation, as fast as it is increased, is absorbed by coal shipments, or the export trade. What is wanted, it is claimed, is provision, and separate provision, for an import trade, larger quay space, and sites for warehouses and mills unhampered by the restrictions of existing leases. By constructing sea walls between the entrance of the present Bute Docks and Penarth Head, across the mouths of the rivers Taff and Ely, a vast expanse of mud banks would be enclosed, in which docks could be made, and warehouses built, to satisfy all possible demands of the port for many years to come.

### COKE INDUSTRY PLANT IN AMERICA.

In connection with the manufacture of coke and the utilisation of bye-products a movement is just now going on in the United States which may have important consequences. It foreshadows the creation on the other side of the Atlantic of a demand for coke-making plant and apparatus adapted to the recovery of the bye-products. The Technological Department of the American Geological Survey has sent over to Europe specialists armed with governmental powers of inquiry to report upon the whole subject of bye-product coke manufacture. The Commission are now in this country, and later on are to visit the Continent. As yet nothing has been done in the States other than on a small experimental scale in the direction of saving the sulphate of ammonia, coal tar, and other bye-products, which are now proving so valuable a source of income to the coke manufacturers and pig iron makers of England and Scotland, Germany, France, Belgium, and some other parts of Europe. The old beehive oven reigns supreme. Now, however, the coke manufacturers and the iron and steel masters seem to have awakened to a knowledge of what they are losing, and the inquiry of the Geological Survey is the result. Investigation is to be made alike into the horizontal and vertical flue systems. The Commission will return home enabled to pronounce definitely which of the two broad lines of construction is likely to be most acceptable to American practice, the relative production of the varied British and Continental systems, and the special merits of each. If, as appears probable, the Commissioners are able to report that a saving in waste products of 4s. per ton on the coke manufactured can be effected, and that no material deterioration in the quality of the coke for blast furnace purposes ensues, then a great demand should almost at once spring up for ovens built upon the new principle, and for the accompanying plant and machinery for the recovery of the bye-products and converting of the same into ammonia, tar, and other productions of modern chemical and engineering science combined.

### PURE WATER AND ITS ELECTRIC RESISTANCE.

Until recently the purest sample of water that has been physically examined was that obtained by Prof. F. Kohlrausch by distillation in vacuo, and which showed an electric conductivity only one-third of that of water distilled under atmospheric contact. Such low conductivity only endured for a short time, owing to the water taking up foreign matter from the sides of the containing vessel or the electrodes. The distilling apparatus used on that occasion, after standing full of water for nearly ten years, has lately been used by Messrs. Kohlrausch and A. Heydweiller in some new experiments, which have been described in the "Transactions" of the Academy of Sciences at Berlin. The water obtained has, when tested at 18 deg. C., only one-sixth of the conductivity of the former sample; the resistance of one square millimetre at the freezing point being the same as that of a copper conductor of the same section, 25,000,000 miles long, or more than a thousand times the circumference of the earth. The foreign matters contained in this water only amount to a few thousandths of a milligramme in the litre.

## LITERATURE.

*The Naval Annual.* By Lord Brassey. T. Griffin and Co., Portsmouth. 1894.

The "Naval Annual" for 1894, although not containing anything especially startling, keeps up its old reputation and that of its able compiler. The records of the past year—with the single exception of the irreparable loss of H.M.S. Victoria and so many of her gallant crew—afford, perhaps, less subject matter than usual of a remarkable character; nevertheless they contain much that is both interesting and instructive. For the first time, past history, with all its valuable lessons, has been introduced with the view of emphasising certain features of our naval position; and an estimate has been given of the empire's resources for warship building above and beyond those afforded by the Royal dockyards of the United Kingdom. The important questions of "Moderate Dimensions," "Convoy," and "Our Strategic Position in the Mediterranean," are likewise discussed with considerable ability.

As usual, Lord Brassey's own particular and most interesting chapter comes at the end of the volume. But, although his absence in India must have made it exceptionally difficult for him to work up arrears on his return, and to prepare a paper in time for publication, it is, nevertheless, satisfactory to observe that—where quoting *in extenso* the lists of vessels compiled by Lord George Hamilton, showing our urgent naval requirements at the commencement of the current year—the author of the "Naval Annual" appears fully alive to the necessity for keeping the naval strength of the British Empire abreast of that line towards which some of the other Great Powers of Europe are pushing forward so vigorously. Two capital schedules are given, exhibiting the comparative strengths of the fleets of the world built and building, though we must caution our readers against accepting them verbatim, as they are founded upon classification. The impossibility of absolute classification is apparent when we consider—as an illustration—that the Benbow and Centurion, both of approximately similar displacements, have a main armament in one case of 111-ton guns, in the other of 29-ton guns! Under these circumstances, how can the two vessels be compared usefully? But we give the tables for so much as they are worth:—

*Armour-clad Battleships.*

| | Great Britain. | France. | Russia. | Germany. | Italy. | United States. | Combinations of two Powers | | | |
|---|---|---|---|---|---|---|---|---|---|---|
| | | | | | | | France—Russia. | France—Germany | France—Italy. | France—U.S. |
| First-class ... ... | 22 | 18 | 10 | 4 | 12 | 4 | 28 | 22 | 30 | 22 |
| Second-class ... | 12 | 13 | 8 | 7 | 4 | — | 21 | 20 | 17 | 13 |
| Third-class ... ... | 20 | 6 | — | 11 | 5 | 2 | 6 | 17 | 11 | 8 |
| Total ... ... | 54 | 37 | 18 | 22 | 21 | 6 | 55 | 59 | 58 | 43 |
| *Armoured and Protected Cruisers.* | | | | | | | | | | |
| First-class ... ... | 22 | 14 | 11 | — | 6 | 3 | 25 | 14 | 20 | 17 |
| Second-class ... | 47 | 25 | 2 | 9 | — | — | 27 | 34 | 25 | 25 |
| Third-class ... ... | 51 | 31 | 3 | 19 | — | — | 34 | 50 | 31 | 31 |
| Total ... ... | 120 | 70 | 16 | 28 | 6 | 3 | 86 | 98 | 76 | 73 |

It will be observed that in battleships we appear to be practically a match for any two European Powers, but, were the obsolete wooden ironclads of France to be eliminated, which is the only reasonable course to pursue, the preponderance would be enormously in favour of the fleets of the British Empire; and it must be borne in mind that the above quoted figures are altogether independent of the seven first-class battleships, six second-class cruisers, and two sloops, to be commenced, or already laid down, in the current financial year. In cruisers we are — comparatively— clearly ahead of our requirements.

Although, however, an inspection of these comparative tables is calculated to inspire confidence as regards our present and prospective positions, the efforts now being made by France and Russia to improve theirs must not be lost sight of. Lord Brassey supplies some interesting totals illustrating this point. The expenditure on new naval construction in France, which stood at £614,460 in 1872-3, amounts for the current year to £3,049,720. That of Russia for shipbuilding in 1894 is £2,255,627. The sum of these two amounts, viz., £5,305,347, must be contrasted with £5,166,110, which is the total available in the United Kingdom for new construction in 1894-95. It will thus be seen that France and Russia combined are pressing us very closely in the laying down of new ships.

Some very convincing arguments from the writings of Admiral Bourgois and Captain Malan are adduced, in order to support the theory that fleets of battleships alone can secure the command of the sea. All the teaching of history appears to be in this sense. When, in the latter years of Louis XIV., and in the reign of Louis XV., fleets of battleships were no longer fitted out, and the efforts of the French by sea were directed solely to privateering, the result was seen in the humiliating conditions accepted in the treaty of Utrecht. Private individuals grew rich by the capture of the merchantmen of the enemy; but the consequences of the disappearance of her fleets from the seas were disastrous to France as a nation. Captain Malan sums up the question as follows:—"On sea as on shore, great results can only be expected by wielding great masses. Upon this conclusion history, too, has set its seal, for the squadron and division warfare of the French navy, seconded though it was by hosts of commerce destroyers, public and private, produced practically no results, had absolutely no effect upon the issue of the war."

We deem, therefore, that the wisdom displayed by our Admiralty authorities in laying down fresh fleets of battleships is not to be called in question.

The narrative of "The Naval Revolt in Brazil," by Mr. W. L. Clowes, is very instructive. Fifty heavy guns, including eighteen 6in. and four 7in. quick-firers, also upwards of one hundred smaller quick-firing and machine guns, were mounted in the insurgent fleet. The chief Peixotist forts were Santa Cruz, with two 10in. Armstrongs and smaller weapons; San Joao, with one 10in. Armstrong; Fort Lage, with three 6in. Whitworths; a work at Nictheroy, with two 32-pounders, &c. As operations went on these were reinforced. Fort Villegagnon, neutral at first, was beneficial to the insurgents. Its thirty-seven heavy Armstrongs and six Whitworth guns would have been a terrible menace to them otherwise, irrespective of its position commanding the channel.

The preponderance of gun power in favour of the fleet under Admiral Mello was, however, counterbalanced by the paucity of sailors and marines. He had, at the outset, only 1500, and all his operations were obviously hampered by his short-handedness; whilst the defences of the Peixotists had 5000 regulars armed with Mannlichers, irrespective of volunteers. The helpless position of the fleet was of course due to the impossibility of occupying places after a landing had been effected.

But an instructive lesson taught by this narrative is one of increased confidence in the modern war vessel as a safe fighting platform. It is true that for the first few weeks the firing was very wild; but practice improved, and the fort gunners learned to aim with precision, whilst with high angle fire they succeeded in dropping many a shell upon the decks of their adversaries. With all this, however, the Javary, an old iron monitor of 3640 tons, with belt and turret plated, was the only ship sunk under fire, and the incident was due to leaks resulting from the working and shaking of her frame with the vibration of her own 10in. Whitworth guns. The details of one action, in which the battleship Aquidaban took part, are interesting. Five projectiles in particular struck the ironclad, amongst others. One heavy one passed through the deck into the admiral's sleeping cabin, and there burst, doing little harm. A 6in. projectile penetrated the starboard side, and exploded another 6in. shell standing in a rack on the battery deck, the latter being ready fused—which it ought *not* to have been. An officer and three men were wounded. Another shell penetrated the admiral's bath room innocuously. A fourth exploded in the coal bunkers on the port side, making holes in the inner wall. A fifth projectile struck the armour shield of the port bow gun without impairing the working of the weapon. Admiral de Mello collected five 6in. projectiles which came on board that day, and set them up as ornaments in his cabin. It is clear, therefore, that wooden battleships do not sink so easily under fire as has been anticipated.

The "Progress of Foreign Navies," by M. E. Weyl, gives particulars of battleships and cruisers building and completing in France, that cannot fail to awaken interest. The armoured protection of the Charlemagne and the St. Louis is afforded by a continuous belt at the water-line, the maximum thickness of which is 15¾in., and above the belt the neighbourhood of the cofferdam is covered with 3¾in. plates. Two armoured decks will be fitted; the first will be of 3½in. steel, and at the level of the upper edge of the water-line belt; the second is 1½in. in thickness, and will join the lower edge of the belt. The space between the two decks will thus form an enormous "caisson," which will be partly filled with coal. Four 11·8in. guns are mounted in closed armoured turrets, forward and aft; and the secondary ten 5½in. quick-firers, and six 4in. quick-firers, are so distributed that six of the former—which are protected by 3in. plates of hardened steel—and four of the latter can be fired simultaneously ahead or astern, independently of the main armament. The principal armament and the turrets can be worked either by hand or electricity. The displacement is only 11,232 tons, 1000 tons less than the Renown; yet upon this smaller displacement an armament of much more powerful character is to be mounted, out of which no less than twelve guns can bear directly ahead or astern against four in the Renown, and the triple screws afford an equal rate of speed to the smaller ship, namely 18 knots.

The cruiser Yoshino, built at Elswick for the Japanese Government, has gone most satisfactorily through her trials. Although of only 4150 tons displacement, the engines developed nearly 15,000 horse-power under forced draught, the largest proportion of horse-power to tonnage in any great cruiser afloat, not excepting the commerce destroyers of the United States. The mean speed was 23·031 knots.

Mr. James R. Thursfield's remarks on the lessons of naval manœuvres of the year 1893 are valuable as usual. It appears to have been demonstrated more completely than ever that "even in default of an active defence adequately organised and skilfully disposed, torpedo boats are very apt to suppress themselves and to attain a very high rate of extinction in the normal course of their attacks on a powerful and vigilant seagoing adversary. The truth seems to be that a torpedo boat ought properly to be regarded not as an independent seagoing unit of naval force, but as a peculiar and very destructive kind of projectile . . . having a considerable liability to be destroyed or intercepted before it attains its mark . . . to say nothing of its very awkward habit of occasionally mistaking a friend for an enemy!"

The paper upon Toulon is accompanied by a sketch map indicating the positions of the great Government dockyard and the private establishment at La Seyne; also the chain of immense heavily-armed forts which command all the approaches, whether by sea or land. The breakwater which separates the outer anchorage, or Grande Rade, from the Petite Rade, is admirably situated to seal the entrances to the latter in time of war. It is honeycombed at either end with torpedo-dischargers, and also provided with destructive batteries of quick-firing guns, to check the admission of the enemy's torpedo-boats. As a completing and repairing station Toulon is, however, very inferior to Portsmouth. Ships after being launched have to be completed at an anchorage afloat, and the expense and labour of transporting all the materials by lighter must be immense.

Mr. Thursfield's remarks upon the foundering of the Victoria are temperate and to the point. He accepts the verdict of the Admiralty minute, which practically lays the blame for the accident upon the failure to close the water-tight doors in time, but shows that, even were only such doors left open as are indispensably so, the interval of time which elapses between the first warning of a disaster and the supreme moment of danger is not sufficient to admit of the necessary action being taken; in other words, that under the existing arrangements for closing water-tight doors, the movement cannot be carried out instantaneously as required. It would appear, therefore, that some more rapid and effectual machinery will have to be applied.

Admiral Colomb feels very strongly as to "our strategic position in the Mediterranean." He thinks that necessity is laid upon us to make every effort to secure and to keep such a command of it in war, as we all admit we must keep of the Channel. But he considers that the great power of quick reinforcement from home is surely a safer policy to pursue than a detachment of force into those waters at all times, which force we are not sure will be ultimately required.

The remarks of a student of naval history upon "moderate dimensions" will find plenty of admirers and detractors. Nevertheless by the light of history, which should be an unfailing guide, he proves unmistakeably that the monstrous battleships with four or five decks and a hundred and thirty guns seldom or never met with success in opposing an equivalent number of seventy-four or eighty-gun ships of the line.

---

*Mountain, Moor, and Loch, Illustrated by Pen and Pencil, on the Route of the West Highland Railway.* London: Joseph Causton and Sons. 1894.

IT is possible that to many of our readers the very existence of the West Highland Railway may be a fact as yet unknown. The line was indeed only recently opened, and the book before us describes the wild, beautiful country through which it passes, hitherto little known, excepting to the few. Starting from Helensburgh, the line takes the tourist on through the softly wooded scenery skirting the shores of Loch Long to Ardlui, at the head of Loch Lomond, thence leaving the lochs behind, through the hill country to Gorton, on the edge of Rannoch Moor, that wild and majestic stretch of table land, strangely impressive in its bleak loneliness to the dwellers in cities, if less strictly beautiful than some of the scenes left behind. Rannoch Moor used to be regarded as an impassable barrier by railway engineers. That the West Highland Railway should have been so constructed as "virtually to float over the moor," may therefore be considered as a considerable achievement in the annals of railway engineering. The moor was deep and cross drained to take off the water, and across the trenches was laid, as at Chat Moss, on the Liverpool and Manchester line, a thick layer of brushwood, as a bedding for the permanent way.

Leaving Rannoch behind, the railway extends itself to Lochaber, which used to be considered "such a far cry," and on to the foot of the mighty Ben Nevis—in all about 144 miles from the starting-point at Helensburgh. It is a land of romance, and the charm of its weird, picturesque beauty is enhanced for the traveller by its association with many of the most stirring episodes in Scottish history, while its romantic and striking natural characteristics have suggested a rich fund of legend and story, with which the author is evidently familiar. His explanation of the reason why a lobster is known in the Highlands as a "Banavie flea" is too good to be lost, and must be quoted:—

> A good many years ago an American was stopping in the Banavie Hotel, and he made himself very obnoxious by his contemptuous remarks on Scottish scenery. "Ben Nevis," he said, "Do you call that a mountain? You should see our mighty Rockies. Loch Linske. Do you call that a lake? You should see our Lake Superior! Rannoch Moor. Do you call that a plain? You should see our Western prairies!" and so he went on to the intense exasperation of the Highland waiter who went and procured a live lobster—for they are caught occasionally in the loch—which he secreted, in requital of the insults, in the American's bed. Hardly had the American gone to sleep when the lobster caught him by the toe with a grasp like a vice. He jumped out of bed with a yell and rang for the Boots. "Boots," he said, solemnly rubbing his toe as he spoke, "you may not have such big mountains and big lakes and big plains here as we have in the States, but you have the most tarnation big fleas I ever experienced."

Altogether, the book forms one of the most attractive guide-books that has lately come under our notice. A glance through its pages will convince those about to visit the regions described that they have a delightful experience before them; while those who cannot hope to do so will find themselves wishing that it were in their power to travel over the ground so pleasantly described by the author, whose graphic word-pictures are admirably supplemented by 230 charming illustrations, reproduced from original drawings executed specially for the work.

## *BOOKS RECEIVED.*

*Theoretical Mechanics: Solids.* By J. Edward Taylor, M.A., B Sc., Lond. London: Longmans, Green, and Company. 1894.

*Concrete: Its Use in Building and the Construction of Concrete Walls, Floors, Roofs, &c.* By Thomas Pitter. Vol. ii. London: B. T. Batsford.

*The Great Eastern Railway Company's Tourist Guide to the Continent.* Edited by Percy Lindley, illustrated. London: 30, Fleet-street, and 61, Regent-street. 1894.

*A Text-book of Ore and Stone Mining.* By C. L. Neve Foster, B.A., D Sc., F.R.S. With frontispiece and 716 illustrations. London: Charles Griffin and Company. 1894.

*Elementary Treatise on Natural Philosophy.* Based on the Traité de Physique of A. Privat Deschanel. By J. D. Everett, M.A., D.C.L., F.R.S. Thirteenth edition. London: Blackie and Son. 1894.

---

LIGHT RAILWAYS IN CÔTES DU NORD, FINISTERE, AND MORBIHAN.—According to a recent Foreign-office report: in Côtes du Nord, the new line from Guingamp to Carhaix was opened in September last. A new line from Guingamp to Paimpol is in course of construction, and will probably be ready for traffic this year. Work on the new line from Loudéac to Carhaix and St. Méen is to be commenced this year. In Finistère the light railway from Brest to Ploudelmezeau was opened for traffic at the end of last July. A similar line, to Llanilis, was opened at the end of last February. Another light railway, from Audierne to Douarnenez, affording direct communication between the former place and Quimper, on the Orleans and Western lines, was opened at the end of last January. The line from Landerneau to Lesneven and Plouéo-sur-Trez, is nearly finished, and will be opened for traffic at an early date. The traffic on the Ploudelmezeau line has already exceeded expectation, and the receipts from the other lines are expected to be equally satisfactory. Short extensions of the Ploudelmezeau line to Portsal, Llanilis line to L'Abervrach, and the Lesneven line, when completed, to Brignognan, on the Channel coast, are in contemplation, and will probably be carried out soon. These narrow gauge lines, constructed on most economical principles, will be of great service to agricultural, fishing, and other industrial interests. Being situated in good districts, they will naturally tend to create traffic, to the benefit of the community and their promoters. Other short departmental lines are projected, and much interest is being shown in the question. Work on the line from Carhaix to Rosporden is being proceeded with. Nothing has been done towards connecting Morlaix Railway Station with the port, the matter being still under consideration. In Morbihan several light railways are being projected. Plans have been prepared, and concessions will shortly be given for lines from Locminé to La Roche-Bernard, *viâ* Vannes, from Lorient to Gourin, *viâ* Plouay, and from Ploermel to Plouay, work on these lines being proceeded with consecutively. Other light lines are in contemplation. The necessity of doubling the line between Rennes and Brest, a distance of 155 miles, is strongly urged by the local agricultural and commercial interests, the line at present consisting of a single track, except two short sections twenty-four miles long between St. Brieuc and Guingamp and Brest and Kerhuon. A second track would not only afford much needed greater accommodation and quicker transit for the products of this part of Brittany, but would also permit a material acceleration of the through passenger traffic not possible under present circumstances. The estimated cost of the work is £480 000, or £3097 per mile.

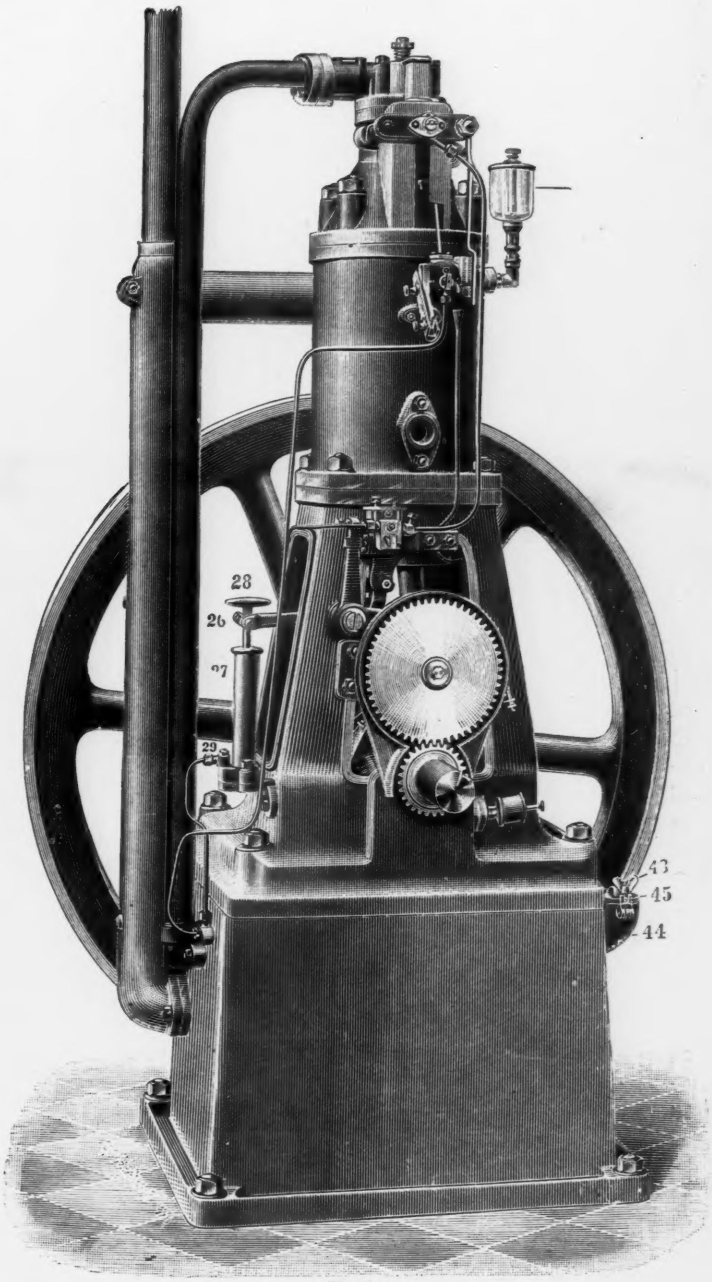

Fig. 3

## OIL ENGINES AT CAMBRIDGE.

There remains one fixed engine which ran in the long duration trials, but of which we have not yet given a description. It is a vertical engine, and belongs to Class 4 of our classification, the vaporiser forming at the same time the means of ignition of the compressed charge. The general arrangement of the vaporiser in connection with the combustion chamber is shown by the annexed diagram section, and the engine is shown by the accompanying engravings.

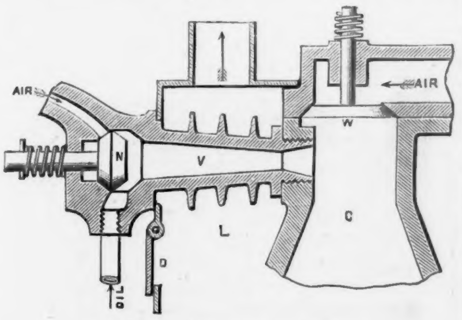

Fig. 1—THE CAPITAINE VAPORISER

The vaporiser V is a small tubular ribbed casting screwed into the side of the combustion chamber C. In our diagram sketch we have much exaggerated its size for clearness. Oil is injected by a supply pump into the space containing the valve N. When the down or suction stroke of the engine takes place, air is drawn in at the main air valve W, and also through the small air inlet at the rear of the valve N, kept normally closed by the spring S. Oil is injected by a feed-pump, and being carried in by the inrushing air, is sprayed into the vaporiser and instantaneously vaporised. It is supposed that the vaporisation is complete before the suction stroke of the piston is completed, so that the vapour is completely cleared of all trace of combustible material. A lamp is placed at L, and access to the flame is obtained by a door at D. The position of the vaporiser and lamp is shown in Figs. 2 and 3. The oil is injected a little before the commencement of the suction stroke of the piston. The lamp which is used for heating the vaporiser and usually kept at work with the engine, though not used in the Cambridge runs, is a simple spray burner, the oil being sent up from a tank in the base, from which it is ejected by a slight air pressure, occasionally renewed by the hand pump at 27, 28, Fig. 3. The base of the engine is partly oil tank and partly exhaust box, so that the oil is somewhat heated by the waste gases. Starting is effected by means of a spirit lamp which heats the petroleum spray burner. To govern the temperature of the vaporiser a small valve is inserted in the oil passage thereto, and the position of this is controlled by the pressure exerted by a piece of iron which rises or falls in temperature with the vaporiser, and by corresponding expansion and contraction affects the position of the oil supply valve. The oil pump is shown at the side of Fig. 2 and in front of Fig. 3. It is worked by an excentric inside the frame as shown. The pump is fitted with a ⊂⊃ distributing valve, and it is filled with glycerine so as to avoid the leakage so usual with petroleum pumps and joints. The pump valve governor is peculiar and ingenious, but could not be described without detail drawings. In Fig. 3 the petroleum inlet valve is shown immediately above the heating lamp, and its position will be recognised by reference to the position marked on Fig. 2.

The engine has hitherto been worked on oils lighter than Russolene, and it was not well prepared for running on the latter, although the length of time that it did run shows that this oil can be used, but possibly it will have to be specially arranged for.

## BRITISH MACHINERY AND TOOLS IN HONDURAS.

According to a recent Foreign-office report, while in general merchandise English products are as eagerly sought after as ever in Honduras, American manufacturers are making the greatest advances in machinery and general ironmongery. Month after month steamer after steamer unloads tons upon tons of machinery at Amapala, the greater part consisting of mining machinery, pumps, saw mills, steam engines and boilers, and wood-working machinery. The greater number of mining enterprises in this country being in the hands of Americans, it is natural that they should prefer machinery from their own country, but it is surprising that English and French mining companies, after erecting English machinery have abandoned it, and substituted for it either complete or partial American "outfits." Price has in no way entered into consideration in these changes, adaptability to the work required, and economy in performing the same, being the only factors. There seems to be a business deficiency on the part of our manufacturers that should be looked into and remedied as soon as possible. The foregoing state of things is beginning to be the case in edged tools. Formerly Honduras artisans were content with almost any kind of axe, chisel, plane or saw, if the price was sufficiently low, but they now demand a better class of tools, and require quality regardless of price. American edged tools are prominent both in quality and temper, but Germany is bidding for a share of this trade with a stubbornness that bids fair to be successful, while our own manufacturers are content to manufacture what gave them good results in the past, forgetting that others with less facilities are striving continually to improve, and are surely advancing to the front in goods until recently exclusively English.

During the last six years trade between Amapala and Germany has enormously increased, owing to two lines of steamers having been established between this coast and Hamburg, *viâ* the Straits of Magellan. As these steamers offer freights lower, and deliver goods direct from wharves in Hamburg without transhipment at the Isthmus of Panama, much merchandise formerly ordered only from England is now bought in Germany. English crockery, iron, and all manufactures of small cost paying high freight are those suffering most from these steamers. According to the latest

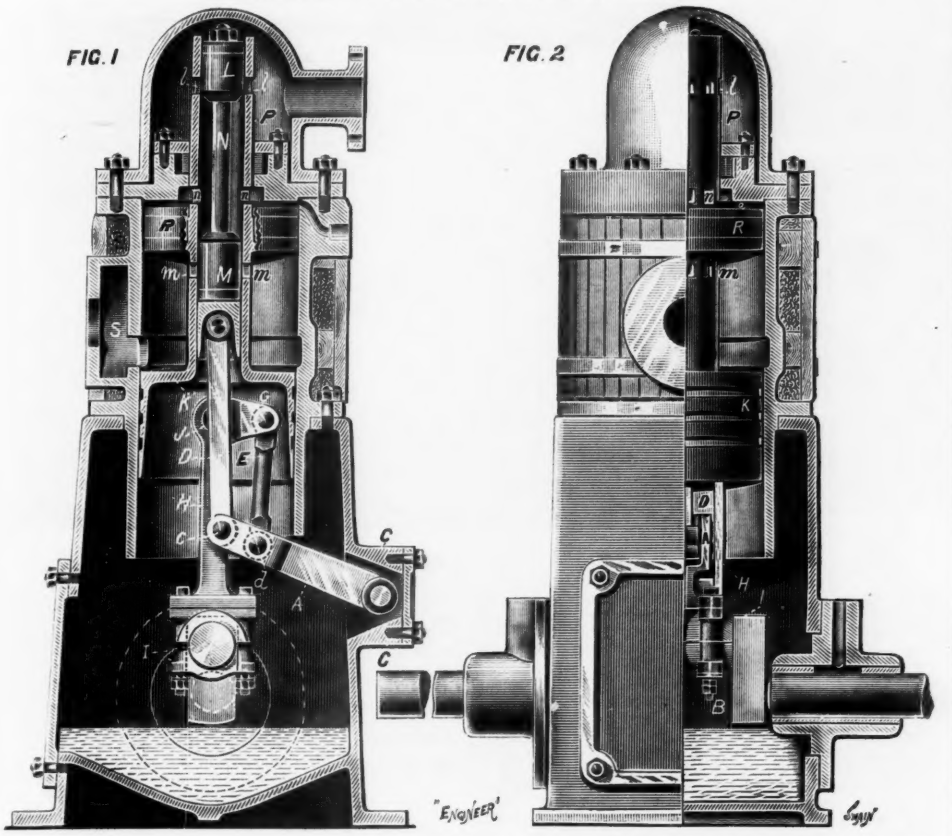
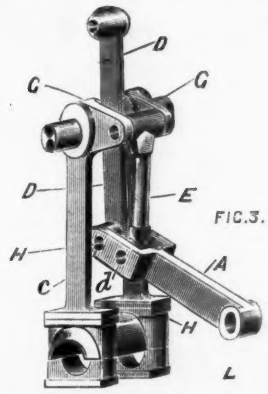
THE BLAIR ENGINEERING CO., PECKHAM, ENGINEERS



available statistics, British imports into Amapala decreased by £26,000, or 35 6 per cent. under the previous year, and in proportion of the whole from 31·8 to 25 per cent., while German imports increased by £11,953, or 115·45 per cent., and in proportion of the whole from 4·9 to 12·5 per cent. It is suggested that a similar line of steamers, established on a paying basis from Liverpool or Manchester, would go far toward protecting many English industries against German energy and enterprise.

## THE BEAUMONT-WALLINGTON HIGH-SPEED ENGINE.

THE engravings above illustrate a new engine of the single-acting description, with central valve contained in a hollow extension of the piston-rod which is actuated by a new radial gear. The latter is also a new departure in this class of engine. This gear gives to the valve a motion which causes a very perfect distribution of steam in the cylinder. During one revolution of the crank there are four distinct movements of the valve: (1) A quick upward movement opening the valve for admission; (2) a quick downward motion performing cut-off; (3) a longer period of comparative slow movement during expansion; (4) another quick movement opening the exhaust port, which remains open till nearly the top of the return stroke, when it closes, forming the steam cushion. On referring to the illustration, it will be seen that the connecting link D is attached to the extremity *c* of a vibrating lever A; an intermediate point *d* in this lever is connected by a link E to a short arm G at right angles to, and forged solid with, the connecting-rod H at the crosshead end.



All the functions of lead, cut-off, expansion, exhaust, and compression are performed thereby in a simple, quick, and accurate manner. In order to show how this is attained, we may suppose the connecting-rod H to be disconnected from the crank pin, and moved from its top position, as shown in the illustration, to the centre of the stroke in a straight line, without swinging the lower end to either side; it is evident that the arm G would move down the same distance as the piston, consequently the intermediate point *d* on the lever A would also travel the same distance, but the extreme point *c* would move a greater distance; the difference of the distance of the travel of these two points *c* and *d* respectively being equal to the lap and lead of the valve. Now, if the connecting-rod be swung to the right until it comes to its proper position in the crank circle, it is evident that the end of the lever G would move upwards, carrying with it the link E, lever A, and the valve link D, together with the valve. The actual movement of the valve relatively with that of piston in half a revolution is therefore equal to the difference between the travels of the points *d* and *c*, together with the motion imparted by means of the arm G. The amount of steam port opening is determined by the length of this arm together with the distance between *d* and *c*, and by varying these any degree of expansion can be obtained. It will be seen that the link D is always in compression and the link E in tension, so that any slight wear in the one is compensated by wear in the other. The gear is therefore self-adjusting.

These engines are made either simple, compound, or triple-expansion, with either one or two cranks. The cranks are of steel and the bearings of phosphor bronze. The crank chamber is closed, as shown in the engravings, and forms a receptacle for the lubricant, in which the crank revolves, as is usual in this class of engine. The engines are made under the patents of Messrs. Beaumont and Wallington by the Blair Engineering Company, Bellenden-road, Peckham, S.E.

## DUCKHAM'S PNEUMATIC GRAIN ELEVATOR AND CONVEYOR.

DURING the ten years ending 1850, the imports of grain into the United Kingdom averaged 1,022,067 tons per annum. During the ten years ending 1890 it averaged 6,157,276 tons per annum. During 1893 the quantity imported was no less than 1,450,000 tons. This increase has undoubtedly been made possible, firstly, by the substitution of grain-carrying steamers of 2000 to 4000 tons and more capacity for the old-time sailing vessels of 300 to 400 tons; and secondly, by the employment of various mechanical appliances for discharging the cargoes and for distributing the imported grain.

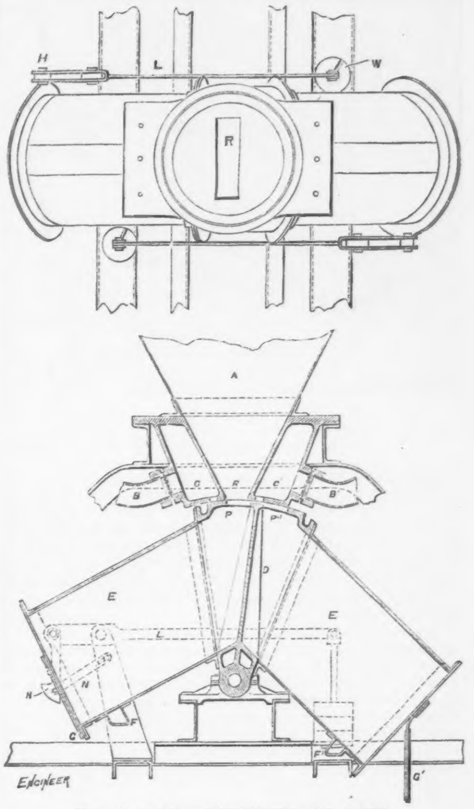
Of the total quantity imported about one-fourth comes to London, and of this nearly one-half is received at the Millwall Docks. It is therefore but natural that the Millwall Dock authorities should be looked to for some improvements in grain-working apparatus.

We believe it was at Millwall Docks that the use of hydraulic cranes, in combination with what is now known as Priestman's grab, was first employed in lieu of the old-fashioned manual process of discharging cargoes by whipping or by grain tub and winch. The self-emptying tub followed, with advantages it possesses under certain conditions over the Priestman. In other ports, notably at Liverpool, the band and bucket elevator found favour, but neither of these was perfect, *e.g.*, in each the grain had to be "trimmed," or moved to within reach of the elevator. Grain stowed in confined spaces could not be touched by the machinery. During wet weather the hatches had to be closed and the discharge stopped. There was always waste from grain dropping on the deck or overboard. There was to the men employed risk and frequent damage, not only from failure of gear, but by working in a cloud of dust, and to the employer there was the element of cost per ton and the difficulties and uncertainties of the labour market.

To lift and convey grain and such like material by the employment of air is no new idea, and it possesses many obvious advantages, but the difficulties have been to get the grain into the conveying tubes, to keep up a constant stream without choking, to separate the grain and other solid particles from the conveying air, to extract the grain automatically from the receiver without reducing the amount of vacuum by which the lifting and conveying is being simultaneously carried on.

The process invented by Mr. F. E. Duckham, and introduced by him at Millwall Docks, seems to have successfully overcome not only the disadvantages of other grain-working machinery, but also the difficulties which have hitherto prevented the employment of air as a medium for grain transmission. This apparatus has got well beyond the experimental stage, for the first machine of this kind, the Mark-lane, has been in almost constant work at the Millwall Docks during the past twelve months, and as a result of its success, a second machine, the Baltic, is just being completed by the East Ferry Road Engineering Works Company for use in the Royal Albert Dock. The general design of this machine is shown by the illustrations on page 64.

To conform with local requirements, the Baltic machinery is in a barge 115ft. long by 22ft. wide by 11ft. deep. It is to be placed alongside the importing ship and discharge grain into, say, four barges simultaneously. Steam is supplied by two boilers of ordinary marine type. The engines are horizontal surface-condensing compound, with cylinders 22in. and 40in. diameter by 48in. stroke. The two piston-rods are prolonged, each to carry the pistons of two air-pumps capable of producing and maintaining a partial vacuum equal to 20in. mercury. On deck are two erections containing the grain receivers, dust catchers, and weighing machinery. When in use each receiver will be connected with the importing ship by a semi-flexible tube, 8in. diameter; and if at the same time the receiver be connected with the air-pumps, there will be an inrush of air through the tubes to the receiver, and from the receiver to the pumps. There were two problems: (1) how to maintain a constant flow of grain through the tubes to the receiver; (2) how to get the grain out of the receiver without reducing the vacuum or otherwise interfering with the suction. The first difficulty has been met by the nozzle, Fig. 3, page 64. This is fitted to the inlet end of the tube, and has an adjustable jacket, so that no matter how much the nozzle may be immersed in the grain, the regular supply of about thirty volumes of air per one volume of grain is kept up by means of the annular passage between the nozzle and the jacket. The second difficulty obviously required an automatic air lock—such as is illustrated by Figs. 4 and 5. This is a twin box, mounted to oscillate on trunnions under the coned bottom of the receiver, one compartment filling while the other empties itself into an open hopper, whence the grain is drawn off through suitable sliding doors to weighing machines, and delivered in sacks or in bulk.



Figs. 4 and 5 — AUTOMATIC AIR LOCK

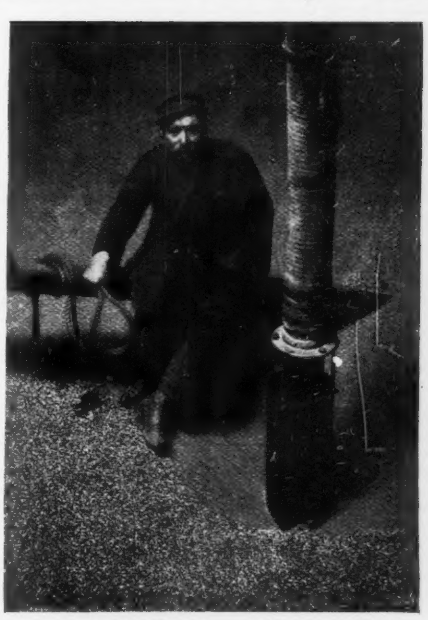


Fig. 6 — GRAIN NOZZLE IN CARGO OF MAIZE

The only disadvantage possessed by this machine, or, at

## BETHLEHEM ARMOUR PLATES

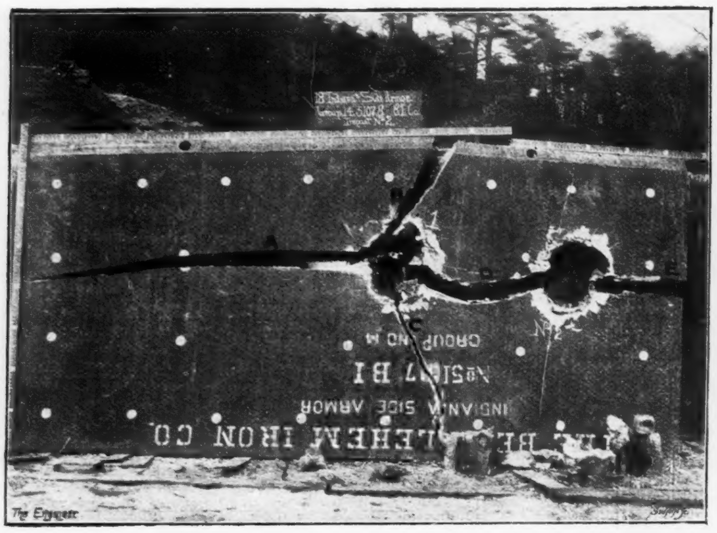

PLATE FOR THE INDIANA

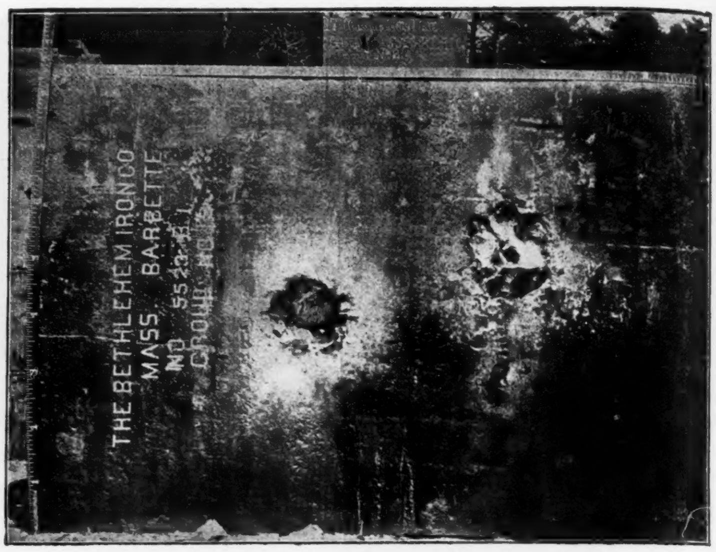

PLATE FOR THE MASSACHUSSETTS

least, the only objection raised by the grain trade, was that the exhaust air carried off some of the dust which is always found in grain, and while its removal improved the quality it reduced the weight of the bulk to a very small extent. The dust catcher is therefore interposed between the receiver and the pumps, and the dust which this contrivance traps is, when desired, returned by a bye-pass into the receiver and re-mixed with the grain, so that the absolute weight of the parcel is then maintained.

The advantages of the process are many. It can be worked in all weathers; its tubes, like limbs of an enormous octopus, reach the grain in any part of the ship; it conveys the grain in enclosed conduits between the ship's hold and the receiving barge or granary, so there is no loss of cargo *en route;* there is to the men no risk; but if one may judge from the reproduced photograph there is comparative comfort, for the only man required per tube may sit and just slack away the fall of the tackle by which the tube is sustained, and so keep the inlet immersed in the rapidly-discharging cargo. The 6in. nozzle shown in the photograph was at that time discharging maize at a speed of 30 tons per hour.

This process may be used not only for the discharge of grain from ships to barges, but also for the loading of ships from barges or granaries. For this latter purpose the apparatus is modified that the grain may first be drawn into the receiver on the machinery barge and discharged thence by air pressure through tubes to any desired part of the export steamer. A machine of this kind is now being made by the East Ferry Road Company for loading grain ex-barge into steamers at one of the foreign grain ports—we hope to refer to this more fully at a later day—and others are being negotiated not only for floating but for land purposes.

As to the capabilities of the process, we understand Mr. Duckham has thereby experimentally raised wheat and maize 80ft. and conveyed the same horizontally 700ft., but has not reached the limits of this method of elevating and conveying.

## BETHLEHEM HARVEY PLATES.

We give herewith a photograph of the Harveyed nickel steel plate tested at Indian head on May 19th last, to which special attention has been called, seeing that it has been thought disappointing as a sample of thick armour subjected to the Harvey process.

The details of the trial are as follows:—The plate measured 15ft. 6in. by 7ft. 6in. It was 18in. thick for a width of 4ft., tapering off for the lower 3ft. 6in. to the thickness of 8in. at the bottom edge. The point of impact of the first shot was 80in. from the right-hand end, and 36in. from the top edge, thus falling in the straight part of the section. The penetration of this shot was about 20in., measured from the face.

The second shot struck 33in. from the right-hand end, and 36in. from the top edge. The penetration was about 24in. from the face of the plate. The projectile penetrated 6in., not 8in. as first reported, into the backing, and broke into small fragments. Cracks A, B, and C—shown in the photograph—were made by the first blow; D and E were opened by the second, but may probably have been started by the first round. The projectile and charge were given in The Engineer of May the 25th, namely, a 12in. Carpenter forged steel projectile, weighing 850 lb., fired with a charge of 269 lb. of prismatic powder in the first round, giving a striking velocity of 1465 foot-seconds, and in the second round fired with a charge of 419 lb. of powder, with a striking velocity of 1926 foot-seconds. The calculated perforations are for the first round about 18·7in. of wrought iron, and for the second, on the English system, 25¼in. of iron, or 20¼in. of steel, and on Krupp's system 27½in. of iron, or 22in. of steel.

The second round was a very severe test. The first round had greatly strained if it had not actually commenced a crack through the point of impact of the second round. At the best it was, in a sense, splitting a plate by driving in successive wedges, and we think that the armour's reputation in no way suffered by the second round. For fracture, the only measure we have is the energy per ton. The energy of the second round was 21,860 foot-tons. The entire plate weighed 33 tons, we believe. This would argue an energy per ton of plate of 662 foot-tons, which is considerable, but seeing that the portion attacked was broken entirely away from the rest of the plate by the first round, the shock must be taken as falling on this mass, which, it may be seen from the figure, formed about $\frac{2}{5}$th of the whole, so that the shock was obviously about 1681 foot-tons energy per ton of plate. This agrees with the estimate made in America, namely, 1683 foot-tons. We noticed in our article the severity of this second round, and the details since received now indicate that we understated the case in absence of full information. This does not, however, apply to the first round, which was undoubtedly disappointing. It is to this that special interest attaches.

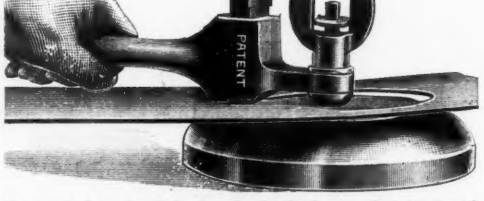
It appears that while this plate was undergoing the hardening process a crack had been heard, and on this account the Government inspectors selected it for test. The makers, we understand, might had they wished it have withdrawn the plate as spoilt work, but they preferred to take their chance. After the destruction of the plate it was seen that the horizontal crack—A D E—was the development of a very large internal crack which had been caused by the water hardening. The extent of this crack was indicated by the discoloration of the fracture. It became apparent, it is said, on the surface of fracture about 12in. to the left of the first hole, and extended nearly to the end of the plate, spreading from ¼in. to ½in. of the hardened surface, to from 1in. to 2in. at the back of the plate. It may be seen that this line is parallel to the angle at the back of the plate, due to the tapering off of the lower part, but it is difficult to connect it with it. The question then arises, How does this bear on the position of Harveyed armour? That the plate was not a sample goes without saying, so that it hardly bears upon whether the Harvey process when completely successful tells less on thick armour than thin. On the other hand, it certainly does apply to the liability of thick armour to suffer in the process, because a plate that the makers were ready to take their chance with under the ballistic test was one that naturally would have been supplied for service. There was no flaw apparent on the surface. Nothing had happened but a loud noise, and it takes a very well-established noise to frighten most makers out of the large sum of money represented by such a heavy plate. After testing and examining, if no defects could be detected in the finished plate, we know practically that the plate would be supplied for the service; nor could makers be blamed, seeing that they had the courage of their choice when brought to face the ballistic test. We may remind our readers that a Tresidder plate failed similarly from a crack in a trial at St. Petersburg more than a year ago; in fact, it is in the water-hardening, which is common to both Tresidder and Harvey treatment, that this trouble has arisen, so that it cannot be fairly traced to the carbonisation process. Can it be connected with the presence of nickel? It would be satisfactory to us in England if we could establish this, seeing that we have discarded nickel partly on grounds connected with such a question. Unfortunately the St. Petersburg plate was a compound one, and contained no nickel. The water-hardening was almost the only element possessed in common by these two notorious plates. Other untreated steel plates have developed flaws at times, and it is clear then that we must wait for further results before pronouncing, in the meantime be specially careful. We think it would be desirable to fire at every plate that makes a noise in hardening, for at present the only alternative would be to reject it. If the finished plate shows no evidence of cracks, purchasers will probably feel that hardening ought to be done in the presence of their inspecting officers. The general tendency of this is to keep up the preference in favour of untreated plates which exists on the Continent. Nevertheless, in spite of any liability to disappointment, the treatment gives such high resisting powers that we cannot but feel that the adoption of treated plates is only a question of time.

Another thick armour-plate of Harveyed nickel steel made by the Bethlehem Company was tested at Indian Head on June 12th last with complete success. The plate was a curved one for the barbette of the Massachusetts. It measures 12ft. 1in. by 8ft. 4¼in. by 17in., and its weight is 30 tons 5¾ cwt. It was attacked like the plate preceding it by 12in. Carpenter forged steel projectiles weighing 850 lb. each. The first round had a striking velocity of 1410ft., implying an energy of about 11,715 foot-tons and a perforation through iron of 17·96in., and through steel of 14·37. A second round had a striking velocity of 1853 foot-seconds, and an energy of about 20,240 foot-tons, implying a perforation of 24·23in. of iron and 19·38in. of steel. The first projectile broke up with a penetration of about 8in., and the second broke up with about 11in. penetration. There was a fine horizontal crack in the plate running from the right side of the second point of impact. The plate was approved, and twenty-six 17in. plates were accepted on its performance. The performance is greatly to be commended. The second blow, it may be seen, represents more than 2in. perforation than the plate attacked, and the shock is 663 foot-tons per ton of plate, the latter being fully as severe as the 18in. plate had been subjected to. The Bethlehem Company is therefore greatly to be congratulated on its success.

We give herewith a copy of the official photograph of the plate after the second round had been fired.

## THE "SUNDALE" HOLE CUTTER.

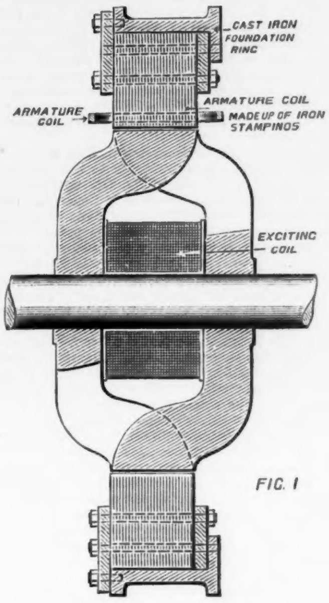
We here give an illustration of a new hole-cutting tool which will doubtless be of interest to shipbuilders, tank and boiler makers, &c. It will cut a true and clean hole in iron and steel plates up to $\frac{5}{16}$in. thick. The illustration clearly shows the method of handling the tool, which is made in nine different sizes for holes from 3in. to 12in. diameter, by Selig, Sonnenthal and Co., of 85, Queen Victoria-street, E.C. The only preparation necessary for its use is the drilling of the central hole. We have seen the tool, and also some of the work done by it, and unhesitatingly say that it should supply a long-felt want to manufacturers who think anything of economy.



The Port of Algiers.—In view of the importance of Algiers as a coaling station for British vessels, the British Consul-General at that town, in a recent report upon the trade and navigation of the Colony, furnishes a description of the port, with suggestions for its improvement. Algiers holds the eighth place among French ports, and shipping entered last year amounting to 776,111 tons, of which British shipping formed 223,939 tons, or 29·9 per cent. Formerly vessels going to and returning from the East used to stop at Gibraltar and Malta to coal. Algiers has been found a much more convenient stopping place, as it divides the distance better between Port Said and the United Kingdom, and is free from the unusually strict quarantine regulations which are enforced at our own Mediterranean ports. The number of British vessels which called at Algiers, for coal only, exclusive of those which brought or took away cargoes, has increased from 85 in 1886, to 1118 in 1893, and the number increases daily, five or six vessels often being in harbour at once. The port, consisting of a great sheet of water and a small basin, called the Darse, is a military harbour, a fishing port, a harbour of refuge, and a mercantile port. In the opinion of the Chamber of Commerce, the port ought to have a double future as a place of repairs if not of construction, there being two docks which are not sufficiently used, and as a port of supply for English vessels going to the East, in which respect it has greatly increased of late. The water area is 222½ acres, a space sufficient for its requirements, but the length of the quays is by no means equal to the demands of commerce, the amount available being only 1400 yards, or 534 tons of merchandise to each yard of quay. The following works, some of which are in progress, and others under consideration, are necessary to make the harbour commodious and safe: Narrowing the entrance and making a new one in the south part of the Mole; lengthening and widening the northern jetty, and replacing its crowning part by better work; renewing the retaining walls of the Admiralty "*clot*"; creating an inner harbour in the bay to the east. The report, Annual Series, No. 1347, contains examples of the charges for loading, discharging, port dues, &c.

## THE NEW "KAPP" ALTERNATOR.

WE illustrate to-day a new dynamo which has been brought out by Mr. Gisbert Kapp, or, perhaps, it would be more correct to say that the machine which he recently showed to a large and distinguished party of engineers, at the works of Messrs. Johnson and Phillips, Charlton, is an improvement on his well-known type of alternator. As every machine which has for its *raison d'etre* the simplification of the generation of high tension electricity must possess for engineers and electricians at this time a very special interest, we commend the new alternator to the careful consideration of all who are interested in electrical generation.



CAST IRON FOUNDATION RING
ARMATURE COIL
ARMATURE COIL MADE UP OF IRON STAMPINGS
EXCITING COIL

FIG. 1

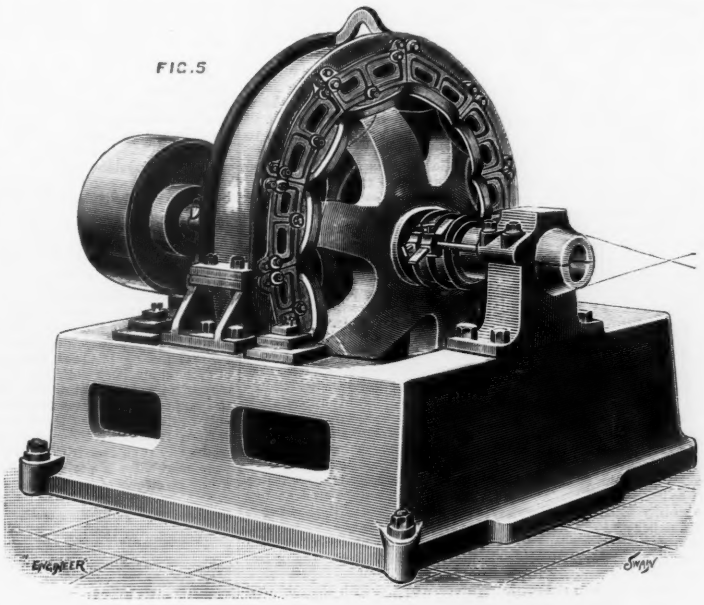


FIG. 5

The machine, which is experimental, is of 20-kilowatts capacity, and when driven at 780 revolutions per minute gives a current of 10 ampères at 2000 volts, and having a periodicity of 93 per second. Unlike his older machines, Mr. Kapp causes the field-magnets to revolve within a stationary armature, a detail of alternator design which, because of its obvious and self-evident advantages, is rapidly becoming universal. The field magnets in the new machine under notice are arranged in a manner somewhat similar to that adopted by Mr. Mordey, in so far as that the winding consists of only one coil and that they are claw-shaped; but unlike the Mordey field, in which the faces of the pole pieces are at right angles to the shaft, in that the faces of the pole pieces are parallel to the axis of the shaft. This is shown in the rough sketch marked Fig. 1. The magnets are of cast steel, made in two pieces, one of which is keyed to the shaft, while the other is held in place by means of a collar. Upon the shaft, and between the magnets, the exciting coil is placed, which makes each pole face alternately north and south, there being fourteen faces, or seven of each polarity in the machine. The clearance between the field magnets and the armature is $\frac{1}{8}$th of an inch, and though this might even be reduced, such a clearance has been found in practice to be sufficient for good regulation. The armature coils are wound over cores formed of charcoal iron stampings, and as each coil is wound separately, and is in the process of its winding thoroughly covered with rubber tape, we can quite understand Mr. Kapp's confidence when he assured his visitors that a hose being played over his machine would produce no evil consequences. The iron core stampings are as shown in Figs. 2 and 3, and they are held in place in the machine by means of bolts which pass through a gun-metal clamp at each end of the bunch, and the method of fixing the whole thing, core and clamps, to the embracing cast iron ring is sketched in Fig. 4. The faces A and B are turned true, and are parallel to each other. The faces of the gun-metal clamps are also machined, so that each section of the armature, as put in place, is kept rigid and quite true, both with respect to the field magnets and to the other sections of the armature itself. As all the coils of the armature are, when fixed in place, connected in series, the machine possesses many advantages over others in which two or more sections are in parallel, and no effect due to difference in electromotive force between halves or quarters need be feared. The points of the greatest difference of potential can be efficiently insulated in a stationary armature in such a way that they can withstand the wear and tear of central station work without any special attention; but indeed the greatest care has been devoted to the design and manufacture of the new alternator, so that it shall require the least amount of skill to keep it in efficient repair and satisfactory working order. The armature is so insulated that there can be no leakage, and if by chance an armature coil should burn out, it is possible to stop the machine—as was shown—take out the damaged coil, replace it by a spare one, connect it up, and be running again in between five and six minutes. As every section of the armature is machined and wound to a template, there is no difficulty in arranging for such an interchange of parts. The coils of the armature are easily wound, require no expensive winding gear, and can be insulated and put together by the switchboard attendant at the station, while the cost of repair of such an alternator must be very small.

FIG. 2

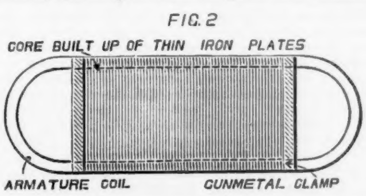

FIG. 3

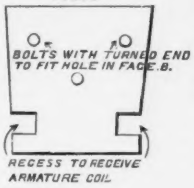
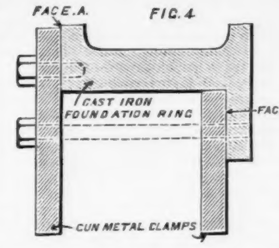


BOLTS WITH TURNED END TO FIT HOLE IN FACE.B.
RECESS TO RECEIVE ARMATURE COIL

The advantage of the capability of the machine for the replacement of damaged coils so promptly, is one which will recommend itself to the favourable attention of central station engineers, who know what valuable time is frequently lost in repairing alternators owing to absence of interchangeability of the different parts.

One peculiarity of the machine which Mr. Kapp wished especially to demonstrate was the fact that it might be short-circuited without fear of damage—indeed, with impunity, and this he showed in the following way:—The machine, working with an output of 20 kilowatts, was suddenly short-circuited and was left working on the "short." At first the engine ran away, acting as if connected to a shunt-wound dynamo, the armature completely demagnetising the field magnets. Then it slowed down to its normal speed as the governor asserted control, and the dynamo gradually worked on the short until it produced a current of 35 ampères, with no E.M.F. apparent on the voltmeter.

FIG. 4



In the ordinary working of a central station this would mean that, should a pair of mains short-circuit, the dynamo would work on the short circuit without straining the engine, the fuse or cut-out would then fail, and the E.M.F. come up slowly to normal pressure, and not suddenly, as in the case of a machine with very little self-induction. This property of being short-circuited with impunity is, perhaps, of more value in the case of two alternators running in parallel than in any other case, as it is possible to suppose that with two alternators working in parallel and the field of one of them suddenly broken, the second machine would be immediately short circuited, and the consequences in the case of machines without self-induction in the armature would be very grave. But in this machine the effect would simply be that the moment the field-magnet circuit was broken on the alternator there would be a fairly high resistance, viz., the armature of the broken-down alternator in parallel with the external work on the second alternator, and would simply mean an excess of current being supplied by the second alternator, the lights need not necessarily be extinguished, and not any damage done to the machines. It is a question whether this property of being short-circuited will recommend itself to most electric station engineers, their principal anxiety is that the light should be kept going; and with machines such as the Ferranti or Mordey type, a short circuit is so very quickly disposed of that nothing is thought of it; but if it takes ten or fifteen seconds to dispose of one by means of a machine similar to Mr. Kapp's, the patience of the consumers would be very severely tried. On the other hand, the sudden short-circuiting and its sudden removal with very high E.M.F. tends to put a severe strain on the insulation of every part of the system, and the consequence is generally the breakdown of some part of the plant by it, dynamos, mains, and transformers; the first two are not very serious to the consumer, but the latter affects him so long as it is out of order.

The exciting current in Mr. Kapp's machine is 1·3 per cent. of the total load, but this can be made as low as ·6 per cent. in machines of larger size, and the drop in volts from no load to full load is under 12 per cent.

---

## THE RELATION OF THE DRAWING OFFICE TO THE SHOP IN MANUFACTURING.*

By A. W. ROBINSON, South Milwaukee, Wis.

THE purpose of this paper is to describe the system employed by the writer in the drawing-office of his company in the hope that some of the points may be of use to members of the Society. The drawing-office is the origin of thought and action for the entire works as far as the design and construction of its product are concerned. It is responsible for the accuracy of its drawings and orders, and its authority should be unquestioned and above reproach in the shop. The shopman should habitually trust and adhere to their drawings, and their faith should not prove to be misplaced. To maintain this there must be unceasing care and vigilance on the part of the office, and full adaptation to the shop needs and capabilities. It goes without saying that every drawing-office, whether employing one draughtsman or a hundred, should have its system and methods adapted to the needs of the establishment with which it is connected. As these needs vary with each case, it is not to be supposed that the system about to be described will be of universal application. It will be well, then, to state in a general way the conditions which this system is intended to meet. We will assume, therefore, that the office employs from ten to fifteen skilled draughtsmen, and is in connection with a manufacturing establishment, doing a general engineering business in which there is comparatively little duplication of orders, and in which single orders frequently involve a large amount of detail, of which it is essential to keep exact records. It is also assumed that the drawing-office is invested with the sole right and authority to issue orders to the shop for all new work, or all work in which there are changes and variations from previous similar work. The practice of issuing verbal orders or directions for the conduct of work is productive of misunderstanding and confusion. When no evidence of authority exists no responsibility can be fixed. It is therefore advisable to have a system of written orders to all departments whereby the duty of those concerned is clearly defined, and the responsibility can be fixed for dereliction of duty.

*Shop orders.*—An order being once entered on the books of the company, the procedure is as follows:—The business office issues a written order to both the drawing-office and the shop upon a blank which merely states the general name of the machine, the time of delivery promised, and the number of specifications to be worked to, if any, and the number by which the order is to be known. It is the duty of the drawing-office to prepare such specifications beforehand when necessary. On the receipt of these orders in the shop, if it be a repair or duplicate of something already made, so that the shop superintendent has the information by which to execute it, he does so. If, however, it is new, or in any sense special work, he cannot proceed until the orders come down from the drawing-office. The drawing office issues orders upon the pattern shop and foundry by means of blanks headed "Foundry" or "Pattern shop," as the case may be, arranged thus:—

B. S. S. & D. CO. ENGINEERING DEPARTMENT.
FOUNDRY ORDER.

| | | |
|---|---|---|
| ORDER NO. | DATE.<br>189 | DRAUGHTSMAN. |
| | | |
| Countersigned by | Examined by | |

These are manifolded in triplicate, and can be made out by any draughtsman to whom the job is delegated, but must be signed by the chief engineer, or in his absence, the chief draughtsman. The two copies are then sent down to the shop superintendent's office, who keeps one on file for his own reference and information, and immediately sends the other to the foreman of the department for which it is intended. In this way the shop superintendent retains control of his men in the different departments, and has knowledge of the orders that are issued. He alone is responsible for their proper execution, and undue interference of the draughtsman with the foremen or workmen is obviated. It is also the duty of the drawing-office to order all raw material for new and special work, that is not regularly kept in stock. This is done by blank as follows:—

B. S. S. & D. CO. ENGINEERING DEPARTMENT.

| | |
|---|---|
| DATE.<br>189 | Please order the following<br>for order No. |
| Ship | |
| Draughtsman | Countersigned<br>Chief Engineer. |

These are simply requisitions on the business office, and the copy goes to the storekeeper as a statement that the articles noted have been this day ordered. He will therefore be expecting them, and on their receipt will at once know for what order they are intended. His copy of the manifold reads, "The following material has this day been ordered for order No. —." Written orders are not issued from the drawing-office to any other departments, except the pattern shop and foundry. Drawings and sketch sheets are issued to the other departments, as machine, smith, and erecting shop, &c. These pass through the hands of the shop superintendent, and in themselves constitute an order to make what they represent or call for, provided they are covered by the original general order from the business office and bear the same order number.

By means of these written orders to each department, each foreman knows definitely what work he has on hand, and all responsibility for errors or delinquencies is at once traceable to the culprit. The shop superintendent is also empowered to issue written orders to his foremen in all departments, for all work which does not require information from or the authority of the drawing-office. For these he uses his own blanks—those of the drawing-office being labelled "Engineering Department." It frequently happens that on large orders involving much detail, it is desirable to push the construction of parts as fast as they are determined upon before the completion of the general design. In these days of urgency and high pressure this is almost a necessary evil, but should be pursued with caution in the drawing-office, lest difficulty be found in fitting the later part of the design to the earlier. Under this system of written orders the parts can be ordered in as fast as they are ready, even though the shop superintendent is as yet uninformed as to the balance of it, and does not know of what the complete order is to consist. When the drawing-office work on the order is completed an order list is made out and typewritten in duplicate. The order list enumerates in detail all the items making up the complete order, and is divided up into headings, such as—(1) castings; (2) forgings; (3) miscellaneous; (4) special material ordered outside, and so on. For each item is given a reference number of the drawing or sketch sheet on which it is shown, and it is or should be shown thereon so fully and definitely that no further questions need be asked. This order list is essential—first, to inform the shop definitely of what the work consists; secondly, to refer the shop to a source of information concerning each and every item; thirdly, to form a shipping list so that in shipment nothing will be overlooked that should be sent; fourthly, to form a permanent record by which repairs may be readily identified, and from which future machines may be compiled or adapted. These order lists are press copied in a book for the purpose.

---

* Presented at the Montreal meeting—June, 1894—of the American Society of Mechanical Engineers.

*Drawings.*—The primary function of a shop drawing is to answer the shopman's questions, and, indeed, it may be said this is its only function. There are certain things connected with the material, form, dimensions, finishing, fitting, and erecting of a machine and each part of it, that each department needs to know. Sometimes in simple cases the various processes of pattern-making, finishing, and erecting, can be defined on one drawing, and in other cases separate drawings containing separate information for the different processes are demanded. It is important to have all the necessary information conveyed on a drawing in a direct and legible manner, and that the views be so chosen as to represent the object in the simplest way. Let the draughtsman, on beginning to make a shop drawing, say to himself, "Now what does the fellow who is to make this want to know," and then let him put down just that information and no more, but be sure and get it all on. Refrain from all superfluous lines and marks, and make the drawings so plain that "he who runs may read them." The mere ability to make lines and circles and projections is really the least important and least valuable part of a draughtsman's skill. Neatness and accuracy of drawing is desirable, but if it is obtained with the expenditure of an undue amount of time, and does not carry with it a practical knowledge of shop needs and shop processes, it ceases to be a virtue. The following set of rules for the drawing-office have been found to be useful and to work well. They contain some points that a good draughtsman ought to know, but they are incorporated as reminders, and as being necessary to preserve uniformity of practice among changing draughtsmen.

### DRAWING OFFICE RULES.

*Shop drawings.*—(1) All drawings shall be of the uniform size of 23in. by 36in. (2) All detail drawings for use in the shop shall consist of whole standard sheets, half standard sheets, and sketch sheets. Half sheets shall be 18in. by 23in., formed by ruling a line across the centre of standard size sheets as filed, the blue prints only to be cut, and mounted, and varnished when necessary. (3) The sketch sheets shall be 8in. by 11in., and shall be used for all simple details, forgings, for bolt lists, and for all temporary work capable of being shown in this way. All standard machines shall be fully drawn out and blue printed. The sketch sheets shall be made with indelible pencil or copying ink and press copied in the book for the purpose. The information on the sketch sheets shall be as complete as that specified for drawings.

*Character of shop drawings.*—(4) A shop drawing is to be considered as an order or instructions to the shop, and not merely as a statement or illustration. For this purpose it must convey clearly all the information needed to make and finish the article. (5) Every dimension necessary to the execution of the work is to be clearly stated by figures on the drawing, so that no measurement need be taken in the shop by scale. All measurements to be given with reference to the base or starting point from which the work should be laid out. In comparatively simple constructions the several parts are to be shown together complete, although each part must be figured independently, and details supplied, if necessary, by sketch sheet. In more complicated forms each part should be detailed by itself and a general drawing made showing the thing complete. No details should be sent out without putting them together on a drawing, or taking them from a general drawing, so as to ensure their fitness. Unnecessary duplication of views to be avoided, except in display or advertising drawings. (6) All figured dimensions on drawings to be plain, round vertical figures, not less than ¼in. high, and formed by a line of uniform width, and sufficiently heavy to ensure printing well, No thin, sloping, or doubtful figures or diagonal-barred fractions will be tolerated. All figured dimensions below 3ft. to be expressed in inches. (7) All centre lines to be alternate dot and dash in fine black line. All dimension lines to be in continuous red lines with a central space for the figure, and of such strength as to show on blue print more faintly than lines of drawing. Lines of drawing to be bold and clearly defined in proportion to the scale, and to be shade-lined by making the right-hand and bottom lines heavier. No ornamental shading or other "frills" allowed on shop drawings.

*Title.*—(8) Every drawing, whether whole or half-sheet, shall have the title, date, scale, and number of the sheet placed in lower right-hand corner. One man will be detailed for this duty, to secure uniformity. (9) The name of the drawing, as given in the title, is invariably to consist of two divisions in one line, separated by a hyphen. The first division is to state the general name of the thing or machine, and the second division is to clearly designate the part or parts represented—or if a general view, should so state. The wording of the titles should be submitted to the chief engineer or head draughtsman for approval.

*Drawing symbols.*—(10) Detail shop drawings should state:—(*a*) The pattern number of every casting in plain figures of larger size than the dimension figures. (*b*) The number of each piece required for one set. This should be written in one word—not figures—and followed by symbol of material. (*c*) The material of which the parts so ordered are made, using symbols as follows:—C.I., Cast iron; W.I., Wrought iron; C.S., Cast steel; M.S., Machinery steel; H.S., Hammered steel; Bs., Brass; Bz., Bronze, Bbt., Babbitt; V.F., Vulcanised fibre; C.R.S., Cold rolled steel. Other materials write full name. (*d*) The kind of finish on each of the different parts will be indicated by a letter preceding the figured dimensions, as follows:—F. means "Finish," and indicates that the surfaces to which it applies are to be machined or dressed in suitable manner to size stated. F.B. means "Finished bright," or polished. G.F. means "Grinding finish," and indicates that the only finish to be allowed is that necessary for grinding. When no letter precedes the figured dimension it is understood that the part is to be left black or rough. In cases where finish might be presumed but not required, follow the figured dimension by the word "Cast" if a casting, and "Rough" if a forging. (*e*) A reference list of sketch sheets that may be used for detail illustrations.

*Sketch books.*—(11) Each draughtsman will be supplied with a sketch-book by the company, and in which he shall make all his notes, calculations, and data referring to his work, and under no circumstances shall original work be done on loose sheets and transcribed into these books. No effort should be made at neatness or nicety in these books, but each entry should invariably be commenced with the name of the thing and the date, and full notes made of data on which the calculations were based, and the results obtained clearly stated. These books are to be the property of the company.

*Index for drawings.*—(12) An index book for drawings will be kept in the drawing-office by the clerk. This book will be divided into as many divisions as there are drawers, with provision for indexing 100 drawings in each drawer. The names of the drawings will be added to the various divisions according to their classification. The system of numbering shall be as follows:—(13) Each drawer shall be numbered consecutively, and shall contain drawings devoted to a certain class of work, which shall be indicated on the drawer label. The drawing number shall consist of two or more digits with a decimal point between them. The whole number shall indicate the number of the drawer, and the figures after the decimal point shall indicate the serial number of the drawing in that drawer. For example: Drawing No. 5·16 is the 16th sheet in Drawer No. 5, and Drawing No. 75·96 is the 96th sheet in Drawer No. 75. Not more than ninety-nine drawings shall be put in one drawer, except in exceptional cases. (14) Sketch sheets will bear the number of the letter and page of the letter book, preceded by the letter S, to distinguish them from drawings, and will be indexed in their own impression book, but not in the drawing index book. They will be referred to on general drawing of which they are details, and will also bear the number of such drawing. (15) When making a new drawing the draughtsman will apply to the clerk for a number, and will be allotted the first unappropriated number in the division to which the drawing will belong. (16) On completion of every drawing or sketch sheet it must be examined and initialled by the engineer before being issued, and the following entries made in books kept for the purpose:—(A) Record of blue prints and sketch sheets issued to shop, giving date, number, and title. (B) Drawing index—Record in day-book the number, title, and sub-title, draughtsman and date. (C) Pattern index—Record in day-book the number, classification, and correct name of patterns, with remarks and date. Each draughtsman will see that these entries are properly made.

*Patterns.*—(17) All patterns shall be numbered with the number of the drawing from which they are first made, followed by a letter indicating its serial on that drawing. For example, if four patterns are shown in detail on drawing No. 36·50, the patterns shall be numbered 36.50A, 36.50B, 36.50C, 36.50D. When existing patterns are utilised in a new design or machine, their original number is to be noted on the drawing on which they are shown in their new employment. (18) Upon receiving formal notice from the pattern shop that patterns are ready for inspection, the draughtsman connected with the order shall examine same and issue foundry order for the casting. The date of inspection and name of inspector shall be entered upon the pattern maker's report at the time of making such inspection.

The sketch sheets referred to in these rules are 8in. by 11in. in size. They are of stiff cardboard, and the heading is printed in copying ink. The sketch is made with an aniline copying pencil, the "Eagle No. 2" in wood being used. They are press-copied in books for the purpose, and several books are used for different classifications of work. The books are of slightly heavier tissue paper than is commonly used for correspondence, and have 500 leaves each, numbered consecutively throughout the series, so that the number of a sketch sheet is never duplicated. In this system there are six books for copying sketch sheets, representing as many classes of work, and these divisions will readily suggest themselves as required for any particular case. The use of these sketch sheets is especially for work which does not require to be often duplicated, and for giving quick dispatch to emergency work. A freehand sketch can be made, copied, and issued in this way in ten minutes, while the regular process of drawing, tracing, blue printing, and waiting for the latter to dry, or the sun to shine, may consume hours. They have the additional advantage of being more convenient to handle and file away in the shop than blue prints, and they save multiplications of tracings and consequent drawer space. The copies being in book form cannot be lost and are easily indexed and consulted. Sketch sheets are convenient for rapid detailing of forging and small parts, and such parts need, therefore, to be merely indicated on the general or erecting plan, and reference numbers given of the sketch sheets. The sketch sheets will also all appear as items in the order list. In addition to the stiff card sketch sheet, it is convenient to have a "Drawing-office Memorandum" blank. This is a copying-ink heading printed on a sheet of letter paper, and is used for order lists and all sketch matter sent abroad from the drawing-office. After copying, the sketch sheet, if for permanent use, is sized with a mucilage, composed of gum tragacanth and water, and then varnished with white shellac and alcohol. The sizing is to keep the lines of the sketch from running while varnishing.

Two necessary articles of office furniture are the drawing table and the blue-print frame. So many excellent forms of these have been devised that it seems hardly necessary to refer to them in this connection, but sometime hereafter occasion will be taken to describe types which have the merit of cheapness and effectiveness. It is our practice not to finish original drawings, but to trace from them on tracing cloth. These tracings are used only to print from and are filed away in a fire-proof vault. Two prints are made of each tracing as soon as finished, one for the shop—or more if necessary—and one to file away in the drawers of the office. These drawers are 24in. × 38in. × 2in., and are each calculated to hold a maximum of 100 prints. In this way the tracings are preserved from risk of fire and loss and from the wear of frequent handling. As a rule each draughtsman makes his own tracings, and only skilled draughtsmen are employed. The writer does not advocate the employment of cheap draughtsmen to trace shop drawings from the originals of the designer. If this is done the designer must finish his original to entire completeness before turning it over to the tracer, thus consuming additional time and running more risk of errors and omissions than if he traced it himself. A skilled draughtsman will merely block out his entire work on the original and give his whole thought to the perfection of his design. In the tracing he can re-arrange his drawing if necessary, and the time occupied in tracing is usually much less than that employed in working out and perfecting the design, and a draughtsman worth 120 dols. per month will usually trace twice as fast as one worth 60 dols., and do it better. The titles on drawings are mainly done by rubber stamps giving the name of the company, the number of the drawing, and having spaces for the insertion of name, date, and scale. Some experimenting was done to find a suitable stamp ink for tracing cloth. Printers' ink was tried; but it rubs off, and does not dry satisfactorily. A special lithographic ink is used, which is similar to printers' ink, but with the addition of a dryer. It is applied to the stamp by a composition roller, in a similar manner to printers' ink, and gives a black impression which blue prints well. The number stamp has movable type. As a rule, it pays to employ only high-class labour in the drawing-office. A draughtsman puts his own impress on his work, his individuality goes into it, even if closely supervised, and it is upon the perfection of detail that the success or failure of a new design mainly depends; it is important that the draughtsman entrusted with it shall have the necessary skill and ability. We have appliances for testing the efficiency of almost every known mechanism; but who can measure the efficiency of the draughtsman. We appreciate the economic value of good steam distribution and the like; but too often is the efficiency of the draughtsman neglected, and thousands of dollars spent in the construction of work which would have yielded much better results if a little more brains had been used in its design.

In conclusion, the writer would say: Do not have so much system that it is difficult to work to or burdensome to carry out. A few simple rules, faithfully adhered to, are better than the most elaborate system which is loosely or imperfectly carried out. The object of a system is to define the duties of each man and to fix the responsibility of dereliction of duty.

---

NAVAL ENGINEER APPOINTMENTS.—The following appointments have been made at the Admiralty:—Engineer—A. H. Moysey, to the Australia—lent. Probationary Assistant Engineers—H. J Loveridge, to the St. George; G. H. Dureton, to the Iphigenia; C. J. M. Wallis, to the Rainbow; F. A. Gordon, to the Sybille; and R. C. Cleave, to the Apollo. Assistant Engineers for Temporary Service—F. J. Rockrudge, to the Indefatigable; F. C. Haste, to the Intrepid; G. J. Sisley, to the Victory (supernumerary); F. E. P. Haigh, to the Sappho; W. F. Montgommery, to the Scylla; and T. Pearce, to the Andromache.

---

## THE IRON, COAL, AND GENERAL TRADES OF BIRMINGHAM, WOLVERHAMPTON, AND OTHER DISTRICTS.

(*From our own Correspondent.*)

AT the works this week there has been a quickening of activity, and a fair amount of business is in hand for the remainder of the quarter, so that on the whole manufacturers are in a more cheerful mood than for some time past. Harvest prospects are also improving the home demand for galvanised and other descriptions of iron. Should the wheat harvest realise anticipations, the position of the iron trade in a few months time is bound to be greatly improved. Galvanised corrugated sheets at present are quoted nominally by the Galvanised Iron Trade Association £10 to £10 5s. for 24 gauge sheets, f.o.b. Liverpool, but there is no difficulty in obtaining serviceable material of the same gauge at £9 15s. to £9 17s. 6d. Black sheets for use by the galvanisers continue to be quoted in some cases as low as £6 10s., or even £6 7s. 6d. for doubles. Best thin sheets for deep stamping purposes are in good demand at £10, and ordinary coal vase sheets run from £7 up to £8 10s., according to quality; £8 to £8 10s. is asked for boiler plates, and £6 15s. to £7 for tank plates. The demand is somewhat slow in both cases.

In the pig iron trade the furnaces are making a larger production than lately. Cinder pigs are 37s. 6d. to 38s. 6d.; part-mines about 42s., and all-mine hot blast, 57s. 6d. upwards; with cold blast, 97s. 6d. Midland sorts are in fair demand. Derbyshires are 42s.; Lincolnshires, 44s.; and hematite, 53s. Consumers' needs are in some cases covered till the close of the year.

Constructional engineers have lately received some good orders for bridge and roofing work for India and other Eastern countries. The railway wagon building firms have also got a considerable amount of work on hand for lines in India, Egypt, and elsewhere. The axle-tree firms are fairly engaged, though they are experiencing no particular pressure.

I am in a position to announce that the Great Western Railway Company is intending to erect at Wolverhampton, on premises near the main line, buildings for the manufacture of oil gas for the lighting of railway carriages on the company's system, similar to the works having the same object now existing at London, Exeter, Swindon, New Milford, and Bristol. At present, the nearest point for supplying the train service in the Wolverhampton and Birmingham district with the light is London, and the want has long been felt of having a supply nearer at hand. Full operations at the new works will, it is expected, be in progress by the winter, and the method of charging the carriages is so simple that a matter of two or three minutes is all that is required. The illuminant will be conveyed from the works to the station through piping, and storage facilities at considerable pressure will be provided underneath the carriages sufficient to secure a supply for from eighteen to twenty-four hours.

Makers of railway wheels and axles and other railway materials here are interested in the reply of the Secretary of State for India in the House of Commons a few days back to the question of Sir James Kitson. The interrogator called attention to the statement made by the Chairman of the East India Railway, who had asserted that continued difficulties were met with in obtaining funds from the Government of India to meet reasonable requirements of traders for increased or improved accommodation. Mr. Fowler replied that the East Indian Railway Company was at present, under its constitution, dependent for outlay in the nature of capital expenditure on the limited funds at the disposal of the Indian Government for such purposes. It was, in his opinion, very desirable that means should, if possible, be provided by which the requirements of that system might be more largely met in the future, and the subject was now under his consideration in council. The difficulty did not arise in connection with other Indian railways, which possess the power under their constitution to raise funds, with the sanction of the Government, for the purpose of their several undertakings.

At the forthcoming Trades' Union Congress a resolution will be brought forward by the United Chain Makers' and Chain Strikers' Association demanding that all chains to be used where there is risk to life and property shall be subjected to public tests and to the strictest scrutiny and examination. At a meeting of the last-mentioned body at Dudley recently, it was alleged that "under the present system there was a large quantity of chain, unworthy of the name, made by unqualified workmen, and exported under bogus certificates to the detriment of English trade."

---

## NOTES FROM LANCASHIRE.

(*From our own Correspondent.*)

*Manchester.*—Speculation as to the probable outcome of the suggested terms for a settlement of the general wages question, so far as it concerns the coalowners' and miners' federations, has been one of the most prominent questions during the past week. The general feeling has been that, notwithstanding the strong division of opinion amongst both the coalowners and the miners from their respective points of view with regard to accepting a settlement on the proposed basis, some such arrangement ought to be come to, not only in the interests of the coalowners and the miners, but of the various important industries dependent upon fuel supplies, by which any such disastrous dispute in the coal trade as that of last year might, for a period, at least, be rendered impossible. The injurious effects of the last prolonged stoppage of the pits have not yet by any means been overcome, and the general opinion is that another such disastrous dispute would go very far towards destroying any possibility of improvement in the iron and engineering trades for a considerable time to come.

Only a very limited weight of business was put through in the Manchester iron market on Tuesday, one or two special conditions operating to induce buyers to hold back from placing orders except for absolute immediate requirements. In the first place the strike of miners in Scotland would seem to be very near the point of collapsing, and in the second place the proposed general settlement of the wages question in the Midlands, including a reduction of 10 per cent. on the present rate of wages, and a binding agreement over the next two years, which would prevent any renewal of wages disputes during that period, are looked upon as possibly tending to give an easier tone to prices for pig iron. Merchants and speculative dealers would, at any rate, seem to view the situation in this light, as they are cutting in very low to secure business, and, generally, orders could have been placed on more favourable terms than would have been accepted last week. Lancashire makers of pig iron are so altogether out of the Manchester market, owing to the extremely low prices now ruling for district brands, that their quotations are, as a rule, only nominal. At the works they remain at about 39s. to 40s. for forge, and about 42s. for foundry, less 2½, and where they have exceptionally low rates of carriage they are able to book occasional small orders, but apart from this they are doing practically no business of any moment. With regard to district brands, makers' quotations for Lincolnshire remain about 38s. 6d. for forge, to 39s. 6d. for foundry, net cash, delivered Manchester, but about 3d. under even these low figures is being taken where orders are to be got, and merchants in some cases have been quoting 6d. under the makers' prices.

Derbyshire foundry brands just now meet with very little sale in this district, and 44s. 6d. to 45s. 6d. net cash would represent about the prices which would be taken for delivery here. Outside brands offering in this market, taking them all round, are easier. The leading Middlesbrough makers are still quoting 44s. 4d. net cash for good foundry qualities delivered equal to Manchester, but merchants are sellers at 6d. to 9d. under these figures. There are still very few makers' quotations in the market for Scotch iron, but through second hands Eglinton could be readily bought at 45s. 6d. net prompt cash, delivered at the Lancashire ports.

The manufactured iron trade remains without appreciable improvement; here and there perhaps a little more business is reported to be stirring, but forges generally continue very short of orders, and prices are weak. For Lancashire bars £5 7s. 6d. is now the general quotation, and for Staffordshire £5 10s., but even at these figures there is some little giving way where anything like favourable specifications are concerned. Lancashire sheets average about £6 17s. 6d. to £7 2s. 6d.; and Staffordshire, £7 5s.; Lancashire hoops, £5 17s. 6d. for random; and £6 2s. 6d. for special cut lengths, delivered in the Manchester district.

In the steel trade only a very slow business is still reported, with prices anything but firm; ordinary foundry hematites are still nominally quoted at 52s. 6d., less 2½; ordinary basic billets at £4 net cash, but they are obtainable at less. Makers of steel boiler plates quote £6 10s., with, however, lower sellers in the market, and local makers of steel hoops have reduced their quotations 5s. per ton.

In the metal market business is still only very quiet, but list rates for manufactured goods remain as last quoted.

The position as regards the engineering industries shows no general improvement. Here and there establishments are getting rather busier on special work, and locomotive builders are better supplied with orders than they have been recently, but taking the trade all through, establishments continue only very moderately engaged, and the outlook as regards the future is not at all hopeful.

With regard to the usual monthly reports issued by the trades union organisations connected with the engineering industries, if there is any change at all in the general position it is scarcely in the direction of improvement. The Amalgamated Society of Engineers have this month a considerably increased number of out-of-work members on the books, but this is due mainly to the moulders' strike in the North of England, which has caused some five or six hundred members of the above society to be thrown out of employment, and has brought the number of out-of-work members in receipt of donation benefit to between 9 per cent. and 10 per cent. of the total membership of the society. In the Manchester district the position if anything is slightly better. This is due chiefly to increased activity amongst locomotive builders already referred to, which has resulted in a considerable number of out-of-work members having been taken off the books during the last few weeks. Other trades, however, throughout the district remain much as they were, and reports from other centres do not show any improvement whatever as regards the general position in the engineering industries. As regards the Steam Engine Makers' Society, the monthly reports are not yet fully completed, but it is expected they will show a slight improvement in the general position, except in the marine centres; there are still, however, rather more than 5 per cent. of the total membership on donation benefit.

The second summer excursion in connection with the Manchester Association of Engineers took place on Saturday last, when, with the object of enabling the members and their friends, including ladies, to view the entire route of the Manchester Ship Canal, the Council specially chartered a saloon steamer—the Daniel Adamson—which, with a party numbering about 150, left the Trafford Wharf, Manchester, at noon, and arrived at the landing-stage, Liverpool, at 5 p.m. During the journey the members and friends, who were accompanied by the President, Mr. Thomas Daniels, M.I. Mech. E., had a full opportunity of inspecting all the important works along the canal, and the trip was one of special interest throughout. On arriving at Liverpool the party proceeded to the Bear's Paw restaurant, where they all sat down to tea, and the return journey to Manchester was make by a special express train, leaving the Central Station, Liverpool, at nine o'clock.

In the coal trade business during the past week has to a very large extent been held in abeyance pending the decision of the Conciliation Board with regard to the wages settlement. In the better qualities of round coal the demand for house-fire requirements has fallen off to the smallest possible dimensions, and common round coals have been only in hand-to-mouth request for iron making, steam, and general manufacturing purposes, the depressed condition of the large coal-using industries still largely affecting the demand for steam and forge coals, and for the moment users are not disposed to enter into forward contracts. Quoted prices remain unchanged, but to secure business there is a good deal of very low cutting, and colliery proprietors who hold to late rates are undersold by cheaper supplies offering in the market. Best Wigan Arley averages about 11s. to 11s. 6d.; second qualities of Arley and Pemberton four-foot, 10s. to 10s. 6d.; and common house coals, 8s. to 8s. 6d., with steam and forge coals about 7s. per ton, at the pit mouth. With regard to engine classes of fuel, supplies are still more plentiful in the market, with a tendency to ease down in prices. The lower qualities of slack especially are weaker, and are readily obtainable at the pit mouth at 4s. to 4s. 6d., whilst 5s. to 5s. 6d. is about the average for medium qualities, and 6s. to 6s. 3d. per ton for the best sorts of slack.

For shipment a fair amount of activity is still maintained, but the probability that the Scotch miners' strike may soon be settled tends to check markets which usually get supplied from Scotland placing orders here. Notwithstanding this, however, sellers experience no difficulty in securing the slight advance which they recently put upon prices, and for ordinary Lancashire steam coal, delivered at the ports on the Mersey, about 9s. to 9s. 6d. per ton is being readily obtained.

*Barrow.*—There is a very quiet tone in hematite pig iron, and the sales reported during the week are small and unimportant. Makers are short of orders, and even with only thirty-six furnaces in blast they are acumulating stock. Thirty-nine furnaces are standing idle. Bessemer iron is selling mainly to local users, who are, however, not buying largely forward, most of the business doing is on prompt account. Sales of forge and foundry iron are very small. Prices are easy at 44s. net cash warrant iron sellers, and 43s. 11d. buyers. Makers quote 44s. 6d. to 45s. 6d. for mixed Bessemer numbers, but sales are generally below these figures.

Iron ore finds a very poor market, and the limited extent of local sales is now augmented by the fact that sales to Scotch users have been reduced considerably. Prices, however, do not show any material change; 8s. 6d. is still the quotation for ordinary qualities net at mines. Lower prices are impossible under present conditions.

The steel trade shows no new life in any department. There is a very poor inquiry for steel rails, which are quoted at lower prices—about £3 12s. 6d. for heavy sections. Very few orders are in the market. Foreign and colonial orders are scarce, and it is from this source that most trade is expected. In light rails very little inquiry is experienced. A fair but not brisk inquiry is reported for steel shipbuilding material, and the mills are fairly busy. Billets and hoops are in fair request. Tin bars are quiet. Slabs, wire rods, and blooms are in poor demand.

The shipbuilding trade is brisk, so far as the work in hand is concerned, but very little inquiry is being made in reference to new tonnage. The Naval Construction and Armaments Co. has this week received an order to build a 1000-ton steam sludge boat for the London County Council, for the carriage of sewage out to sea. This is the sixth order which has been placed at Barrow for this class of steamer.

Coal and coke are quiet, and sales are comparatively few, prices, however, being very steady.

Shipping is quiet, and the exports of both pig iron and steel are very small. Freights are low.

## THE SHEFFIELD DISTRICT.

(*From our own Correspondent.*)

A STILL quieter tone pervades the colliery districts this week. The Scotch strike has helped to some extent in tiding over a dull period. The fine weather, on the other hand, has reduced requirements most materially. The proposed reduction of 10 per cent., even with the concessions of a minimum wage at 30 per cent. over 1888 prices, is not quite cordially received by the miners, who have been taught too well the simple formula of "No reduction." It is generally believed, however, that the miners will accept the minimum wage offered to them by the coalowners. If this arrangement should be carried out there is no doubt it would influence the trade to a large extent. House coal is in less demand owing to the causes stated. The London market is not taking such large quantities as was reported a few weeks ago. Quotations are as under:—Silkstones, 9s. 6d. to 11s. per ton; Barnsley house, from 9s. to 10s. per ton; other qualities from 1s. to 1s. 6d. less. The demands for steam coal still continue good, and fetch reliable prices. Barnsley hards unchanged at 7s. 9d. to 8s. 6d. per ton; inferior qualities, 7s. per ton. Manufacturing fuel is dull, and prices are low, being very plentiful at 4s. 6d. to 5s. 6d. per ton. Smudge and small coal in good request at 2s. per ton. Coke quiet and easy to buy at 9s. 6d. to 11s. per ton. An extraordinary weight of coal is at present to be seen on the lines in nearly all the station sidings.

Hematites remain at the same prices as reported last week, namely, from 51s. to 52s. 6d., delivered in Sheffield; ordinary iron sheets £8 10s.; Bessemer billets, £5 7s. 6d. to £5 10s.; bar iron £5 10s. to £5 15s., and common forge iron 38s. The iron trade is excessively quiet. A similar remark applies to marine and railway material, the outlook in shipping circles being exceedingly gloomy. An order from a southern company for wagons has been locally placed, but work is exceptionally scarce all round, and many hands are unemployed, both in the heavy and light trades. The values of local companies on the Stock Exchange lists faithfully reflect the prevailing depression.

The battle of projectiles *versus* plates has received new interest from the reports of the experiments with the Russian shells. It is stated that although great secrecy was observed with regard to the Russian projectile, the Sheffield representatives present at the trials are satisfied that they know how the shell is made. They believe that the only means at present to resist the Russian shell is to use thicker armour. The new Harveyed armour is only two-thirds of the thickness of the plates previously employed to obtain the same degree of resistance. There is thus left a margin of one-third the thickness and weight of the armour before it would be necessary to go beyond the thickness used in the compound plates prior to the Harvey process being adopted.

The annual report of the Yorkshire Miners' Association for the year ending December 31st, 1893, has just been distributed to the various lodges. It exhibits how powerful this great trades union of colliers has now become. The total receipts for the year were £129,087 18s. 5d., which, added to the amount in hand—£163,825 12s. 2½d.—makes up a grand total of £292,913 10s. 7½d. The largest item of expenditure is under the head of "Contributions and donations to Miners' Federation of Great Britain," £22,438 13s. 4d. The salaries of paid officials include £514 19s. 8d., the amount received by Mr. Benjamin Pickard, M.P., secretary. The total expenditure for the year was £268,757 6s. 11d., leaving a balance of £24,156 3s. 8½d., of which £10,508 is the value of the offices and institutions at Barnsley, Leeds, Parkgate, and Hoyland. The Yorkshire Miners' Association numbers 55,000 members, which is precisely the same number as at the end of 1893. There are now very few miners in South Yorkshire who are not members of the Association.

There is no change whatever to report in the lighter staple trades of cutlery, plated goods, or edge tools. Several local firms are busy in the latter class of goods.

On Tuesday, the 24th inst., Mr. Benjamin Pickard, M.P., President of the Miners' Federation of Great Britain, is to be presented with a testimonial from the miners, in recognition of his services during the strike of last year, and the prolonged negotiations which resulted in the settlement. The testimonial, which has been wholly subscribed by working miners, members of the Federation, is to take the form of an illuminated album, accompanied by a cheque for a considerable sum of money, the exact amount of which has not transpired. The presentation will be made by Mr. J. Haslam, of Derbyshire, Chairman of the Sub-Committee.

The Great Northern Railway Company has just completed several new third-class dining carriages for the East Coast service between King's Cross and Edinburgh. These cars, which are built of teak and varnished, are 52ft. 6in. long, and 9ft. wide, with a canopy roof 8ft. 2in. high in the centre. They run on two four-wheeled bogies, with eliptic and bearing springs which are nicely regulated to secure smooth riding. Their outward appearance at once takes the eye through the novelty of their construction, the sides being thrown out to a curved line instead of being perpendicular, as in all other coaches. The effect is handsome, and the curving of the car gives additional room for an extra passenger at one of the sides. The cars hold forty-two passengers instead of twenty-eight, as in the older patterns. They are beautifully fitted with every accessory for the comfort of third-class passengers. On Thursday afternoon a trial trip was made to Lincoln and back with a train in which were two of these dining cars and a third-class saloon carriage, the three coaches having just been turned out of the carriage department of the Great Northern Railway at Doncaster, under the direction and superintendence of Mr. Stirling, the able chief of the locomotive works there. The coaches rode beautifully, not the slightest oscillation being perceptible, although the speed obtained varied from fifty-five to sixty miles an hour. The carriages are fitted with the Gold system of heating apparatus, with regulators so that the temperature can be raised or lowered as desired when the winter season sets in. Although there is seating accommodation for forty-two passengers, the car can be divided into three separate compartments if necessary. There are fourteen dining tables in each car; every passenger has ample room and abundant accommodation for newspapers, books, &c. Over each table is a net rack for holding hats, small hand-bags, &c., and attached to the side is a bottle and cruet to each table, while the car is well supplied with hooks for coats and other garments. The cars are well lighted with six compressed oil-gas chandeliers with steatite burners, giving a powerful and effective incandescent mushroom light. The floor is covered with extra-thick "kork" matting of carpet pattern, with an addition of another "kork" border, running the whole length of the gangway from the tables. The matting is very soft and noiseless to walk upon. The ventilation is maintained by means of the torpedo ventilators, which have been found in practice to work satisfactorily.

## THE NORTH OF ENGLAND.

(*From our own Correspondent.*)

THE dulness in trade in this district is unrelieved, on the contrary it grows greater, being intensified by the strikes which are in progress. The Scotch miners' strike, which was expected to cause a spurt in this district, and considerably better prices, has failed to produce either, because the stoppage of the pig iron consuming works in Scotland is much more complete than was looked for, and the requirements across the Border are comparatively small, so that there has been less sent than even last month, when there was no strike. It is true that nearly all the Scotch blast furnaces are idle again, and native pig iron is scarce outside the warrant stores, but the consumption as well as the production has been reduced, seeing that nearly all the mills and forges have been stopped. The iron that is now being taken by Scotch consumers is nearly all of foundry quality, as it is only the foundries that are kept going. The average for this month of the pig iron sent from the Tees to Grangemouth is considerably below that of the past half-year; it has only been a little over 1000 tons daily, whereas the average for the last six months was 1400 tons. And yet the expectation was that the deliveries would have been larger when the strike commenced. There seems to be an idea general now that the Scotch strike will last but a short time longer, and then it is thought that prices will decline further, nothwithstanding that the occurrence of the strike has not had any influence in raising prices; on the contrary, it has not prevented a fall, and to-day No. 3 Cleveland pig iron is the only description of iron that has not recently declined in value. Trade is very adversely affected also by the strikes of moulders and pattern-makers in this district. These are pretty nearly paralysing operations at a number of the finished iron and steel works, for they have led to the closing of a considerable number of shipyards, the proprietors of which cannot at present accept delivery of the plates, angles, &c., they have contracted to receive, and specifications are not forthcoming. Manufacturers have plenty of orders booked, but as they cannot proceed with the execution of them, they are compelled to look elsewhere for contracts, and in this they are not very successful, though they have generally reduced their prices. These operations are very irregularly carried on at our mills and forges, and one of the largest of the iron and steel making establishments, which is chiefly employed on orders from the shipbuilders, is expected to be closed in a few days, though there are plenty of orders on the books of the firm, which, however, cannot be proceeded with. Scotch shipbuilders are not doing much in the way of buying from North-country steel-making firms, though their own native works are closed on account of the miners' strike. It was thought that the extra business done on Scotch account would have more than counterbalanced the los caused by the local strikes, but such is not the case, and the situation is most unsatisfactory.

It is to be regretted that after enduring for seventeen weeks the strikes of moulders and patternmakers should be apparently no nearer a settlement than at first, and should still continue to paralyse so many other branches of trade. Not more than 1500 moulders, &c., are concerned in the dispute, but their action throws at least other 16,000 men out of employment, and what is more, the bulk of these must be out for seven or eight weeks longer, even if the strike were settled at once, because the other work is so far in advance of that of the moulders. The men continue to urge that the improved state of trade justifies their claim for advanced wages, yet the report of their own society describes trade as good in only three places, whereas at sixty-two places it is reported to be bad, and very bad. Something ought to be done to bring about a termination of a dispute which is disastrous to so many branches of trade other than that immediately concerned. Mr. Christopher Furness, M.P. for the Hartlepools, has make a suggestion to the masters and men that the dispute should be referred to arbitration, and that Sir Albert Rollitt, M.P., the Chairman of the Associated Chambers of Commerce and of the London Chamber of Commerce, should be selected as arbitrator. As yet there is no reply from either side.

Pig iron, except No. 3 Cleveland, is this week being offered at lower prices than ruled last week, but the demand for No. 3 is fairly well maintained, and the supply at least in makers' hands is hardly equal to the requirements; in fact, shippers in many cases complain of the difficulties they often experience in making up the cargoes of their vessels through the inability of the makers to load them promptly. Not less than 35s. 6d. is now accepted for prompt f.o.b. deliveries of No. 3 Cleveland G.M.B. pig iron. Cleveland warrants move very little, and the business in them is very disappointing, especially to speculative holders. The price all the week has been in the neighbourhood of 35s. 6d. cash. The stock of Cleveland pig iron in Connal's warrant stores on Wednesday night was 98,704 tons, or 673 tons increase this month. No. 4 Cleveland foundry pig is at 34s. 6d., and grey forge at 34s.; and consumption is decreasing because of the irregular working of so many finished ironworks, owing to the moulders' strike. Mixed numbers of East Coast hematite pig iron have fallen in value, and can be bought at 43s. 3d. per ton, the decline during the last few weeks being at least half a crown. Rubio ore is cheaper, 12s. 1½d. per ton delivered on the Tees being accepted for an average ore, this reduction being due to a fall in freights. The exports of pig iron from Middlesbrough this month to Wednesday were 54,213 tons, against 49,778 tons last month, and 46,130 tons in July, 1893, all to 18th.

The Cleveland blast furnacemen appear determined to take a twenty-four hours' holiday in order to hold a demonstration in favour of the adoption of the eight hours' shift at the furnaces, and they have practically fixed Saturday, August 11th, as the date of their holiday. The employers at a conference with the men's representatives, held at Middlesbrough, protested strongly against this proposed holiday, but they intimated that if the men persisted in their intention they would offer no further opposition, and will not require the usual legal notices to be lodged. They, however, state that the stoppage will involve very far-reaching and serious loss. Fully £10,000 would be sacrificed in wages in the North of England as a result of that day's stoppage alone; but the loss in wages incidental to and consequent upon preparing the furnaces for a stoppage, will more than double this. The employers themselves will be heavy losers. The holding of the demonstration will not, the masters say, weaken their opposition to the eight hours; the grounds for which they are fully prepared to discuss with the men or their representatives. They are convinced that the adoption of the eight hours will increase the cost of making iron, and that is not to be thought of at the present time.

The death has occurred this week of Mr. Edward Robson, who has for many years been connected with the Cleveland iron trade. The deceased, who was a native of Darlington, commenced his business career under Messrs. Pease and Partners, and he subsequently became commercial manager for Messrs. Bell Brothers, at Port Clarence. He was afterwards in Wales, and leaving there he became connected with Mr. Thomas Vaughan, the partners opening out the Woodhouse Close Colliery. They also work and worked successfully the Cragg's Hall Ironstone Mine, near Skinningrove. In association with the late Mr. George Wythes and Mr. Henry Cochrane, the deceased opened out other Cleveland mines, including those at Strongbow and Kilton. He also owned the Cassop, Tyne Main, and Victoria Collieries, and subsequently took a lease of the Dunsdale Mines, after which he founded the firm of Robson, Maynard, and Co., who built the Redcar Ironworks. From this firm he retired in 1880, and the works have since been carried on by the remaining partners under the style of Walker, Maynard, and Co. Latterly Mr. Robson was agent for Mr. Walter Scott's collieries at Trindon Grange, for the Forcett Limestone Co., and for Messrs. Dunford and Elliot, of Newcastle and Middlesbrough. The death is also reported of Mr. Joseph Bond, who for many years was engineer at the Tow Law and Tudhoe blast furnaces for the Weardale Iron and Coal Company, but for the last twelve years he has carried on a steel foundry at Tow Law, where he was well known for the manufacture of tub wheels and general colliery castings.

The manufacturers of finished iron and steel have generally had to reduce their prices, because they have been obliged to seek orders to take place of those the execution of which has to be postponed on account of the closing of so many shipyards. Steel ship-plates can be bought at £4 17s. 6d.; steel angles at £4 12s. 6d.; iron ship-plates at £4 15s.; iron angles, £4 12s. 6d.; and common iron bars at £4 17s. 6d., all less 2½ per cent. and f.o.t. Heavy steel rails are nominally £3 12s. 6d. net at works.

The coal trade is in a fairly brisk condition, there being an improved business on export account, and the better prices are maintained. Collieries generally are working well, except in the house coal trade. Best Northumberland steam coal realises 11s. per ton, and small 5s. f.o.b., while gas coal is 7s. 3d. per ton f.o.b. Blast furnace coke of good quality can be had at 12s. 3d. per ton.

## NOTES FROM SCOTLAND.

(*From our own Correspondent.*)

THERE is very little to notice in connection with the iron trade this week, business being completely suspended in the Glasgow district by the fair holidays and much interrupted elsewhere by the miners' strike.

The Glasgow pig iron market was closed from Thursday to Tuesday. On its re-opening business was done in Scotch warrants at 41s. 9½d. cash, and in Middlesbrough hematite at 42s. 9d., these prices indicating a decline of 1½d. to 2d. per ton. There is no speculative interest whatever in the market, operators having apparently made up their minds to have nothing to do with business in the meantime.

Special brands of makers' iron have been advancing in price, owing to their scarcity and the stoppage of production. G.M.B. f.o.b. at Glasgow No. 1 is quoted 43s. 6d.; No. 3, 42s. 6d. per ton; Monkland No. 1, 46s.; No. 3, 42s. 6d.; Carnbroe No. 1, 45s. 6d.; No. 3, 44s. 6d.; Clyde No. 1, 51s. 6d.; No. 3, 48s. 6d.; Calder and Summerlee No. 1, 53s. 6d.; No. 3, 48s. 6d.; Gartsherrie No. 1, 55s. 6d.; No. 3, 49s.; Coltness No. 1, 57s. 6d.; No. 3, 51s.; Glengarnock at Ardrossan No. 1, 52s.; No. 3, 48s. 6d.; Eglinton No. 1, 49s.; No. 3, 45s.; Dalmellington at Ayr No. 1, 47s.; No. 3, 45s.; Shotts at Leith No. 3, 51s.

The output of hematite pig iron is entirely suspended, and there are only fourteen furnaces producing ordinary and special brands compared with twenty-three last week. The Glengarnock Company has placed four furnaces on basic iron. The total furnaces of all kinds now blowing in Scotland is eighteen, of which there are three at Coltness, four at Shotts, two at Ardeer, five at Summerlee, and four at Glengarnock. The following ironworks are altogether stopped:—Dalmellington, Eglinton, Clyde, Gartsherrie, Carnbroe, Wishaw, Langloan, Carron, Calder, Govan, and Monkland. The ironmasters are resolved not to pay higher prices for coals, and they will keep their works idle until the strike is at an end.

The shipments of pig iron from Scottish ports in the past week amounted to 5932 tons, against 4107 in the corresponding week of last year. The steel works are all closed, and are expected to continue so till the strike is over. It is rumoured that one or two of them may not reopen again. Since the beginning of the year there has been a spell of activity at the steel works, but in a majority of cases no profits have been made, owing to heavy costs and extreme competition, and the business is therefore of a heartless description.

The finished ironworks are closed, and the market is practically idle for the time.

The shipments of iron and steel manufactured goods from Glasgow in the past week embraced locomotives worth £2000; sewing machines, £7957; other machinery, £4000; steel goods, £4050; and miscellaneous iron goods, £12,100.

There has been a further decrease in the coal shipments, the total for the week, coastwise and foreign, having been only 21,052 tons, against 24,849 in the preceding week, and 145,948 in the corresponding week of last year. A peculiarity of the present crisis is that there is no demand for coal for any purpose whatever. Consumers have tacitly made up their minds to keep out of the market, and although large quantities of coals are on offer from England, they cannot at present find a market.

The leaders of the miners have been quarrelling as to matters of policy, and the men are dissatisfied with the strike allowance. They have now been out four weeks, and all the money they have got in the West of Scotland for that period is from 3s. 8d. to 5s. per man. The Fife miners have managed to secure about twice as much by excluding non-unionists from the distribution, and this has caused a great deal of ill-feeling.

## WALES AND ADJOINING COUNTIES.

(*From our own Correspondent.*)

THE great event, upon which all interest centres, is the Albion inquest, which was reopened on Monday at Pontypridd before two coroners, Mr. Reece, Cardiff, and Mr. Rhys, Aberdare. Mr. Roskill attended from the Home-office, and there was a numerous array of counsel, mine inspectors, mining agents, and representatives of the Albion Company. Plans of the pit were exhibited. Both shafts are 19ft. in diameter; the depth of the downcast is 545 yards to the landing, and the extreme depth 580 yards. The surveyor, in exhibiting the plans, was questioned by Mr. Roskill as to the arrangements for watering the mine. Grover's level was damped by means of a pipe, and leakages from pipes, also by water from old workings.

Mr. Philip Jones, certificated manager of the colliery, stated that his experience included forty-three years underground. For seven years he had been manager of the Albion. Mr. Jones gave a full description of the mine. Questioned about shot-firing, witness stated that dynamite and roburite were used, and generally in blasting out timber the practice was to bore a hole with an auger, 3ft. from the ground, and fill it with about 2 oz. of dynamite. He had heard on the Thursday after the explosion that Wm. Austley had received orders from John Evans, the night overman, to prepare a shot on the double parting on the Cilfynydd side, between the night and day shifts, on the day of the explosion. Monday's evidence ended with the examination of the record books, showing that no gas had been met with for five or six months before the explosion. On Tuesday the examination of the manager was protracted. He gave a full description of the mine immediately after the explosion. He was then questioned by coroner and Mr. Roskill; 286 bodies had been recovered. In the course of the examination it was stated by him that a very heavy fall of rock top had taken place on the Cilfynydd side. There was a 10ft. cavity in the roof of the intake where the solid rock was blown down. Minute questioning took place as to this cavity, shot firing, the latest firing on the day of the explosion, mode of watering, flame following the explosion of dynamite, care of lamps, &c., and there was elicited the manager's impression that the starting place of the explosion was at the fall referred to, and that this, driving down the gas, it had been swept onwards to the naked lights called "comets" on the off side of the lamp station, and the first explosion followed. This was only given as a surmise. In the examination which followed, and was continued on Wednesday, it was evident that the subject is being grappled ably, and that certain good will follow, in better security for the future, even if direct evidence as to cause is not forthcoming.

There is a good deal of vigour in the coal trade, and exports of steam coal are well maintained. Last week over 300,000 tons were sent from the Cardiff ports alone. Prices too, I find, are kept up well, yet I note that here and there it is nothing unusual for the colliers to lose a "turn," and so it is not at all unlikely that we are not far away from the temporary slackness, which comes in fittingly, at a time when coalowners and brokers take the annual run to the seaside and other pleasure resorts. The quotations in Cardiff this week compared well with last week:—Best steam, 12s. 3d. to 12s. 6d.; seconds, 11s. 6d.; dry qualities, 10s. 6d. to 10s. 9d.; best small, 6s. 3d. to 6s. 6d. House coal has shown no change, best is selling at 10s. 9d. to 11s. 3d.; No. 3 Rhondda, 10s. 9d. to 11s.; brush, 9s. to 9s. 6d.; small, 7s. to 7s. 6d.; No. 2 Rhondda, 10s. to 10s. 3d.; through, 7s. 3d. to 7s. 6d.; small, 5s.

Swansea prices:—Best steam, 10s. to 11s. 6d.; seconds, 9s. 6d. to 10s.; anthracite, from 8s. 9d. to 12s. 6d., according to quality.

Swansea coal exports keep up well, and it is estimated that, judging from the trade of the first half of '94, the year will show an increase of 350,000 to 400,000 tons. From Newport, again, the totals are very satisfactory. Foreign coal shipments for the six months ending June show an increase of 376,350 tons, or 41·33 per cent. The large increase at Newport is being accounted for by the diversion of the Powell-Duffryn coal, yet I am glad to add that Cardiff shows no falling off.

In the Caerphilly Valley capital work is being done at Llanbradach, and already an average total of 500 tons daily is being raised from No. 1 pit. It is expected that an output from No. 2 will begin this month. At the "Universal," Aber, both pits are down 150 yards, and already a township is being formed. It is estimated that this colliery will support 5000 persons.

Patent fuel continues in good demand at Cardiff and Swansea. Cardiff, 10s. 9d. to 11s. 3d.; Swansea, 10s. to 10s. 9d. Last week Swansea sent 1955 tons to France, 1600 tons to Russia, 4850 tons to Italy, and 2910 tons to Algeria. Coke at Cardiff is a little weaker, furnace selling from 15s. 6d. to 16s. 6d.; and foundry, 17s. to 18s. Pitwood prices have an upward tendency.

Prospects in the iron and steel trade are more favourable; and ironmasters with good stocks of ore, and a tranquil labour market, are in a good position to meet a large demand. Rails, steel bars, pig, and small goods continue to be the principal things in request. Crop ends are also in demand, and merchant bars. Steel bar make at Cyfarthfa continues active; and for the new manufacture, bricks, the requirement of buyers is greater than can be met—600 tons of rails from the district went to Christiansand last week.

At Briton Ferry the output of pig continues large, and that of steel bars quite up to the average. Sixteen mills are now busily at work, and outlook is encouraging. At Swansea there was a certain amount of depression in pig, and in Glasgow warrants prices are 4d. less than last week, quotations being 41s. 9½d.; Middlesbrough and hematite are better, the former in good demand; hematite warrants, 43s. 8d. for mixed numbers. Other quotations are:—Welsh bars, £5; steel rails, heavy, £3 15s. to £4; light, £4 7s. 6d. to £4 10s.; steel sheets are better, £6 to £6 5s.; iron, £5 15s. to £6 10s. Bessemer steel: tin-plate bars, £4; Siemens, best, £4 2s. 6d. to £4 5s., all delivered in the district; cash, less 2½. Block tin is at £67 5s. to £67 7s. 6d.; this is indicating a drooping condition.

Tin-plates show an improvement in shipments but not in price, and the element of uncertainty keeps business down to short and immediate deliveries. A condition of expectancy is to be noticed, and any day good bookings forward and better figures may come in to relieve the monotony. The autumn is likely to see a marked change, so runs the impression amongst merchants.

On 'Change at Swansea this week the following quotations remained:—Steel coke, 10s. 3d. to 10s. 4½d.; Siemens, 10s. 4½d. to 10s. 7d.; best charcoal, 11s. 6d. to 12s. 6d.; ternes, 19s. to 23s. The shipments last week amounted to 69,456 boxes; receipts from works, 57,317 boxes; present stock at Swansea, 277,106 boxes.

Swansea imported last week 1040 tons pig, 419 tons tin bar, and exported 35,527 tons of coal.

Information has been received on 'Change from America that the new tariff will not come into force until October.

At a hauliers' meeting held in Aberdare, on Saturday, it was stated that the difference at Plymouth collieries had been satisfactory arranged. The hauliers' agent, Mr. Morgan Thomas, made overtures to the meeting to join the Union. The aim, he stated, was to lessen the hours of labour, and secure regular wages of at least 5s. a day. At the close it was agreed to call a general meeting of hauliers on the first Monday in August, and discuss the subject.

The Ammanford men, numbering about 300, are out on strike, the dispute being for a re-adjustment of prices, consequent upon the "pillar and stall" method being exchanged for the "long wall."

An important meeting of colliery representatives—men—has been held at Merthyr a few days ago, when a resolution was passed embodying the opinion of the conference, that only by the employment of sub-inspectors chosen from amongst colliers, and paid by Government, could the lives of the colliers be properly safeguarded. This opinion is to find prompt expression in the House of Commons, and to be reiterated until something is done.

A locomotive boiler explosion took place near Rhymney Ironworks, lately: driver and stoker escaped without injury, but the engine was wrecked.

A working collier has invented an apparatus to show that coal dust cannot originate an explosion. It is stated that he has not quite perfected it, but is confident of doing so.

The Taff Vale Railway records an increased revenue for last week of £837, and the Brecon and Merthyr and Swansea Bay and Rhondda are also improving.

The annual report of the Tredegar Iron, Steel, and Coal Company has been issued, and notwithstanding the stoppage of the iron and steel works, a profit of £20,550 12s. 11d. is shown.

The coal output last year exceeded by 120,000 tons that of the preceding year. The collieries are reported to be in a state of highest efficiency, and sinkings to the deep at the Pochin pits are to be shortly undertaken. The report comments on the continuance of an unsatisfactory state of the iron and steel trades, and no hint is given of a restart, as lately rumoured.

## NOTES FROM GERMANY.

(*From our own Correspondent.*)

THE continental iron market remains quiet, scarcely any business of importance having been transacted upon the week. The demand on foreign account has been particularly dull for some time past, and there is generally but little firmness noticeable in quotations.

Iron and steel trade in Silesia continues very languid, only a small volume of business being done. Orders for export are especially scarce; the home demand is also limited, and the works would be but very poorly occupied if it was not for some good orders formerly booked, which secure pretty regular employment for at least several weeks to come. For the few orders that are offering at present, very low prices have to be quoted; although list rates are nominally the same as in former weeks, makers are practically getting less than if list prices had been officially reduced, because they have to grant substantial concessions in almost every instance.

Good accounts are still given of the iron trade in Austria-Hungary. Prices are firm and even rising, and a satisfactory activity is reported all round. The different sorts of pig iron meet with ready demand, and there is quite a lively tone noticeable in the finished iron department, most articles, with the exception of bars and sectional iron, having been briskly called for.

The steel trade is rather quiet just now, very few orders for railway requirements being given out. The hardware business has slightly improved, especially that done on local account, and a further increase in demand is expected within the course of next month.

Iron business in France shows pretty much the same tendency as during former weeks, prices being firm and demand satisfactory, although there has perhaps been a quieter tone in the pig iron market this week than last, and less speculative business. A fair trade is doing on foreign, chiefly colonial account, which naturally has a stiffening effect on prices in general.

The unsatisfactory condition of the Belgian iron trade, that has so long been reported, still exists, and a despondent feeling prevails all round. Prices have reached the very lowest point, plates being the only article that has shown a trifle more firmness lately, owing to a slight improvement in demand. Girders are in irregular request and prices fluctuating, producers having, in a few instances, obtained rather better prices, while the majority of makers still complain of the utterly weak tone that continues to characterise this branch of the malleable iron trade.

Returns for the first five months of the present year show exports in steel to have increased 14,000 t. against the corresponding period last year. Pig iron also shows a slight increase.

Concerning the business done on the Belgian coal market during the first five months of the present year, the import of coal appears to have decreased 10,000 t. against last year; being 557,240 t. this year, against 567,875 t. in the previous year. The import from Germany shows an increase of 20,000 t., while that from England has decreased 30,000 t. The import in coke from Germany to Belgium was 24,000 t. higher this year than last, the total import in coke to Belgium amounting to 127,110 t., against 101,241 t. for the corresponding period last year. Export in coal during the first five months of the present year only shows a slight decrease of 27,000 t., the total export in coal having been 1,674,086 t., against 1,701,373 t. for the same period last year. Export of Belgian coke to France shows a decrease of 30,000 t.; to Luxemburg, 16,000 t.; the total export in coke amounting to 369,525 t., against 399,043 t. for the corresponding period last year.

Although but a quiet sort of business has been transacted on the Rhenish-Westphalian iron market for some weeks past, the general tendency is yet not without firmness, and there is much hopefulness expressed with regard to autumn business, which is expected to make up for the somewhat sluggish trade that has been done in spring and early summer. For the present but few inquiries are coming in on the pig iron market; prices are, however, tolerably well maintained for almost all sorts. Stocks do not show a change since previous letters; if anything a slight decrease has to be reported here and there. In manufactured iron a steady business has been doing all through last week. Bars have been improving in demand, and there is certainly less reserve practised by local dealers, who apparently wish to replenish their stocks now, when makers are most anxious to sell their articles, and, consequently, agree to pretty large concessions. There is little animation noticeable in girders now that the best part of the building season is nearly over and most orders have been disposed of. Hoops are in regular demand, and the fact that contracts have already been secured for the fourth quarter shows that further reductions in prices are not expected on the part of buyers. Plates and sheets are rather brisk of sale, but remain weak in quotation. Home requirements for drawn wire are still exceedingly small, but there is a fair demand coming forward on foreign account; prices remain, without exception, very low. Both foundries and machine factories are reported to be but irregularly employed, and the activity at the locomotive shops is also decidedly insufficient.

The collieries of the Saar district have produced in June of present year 529,000 t., consumption amounting to 500,340 t.; in June last year output of coal was 450,915 t., while 432,255 t. were slod.

Statistics regarding the Rusian foreign trade during the first quarter of present year show value of export to have been 143,270,000 roubles, against 83,819,000 roubles for the corresponding period last year, while value of import was 81,754,000 roubles, against 62,530,000 roubles for the same period last year.

The export of machines from Switzerland is stated to have been considerably higher in 1893 than during the year before. There were exported in boilers, 794 tons, against 602 tons in 1892; dynamo-electric machines, 1046 t., against 751 t.; constructions in iron, bridges, &c., 14 t., against 184 t.; agricultural machines, 184 t., against 268 t. in the year 1892; flour milling machinery, 3132 t., against 2452 t.; sewing machines, 18 t., against 25 t.; weaving machines, 4534 t., against 4136 t.; spinning engines, 1292 t., against 851 t.; embroidering machines, 618 t., against 544 t.; knitting machines, 46 t., against 45 t.; bicycles, 5, against 5 last year; different sorts of machines, 6827 t., against 5634 t.; in all, 18,510 t., against 15,727 t. in the previous year.

## AMERICAN NOTES.

(*From our own Correspondent.*)

NEW YORK, July 12th, 1894.

THE strikers, the decline in the volume of business, shrinking of bank clearings, refusal of merchants to place usual autumn orders, and a feeling of general disquiet have had a most depressing effect on manufacturing and commercial interests. The iron trade is on the eve of a moderate improvement, but prices are low, and manufacturers are not, therefore, soliciting late deliveries. Pig iron production is increasing. Twenty furnaces have blown in during the week, six bar iron mills have resumed, and quite a number of smaller concerns. There are inquiries for 50,000 tons steel billets, of which about one-fourth are wanted for eastern delivery during the next four months, but manufacturers are holding too high. The placing of some important bridge iron contracts have been postponed until August. Barb wire, wire rods, nails, and sheet iron are all moving briskly in Western markets, except at Chicago, but to a strictly local trade, shipments by rail being absolutely suspended. The country was in good shape for an upward trade movement when the railroaders' strike was precipitated. With no stocks on hand in any branch, buyers of long experience feel apprehensive of an upward movement. Such things are not new in American markets. But an advance could only be temporary. The long restriction has been a surprise to manufacturers generally. Forge iron has been offered at 10 dols. delivered, and No. 1 foundry at 12 dols., not taken. There can be no movement until the present strike is over. Coal mining has been only partially resumed, and three or four regions have gone out again.

## LAUNCHES AND TRIAL TRIPS.

RECENTLY there was launched from the shipyard of Messrs. John Scott and Co., at Kinghorn, a steel screw steamer, built for the special trade of Messrs. Wilson, Hart, and Co., of Maryborough, Queensland. The dimensions of the vessel are 165ft. by 25ft. 6in. by 11ft. 9in., and has raised quarter-deck, bridge-house and top-gallant forecastle. She is built to class 100 A1 at Lloyd's special survey, and has triple engines to indicate about 500-horse power, with an extra large boiler working at 170 lb. per square inch. The christening was performed by Mrs. Robert Hart, who named the vessel Queensland, and wished her goodluck. The vessel was launched with steam up, and on leaving the ways proceeded to adjust compasses and run the trial trip.

The Geneva Cross, which has been built to the order of the Metropolitan Asylums Board for the purpose of conveying patients from the Board's various wharfs in London to the small-pox hospital ships at Long Reach, was taken to the measured mile on the Thames on the 4th inst., in order that her official speed trials might be made. The result of six runs, with and against the tide alternately, showed that a mean speed of over 15 knots was realised. Further continuous speed trials were made on the Thames on the 13th inst. in order to ascertain the working capabilities of the ship and engines. Both of these trials were satisfactory, and were made in the presence of several of the managers of the Metropolitan Asylums Board, who expressed their entire satisfaction with the vessel and her machinery. She has been built and engined by Messrs. John Stewart and Son, Blackwall. The principal dimensions of the boat are as follows: Length over all, 143ft.; breadth, 22ft.: draught of water, 5ft. The machinery consists of a pair of compound diagonal surface-condensing engines, having cylinders 23in. and 46in. respectively with 42in. stroke, developing over 700 indicated horse-power. The boilers, which are two in number and of the cylindrical multitubular type, constructed of steel to Board of Trade requirements, are each 9ft. 6in. in diameter and 10ft. long, with a working pressure of 120 lb. per square inch. The hull of the vessel is divided into five water-tight compartments by means of four transverse bulkheads, and is also of steel throughout. At the forward end of the vessel the crew are berthed, abaft this there is ample accommodation for fully forty visitors who may be desirous of visiting their friends at Long Reach and are sufficiently convalescent to see them. The machinery space comes next, after which the entire after part of the ship is devoted to hospital accommodation. It will be seen, therefore, that the visitors' saloon is entirely isolated from the hospitals. The hospitals are two in number, the upper and lower, and are each divided in a suitable manner in order to separate the male from the female patients. Accommodation is provided for fifty-two recumbent patients, together with nurses' rooms, reception room, sinks, linen cupboards, w.c.'s., and all other fittings necessary for a vessel of this description. Great care has been observed in securing ample ventilation, as also with regard to the heating arrangements throughout the vessel; indeed, she could, if so desired, be used as a floating hospital. Spacious cabins on the upper deck are also provided for the doctor and captain. She is fitted with Davies and Co.'s steam steering gear amidships, also a powerful hand gear aft. A complete electric light installation is fitted by Messrs. J. H. Holmes and Co., Newcastle-on-Tyne. The vessel has been designed and constructed under the personal superintendence of Mr. John Hudson, naval architect and engineer, of 47, Leadenhall-street, and of Mr. C. Thomson, M.I.N.A., the superintendent of the river ambulance service.

## THE PATENT JOURNAL.

*Condensed from "The Illustrated Official Journal of Patents."*

### Application for Letters Patent.

*** When patents have been "communicated" the name and address of the communicating party are printed in italics.

*4th July*, 1894.

12,950. Securing Windows, C. D. Fisher and F. F. Turner, Birmingham.
12,951. Child's Chairs, W. S. McLennan and T. Morton, Glasgow.
12,952. Speed Meter, O. Petterson, London.
12,953. Pneumatic Tires, A. E. Smith, Manchester.
12,954. Waterproof Ventilating Cloth, V. Hendricks, Manchester.
12,955. Portable Cases and Maps, G. A. Macbeth, London.
12,956. Motive Power Production, S. Shiel, Swineford, Co. Mayo.
12,957. Ironing Machines, E. Taylor, jun., Manchester.
12,958. Heating and Ventilating Radiators, J. Keith, Glasgow.
12,959. Ball Cocks, F. Caulfield, Glasgow.
12,960. Regenerative Gas Lamps, W. H. I. Welch, London.
12,961. Wood-planing Machines, T., R., and W. Lees, jun., Manchester.
12,962. Crocheting Machines, J. Köhler, Manchester.
12,963. Selvedge Motion for Looms, H. Harrison and H. Shackleton, London.
12,964. Tube Manufacture, R. Wootton and F. H. Griffiths, Birmingham.
12,965 Switching Electric Currents, G. B. Blanchard and A. Ballance, London.
12,966. Laying Dust in Coal Mines, A. Ross, Manchester.
12,967. Cycloramas, G. Newnes and H. C. Watson, London.
12,968. Refrigerator for Meat and Fish, J. Gillings, London.
12,969. Ball Bearings for Cycles, G. Gibson, Newcastle-on-Tyne.
12,970. Gravy Spoons, A. J. Boult.—(*G. Bay, France.*)
12,971. Gas Engines, H. A. Humphrey, Liverpool.
12,972. Arc Lamps, S. Doubrava and J. Donát, Manchester.
12,973. Casting Electric Accumulator Plates, C. Hampel, Liverpool.
12,974 Air Compressors, La Compagnie de Fives-Lille London.
12,975. Brushes, W. P. Thompson.—(*E. Doernberger, Germany.*)
12,976. Photographic Camera Shutters, E. Pickard, Manchester.
12,977. Bicycles, J. Fineberg and J. Clayton, Liverpool.
12,978. Albumenised Paper, R. Münch, London.
12,979. Looms, S. Braun and M. Schweitzer, London.
12,980. Artificial Musk, C. D. Abel.—(*Fabriques de Produits Chimiques de Thann et Mulhouse, Germany.*)
12,981. Rolls of Perforated Paper, C. A. P. F. Tschofen, London.
12,982. Electric Arc Lamps, J. Brockie, London.
12,983. Appliance for Holding Cigars, H. Salsbury, London.
12,984. Coats, R. Skelton, London.
12,985. Feathers, T. C. Palmer, London.
12,986. Driving Mechanism for Cycles, R. Piwowarski and R. Bularski, London.
12,987. Chemical Compounds, H. E. Newton.—(*The Farbenfabriken vormals Friedrich Bayer and Co., Germany.*)
12,988. Ankle Supporting Appliance, J. S. Marshall, London.
12,989. Perpetual Calendar, F. J. Waite and M. Simon, London.
12,990. Convertible Tables, T. Alsopp and R. Brown, London.
12,991. Electrical Cooking Appliances, J. A. Macmeikan, London.
12,992. Candlesticks, E. G. Godfrey, London.
12,993. Electrolytic Separation of Gold, A. Cruickshank, London.
12,994. Spice or Condiment Receptacle, A. Schierholz, London.
12,995. Ladders, P. Schmahl, London.
12,996. Fastening for Skirts, E. M. Jackman, London.
12,997. Making Sheets of Wired Glass, G. F. Chance and Chance Brothers, London
12,998. Appliance for Descending a Rope, W. Barret, London.
12,999. Ladies' Dress Pockets, S. Joseph, London.
13,000. Plaquet Holes of Dresses, S. Joseph, London.
13,001. Starting Vehicles, C. Guattari, London.
13,002. Multiple-barrel Guns, B. H. Thwaite, London.
13,003. Food-preparations, H. H. Lake.—(*F. Delangle, France.*)
13,004. Binding Medium for Size Colours, J. Clasen, London.

*5th July*, 1894.

13,005. Syringe Applicable to Fire-hose, W. B. Press London.
13,006. Wool-washing Machines, F. G. Sargent, London.
13,007. Portable Excavating Machine, C. R. Scoles, Canada.
13,008. Railway and Tramway Rails, J. Forsyth, Gateshead.
13,009. Machine for Washing Bottles, W. Ogilvie, Dublin.
13,010. Harrow, J. S. Coates, Co. Wicklow,
13,011. Canvas Tubing for Bicycle Tires, A. Drummond, Guildford.
13 012. Laminated Springs, R. R. Eadon and J. Beatty, Sheffield.
13,013. Covers or Envelopes for Letters, W. Junge, London.
13,014. Monument, C. Downing, Barnsley.
13,015. Letter-copying Books, R. J., T., and E. P. Rowe, Bradford.
13 016. Yarn for Hearth-rugs and Mats, E. Wilkins, Morecambe.
13,017. Process of Decorating Pottery, P. Shelley, Longton.
13,018. Electrical Firing Keys, &c., H. V. Keeson, London.
13,019. Toys, J. Walker, Birmingham.
13,020. Anchors, T. H. W. Beddoes and G. A Newall, Bristol.
13,021. Out-of-door Seats, W. Baker, Bristol.
13,022. Gas Meters, T. Thorp, T. G. Marsh, and J. Haynes, Manchester.
13,023. Automatic Stopping Cock, J. R. Cock, Bristol.
13,024. Heel-burnishing Machines, W. H. Dorman, Stafford.
13 025. Stoppering Bottles, W. H. Wheeler, Birmingham.
13,026. Cases for Ribbons, C. Marx, Manchester.
13,027. Rollers for Wringing, J. Livingston and W. Gibson, Manchester.
13,028. Clip for Attaching Wagons, J. Gill, Wakefield.
13,029. Furnaces for Burning Sludge, S. J. Beaman and J. Deas, Manchestor.
13,030. Lubricator Lifter, J. L. C. Knowles and N. Ellison, Manchester.
13,031. Preservation of Food, H. J. C. Paulsen, Manchester.
13,032. Hinges, R. Wootton and F. H. Griffiths, Birmingham.
13,033. Sheep Dipping Apparatus, R. S. and T. C. Fletcher, London.
13,034. Felt Hat Body Planking Machines, H. H. and A. Turner, Manchester.
13,035. Animal Traps, J. B. D. Brander, Liverpool.
13,036. Suspender for Overcoats, H. J. Trautmann, and F. Stahl, Liverpool.
13,037. Bobbin Holders, W. P. Thompson.—(*J. D. Aiken, United States.*)
13,038. Wrought Iron, J. Lakin and C. H. Page, London.
13,039. Game and Apparatus therefor, H. N. Morgan, London.
13,040. Overflow Fittings for Basins, J. J. Wilson, Glasgow.
13,041. Sinkers for Knitting Frames, C. A. Roscher, Berlin.
13,042. Electric Current Switch, G. B. Blanchard and A. Ballance, London.
13,043. Strainer for Tea and Coffee Pots, F. Mann, London.
13,044. Oil Cans, S. C. N. White, London.
13,045. Indicating Names of Stations, G. W. Robertson, W. S. Page, and C. E. Vernon, London.
13 046. Weighing Scales or Balances, R. Doughty, London.
13,047. Scoring in Billiards, &c, W. Smetham, London.
13,048. Steel, J. Bedford, London.
13,049. Gearing for Lathes, A. E. Hodder and W. Goodacre, London.
13 050. Stop-cocks, J. C. McNabb, London.
13 051. Gymnastic Apparatus, W. Niedieck, London.
13 052. Fasteners for Paper and Cloth, A. Combault, London.
13 053. Cooling Refrigerating Machines, J. Gamgee, London.
13,054. Levigating or Grinding Machinery, A. Maw, London.
13,055. Filters for Water Taps, &c., J. Harvey, Manchester.
13,056. Pedal for Propelling Bicycles, W. P. Jencks, London.
13,057. Butter Making Apparatus, J. H. H. Duncan, London.
13 058. Needle for Combing Machines, G. Fromm and J. Roll, London.
13,059. Multiple Drilling Machines, F. Zinzen, London.
13,060. Life-saving Apparatus, T. Tufnell, Hong Kong.
13,061. Movement of Shuttle-boxes, J. Serre and F. Rostagnat, Twickenham.
13 062. Brackets for Curtain Poles, H. J. Haddan.—(*T. H. Klein, United States.*)
13 063. Indicating Lamp Failures, G. J. T. J. Parfitt, London.
13,064. Fastener for Gloves, &c, C. Hüttemeister, London.
13,065. Frames for Sash Windows, J. A. Glazier, London.
13,066. Plates for Engraving and Etching, J. W. Swan, London.
13,067. Dipping Sheep, A. Blackie and E. A. White, London.
13,068. Paper-feeding Mechanism, G. C. Blickensderfer, London.
13,069. Using Disinfecting Substances, J. H. Starling, London.
13,070. Self-loading Fire-arm, The Eisenwerke Gaggenau Actien-gesellschaft, London.
13,071. Draught Excluder for Doors, W. White, London.
13,072. Nozzles for Syringes, &c., M. W. O'Reilly, London.
13,073. Rotary Pumps, S. M. Cockburn and H. E. Montgomery, London.
13,074. Disinfecting Water-closets, S. Radlauer, London.
13,075. Extension Ladders, P. Schmahl, London.

*6th July*, 1894.

13,076. Tin Opening Knives, C. A. Dainesi, London.
13,077. Flour Sifter, D. McKenzie, London.
13,078. Switch for Lowering Lamps, E. R. Cummins, London.
13,079. Constructing Framework of Furniture, J. Saunders, Liverpool.
13,080. Gear for Hydraulic Valves, G. B. Sharples, Manchester.
13,081. Coin-freed Photograph Machines, P. Mushet, Glasgow.
13,082. Erecting Telegraphic, &c., Wires, C. Shore, Rochdale.
13,083. Crank Pins and Journals, T. S. James, London.
13,084. Pressure Gauge for Tires, T. S. James, London.

13,131. Manufacture of Blank Cartridges, O. Brzostowicz, London.
13,132. Feed Bag for Horses, L. M. Thudichum.—(*T. P. Terry, United States.*)
13,133. Railway Signalling Apparatus, A. Gregory, London.
13,134. Handles for Heated Objects, W. H. Beck.—(*W. F. Greene, United States.*)
13,135. Purifying, &c, Rain-water, R. Pringle, London.
13,136. Submarine Telegraph Cables, H. A. Taylor and J. A. L. Dearlove, London.
13,137. Multiple Wheel and Hand Stretcher Ambulance, J. J. A. V. C. Raye, Banbury.
13,138. Bearings, F. E. Thormeyer, London.
13 139. Films Imitating Mother-of-pearl, S. Hahn, London.
13,140. Bobbins of Ring Spinning Machines, G. F. Ruttloff and B. R. Dietrich, London.
13,141. Flexible Driving Shafts, J. Y. Johnson.—(*C. J. Fravega and A. Janet, France.*)
13,142. Air Pumps, R. F. Hall, London.
13,143. Machinery for Rolling Rims of Wheels, R. F. Hall, London.
13,144. Supporting Attachment for Bicycles, G. H. Fortune, London.
13,145. Luminous Paint, L. E. Josset, London.
13,146. Lighting of Tunnels, &c., A. G. White, London.
13,147. Gauge for Carpenters, &c., C. Bainbridge, London.
13,148. Electrical Measuring Instruments, H. T. Harrison, London.
13,149. Billiard Cues, W. H. D'Oyly, London.
13,150. Hand Fire-extinguishers, C. B. Murray, London.
13,151. Automatic Closing Devices for Tap-holes, J. C. Steele, London.
13,152. Utilising the Force of Waves, T. M. S. English, London.
13,153. Purification of Alcohol, E. Hermite, E. J. Paterson, and C. F. Cooper, London.
13,154. Washing Fabrics, O. Imray.—(*H. Treichler, Switzerland.*)
13,155. Systematic Washing of Impure Sugar, O. Imray.—(*R. Folsche, Germany.*)
13,156. Manufacture of Naphthylendiamine Sulpho Acids, C. D. Abel.—(*A. Fischesser and Co., Germany.*)
13,157. Insulating Electric Cables, G. E. Heyl, London.
13,158. Electric Fuses, G. E. Heyl, London.
13,159. Window Fasteners, A. W. Dadson, London.
13,160. Electric Cables, G. G. M. Hardingham.—(*Felten and Guilleaume, Germany.*)

*7th July*, 1894.

13,161 Slotted Shackle, &c., for Weighing Purposes, T. Cheshire, Liverpool.
13,162. Rife-barrel Coolers, H. Bates, Birmingham.
13,163. Automatic Closing Safety Receiving Box, E. Cadman, London.
13,164. Cutting Mechanism for Rotary Printing Machines, C. J. Watkins, Dublin.
13,165. Portable Vessels for Liquids, T. H. Case, London.
13,166. Steam Traps, W. Shore and G. E. Coupe, Manchester.
13,167. Collecting Refuse, M. Ingram and A. F. Morrison, Manchester.
13,168. Radiators for Oil Stoves, H. V. Rippingille, London.
13,169 Ball Bearings, C. H. Sims and E. Sykes, Halifax.
13,170. Ambulance Shells for Hospitals, T. Lloyd, London.
13,171. Treatment of Towns' Refuse, F. W. Lacey, Bournemouth.
13,172. Gear for Cycles, W. D. Bohm and J. Sander, London.
13,173. Preparing Cotton, J. W. Scott and J. Parkinson, London.
13,174. Connecting Buckles to Ladies' Belts, J. Bird, Penarth.
13,175. Bib Taps, T. G. Dowson, London.
13,176. Machines for Finishing Hat Moulds, R. Wallwork, Manchester.
13,177. Gravity Railway, W. T. A. Emtage, Nottingham.
13,178. Food for Cattle, A. M. Millot, London.
13,179. Ferrules for Walking Sticks, F. Lodge, Bradford.
13,180. Gas Engines or Motors, T. G. Normanton, Barrow-in-Furness.
13,181. Syphon Cisterns, G. Brindley, J. McEwen, and S. Thompson, Manchester.
13,182. Electric Light Ceiling Roses, C. Richardson and E. Herbert, Manchester.
13,183. Oil-cans, S. Johnson, London.
13,184. Making Steel, T. Hampton, Sheffield.
13,185. Stoppering Bottles, W. H. Baines, Sheffield.
13,186. Class Desk, J. J. D. Paul and G. Dannock, Norwich.
13,187. Box for Displaying Velvet, &c., J. Wright, Manchester.
13,188. Winding Machines, B. and F. A Holt, Manchester.
13,189. Slubbing and Roving Frames, T. F. Dunn, Manchester.
13 190. Bicycle Lock, J. Power, Manchester.
13,191. Corset Fasteners, H. H. Leigh.—(*R. Hinrichsen, Germany.*)
13,192. Digging Machines, T. C Darby, London.
13,193. Producing Photographs in Colours, H. A. Fardell, London.
13,194. Refrigerating Liquid, M. Wanner, London.
13,195. Tanning Skins and Hides, T. H. L. Bake and H. A. Leverett, London.
13,196. Photographing in Colours, J. Joly, London.
13,197. Candlesticks, J. Fraser, Liverpool.
13,198. Treatment of Waste Materials, J. H. Lester, Manchester.
13,199. Metallic Phosphate Compounds, C. Raspe, Liverpool.
13,200 Fittings for Band-boxes, &c., E. A. Cole, London.
13,201. Box-nailing Machines, W. S. Doig, London.
13,202. Manufacture of White Lead, H. Wilcox, London.
13,203. Making Acids, C. D. Abel.—(*A. Fischesser and Co., Germany.*)
13,204. Level Surface Hinge, W. Veitch, Kansas City, U.S.A.
13,205. Making Knitted Vests, J. H. Woodward, London.
13,206. Heaters for Curling Irons, F. J. Gascoigne, London.
13,207. Brakes, W. H. Beck.—(*The Fox Safety Block and Signal Company,* ———)
13,208. Dynamos, W. H. and R. W. Allen and C. C. Hawkins, London.
13,209. Glue-pots, W. Keeble, London.
13,210. Printing Textile Fabrics, H. W. Sanderson, London.
13,211. Device for Billiard Tables, J. F. Marshall, London.
13,212. Horseshoes, L. Grünfelder and E. Hauviller, London.
13,213. Lamp Bracket for Cycles, A. Davey, Manchester.
13,214. Adjusting Pictures, J. H. and A. H. R. Major, London.
13,215. Appliances for Holding Papers, E. Drechsler, London.

*9th July*, 1894.

13,216. Magnetic Separator, W. H. and J. I. Ryder, Birmingham.
13,217. Tents and Marquees, &c, W. Hatchman, London.
13,218. Wine and other Bottles, &c, H. I. Ingham, Leeds.
13,219. Skates for Use on Roads, R. J. Stanley, Bristol.
13,220. Golf Iron, A. L. Goodall, Derby.
13,221. Condensing Exhaust Steam, B. H. Thwaite, London.
13,222. Advertising Device, A. S. Ford and H. Tulloch, London.
13,223. Displaying Advertisements, S. Bunting, Birmingham.
13,224. Twiners, H. Bayley, Son, and Co., and W. Swindells, Manchester.
13 225. Coin-counting and Indicating, E. A. Brown, Keighley.
13,226. Railway Safety Appliance, J. Bennett, Burton-on-Trent.
13,227. Screw-conveying Windlass, J. Bennett, Burton-on-Trent.
13,228. Lock and Latch Staples, &c., J. Taylor, Willenhall.
13,229. Rabbit Traps, J. N. Lester and H. Lavender, Walsall.
13,230. Cycle and Carriage Tires, J. Wilson, Manchester.
13,231. Shafting Bearings and Hangers, J. Caygill, Bradford.
13,232. Device for Sharpening Knives, H. F. Chope, London.
13,233. Fastening for Gates and Doors, J. E. Morton, Peterborough.
13,234. Friction Clutch, T. Metcalfe and W. Ambler, Bradford.
13,235. Grain Drying Apparatus, W. Holland, Birmingham.
13,236. Reducing Carriage Vibration, S. H. Stubbs, Manchester.
13,237. Stop Motion for Hay Elevators, T. W. Cook, Yaxley.
13,238. Velocipedes, S. Humber and F. Edwards, Nottingham.
13,239. Excentric Ball Cock, J. Templeton, Dublin.
13 240. Springs for Seats of Furniture, J. W. Drury, Eastbourne.
13,241. Mechanical Stokers, W. D. Grimshaw, Manchester.
13,242. Securing Pedals, W. Bown and J. H. Hughes, Birmingham.
13,243. Atmospheric Gas Burners, G. E. Wright, Birmingham.
13,244. Railway and other Couplings, F. Seeger, Liverpool.
13,245. Fastening for Axle-boxes, L. Hagmeyer, Liverpool.
13,246. Picture Books, H. Munslow, London.
13,247. Reflectors for Street Lamps, W. P. Brown, Manchester.
13,248. Golf Handles or Shafts, &c., F. Bryan, London.
13,249. Joints for Earthenware Pipes, J. Farley, London.
13,250. Stone Breaking Machinery, G. Lowry, London.
13,251. Cases for Needles and Pins, E. Johnson, Birmingham.
13,252 Cigar and Cigarette Holders, J. Favets, London.
13,253. Game, M. Cole, London.
13,254. Direct-acting Pumping Engine, G. de Laval, London.
13,255. Hat Fastener for Ladies' Hats, A. C. Herts, London.
13,256. Explosives, T., S. H., and H. Hawkins, London.
13,257. Applying Power to Vehicles, F. O'C. Prince, London.
13,258. Wave Mills, C S. Snell, Saltash.
13,259. Automatic Electric Exchange, R. Pippette, London.
13 260. Prussiates, O. Imray.—(*Goerlich and Wichmann, Germany.*)
13,261. Disinfection, W. Rowbotham and M. P. Dickson, Manchester.
13,262. Welding Metals, A. V. Newton.—(*A. Nobel, France.*)
13,263. Lubricators, A. Mills, London
13,264. Preserving Paintings, H. Rangeley and F. J. Butcher, London.
13,265. Lamps, W. Perkins, London.
13,266. Lamp Wick, W. Perkins, London.
13,267. Galvanometers, J. Hopkinson, London.
13,268. Paper and Card Suspender, S. H. Crocker, London.
13,269. Traps for Flies and Insects, T. Klussmann, London.
13,270. Steam Boilers, H. Lane and J. Pullman, London.
13,271. Billiard Cue and Tip, &c., T. J. L. Box, London.
13,272. School Calculating Apparatus, E. Scholler, London.
13,273. Lasts and Trees for Boots, H. T. Brockwell, London.
13,274. Hat Press, W. J. Fallon and H. P. Onslow, London.
13,275. Support for Curtain Rods, C. E. Bulling, London.
13,276. Match Igniting Composition, H. Priester, London.
13,277. Typewriter, F. von Eulenfeld, London.
13,278. Loom and other Shuttles, J. W. Champion, London.
13,279. Belts, Braces, Garters, &c, W. Rothschild, London.
13,280. Armour-plates, H. H. Lake.—(*E. M. Fox, United States.*)
13,281. Regulating Temperatures, F. N. Mackay, London.
13,282. Securing the Ends of Boot Laces, A. Hecht, London.
13,283. Purifying Water, R. Haddan.—(*C. J. Leroy,* ———.)
13,284. Fire-escapes, V. Hembacher, London.
13,285. Jacks, J. Silbereisen, London.
13,286. Apparatus for Stopping Horses, C. Pack, London.
13,287. Marking Lawn Tennis Courts, W. Jackson, London.

*10th July*, 1894.

13,288. Combined Clock and Calendar, T. Slaiter, London.
13,289. Piece Boards, Sir T. Salt, Sons, and Co. and H. H. Spencer, Bradford.
13,290. Blowing Glass, H. B. Barlow.—(*J. J. Power, United States.*)
13,291. Wickets for Playing Cricket, J. C. Shaw, Manchester.
13,292. Water-closets, T. W. Twyford, Birmingham.
13,293. Connecting Earthenware, T. W. Twyford, Birmingham.
13,294. Folding Seats and Chairs, &c., A. Plant, Glasgow.
13,295. Applying Ball Bearings, J. T. Fenwick, London.
13,296. Goffering or Creasing Machine, H. Trotman, London.
13,297. Magetta, H. Jonas, Edinburgh.
13,298. Gas and Oil Motor Engines, &c., S. Griffin, Bath.
13,299. Fuel, J. B. Taylor, Bath.
13,300. Weldless Chain Links, G. Stevenson, Glasgow.
13,301. Dumb Caddie, Earl of Wemyss and March, Glasgow.
13,302. Smoke Cowls and Ventilators, H. Miller, Glasgow.

13,303. Pumping Engines, E. de Pass.—(*The G. F. Blake Manufacturing Company, United States*)
13,304. Spring Clip for the Waist, H. T. Hallam, Birmingham.
13,305. Kite, M. Wattleworth, M. A. Mason, and J. M. Brindle, Manchester.
13,306. Combined Brush and Liquid Spray, J. Y. Duckworth, Huddersfield.
13,307. Refuse Destructors, W. Radcliffe, Huddersfield.
13,308. Brace Fittings, A. Breese, London.
13,309. Line Drier for Fishing-rod Lines, G. Grey, Northumberland.
13,310. Pessary, J. C. Conolly and L. Strong, Dublin.
13 311. Fastenings for Field Gates, F. P. Potter, King's Lynn.
13.312. Ball Bearings, C. H. Sims and E. Sykes, Halifax.
13,313. Machine for Making Hexagon Nuts, H. and F. Bennett, Staffordshire.
13,314. Propelling Bicycles, A. R. Sawyer, Newcastle-on-Tyne.
13,315. Manufacture of Ammonia, W. McD. Mackey and J. F. Hutchinson, Leeds.
13,316. Receptacles for Tobacco Ashes, M. Vernon, Birmingham.
13,317. Burners for Oil Lamps, G. H. Middleton, Birmingham.
13,318. Wood-working Machines, J. M. Burke, Liverpool.
13,319. Electric Arc Lamps, P. Kirkegaard, Manchester.
13,320. Roll Turning Machine, G. Vine, London.
13,321. Hand Bag, E. Lycett. Birmingham.
13,322. Sweeping Machines, H. Groeger, London.
13,323. Starting, &c., Tramcars, &c., J. Rawlings, London.
13,324. Pessary with Disinfecting Receptacle, F. W. Golby.—(*Weissgerber, Germany.*)
13,325. Boring Tool, F. W. Golby.—(*W. Knispel, H. Schott, and H. Otto, Germany.*)
13,326. Attaching Flowers to Dresses, E. Tyrrell and J. A. Riley, London.
13,327. Window Brackets, F. R. Martin, London.
13,328. Kilns for Drying Bricks, &c., J. Onions, London.
13,329. Cycle Bosses, T. Middlemore, J. Beesley, and C. Rossiter, London.
13,330. Valves for Heating Coils, G. Ashwell and D. M. Nesbit, London.
13,331. Electrically-controlled Lubricating Device, L. W. de Grave, Derby.
13,332. Wood and Iron Girder, H. Moldenhauer and P. Seidig, London.
13,333. Gas Engines, G. C. Marks.—(*F. Hirsch, United States.*)
13,334. Casement Stay and Hook, A. T. Fitchew, Ramsgate.
13,335. Gas-burners, F. Reiset, London.
13,336. Pedo-locomotive Machine, L. Armanni, London.
13,337. Dies, A. J. Bradley, London.
13,338. Water Heater, V. I. Feeny.—(*Parke and Lacy Company, United States.*)
13,339. Edging Machines, E. Cornely and R. Cornely, London.
13,340. Hair-clipping Machine, V. I. Feeny.—(*C. Greene, United States.*)
13,341. Tongue-cleaner Attachment for Tooth-brushes, Will and Finck Company and M. Fredrick, London.
13,342. Joints for Wires, T. C. Batchelor, London.
13,343. Shuttle Swell, T. A. Leigh.—(*J. Bannister, Mexico.*)
13,344. Pins or Fasteners, J. E. Needham, Liverpool.
13,345. Textile Fabrics, W. P. Thompson.—(*P. C. D. Castle, Germany*)
13,346. Dental Chairs, W. P. Thompson.—(*D. Stuck, United States.*)
13,347. Horseshoes, W. P. Thompson.—(*H. H. Gibbs, United States*)
13,348. Rotating Devices for Rock Drills, P. A. Newton.—(*The Ingersoll-Sergeant Drill Company, United States.*)
13,349. Time-stamp Motors, J. S. McCoy, London.
13,350. Artificial Horizon, H. A. Gadsden, London.
13,351. Type-setting Apparatus, W. H. Beck.—(*L. K. Johnston and A. A. Low, United States*)
13,352. Pneumatic Tires, E. Peverall and S. Roberts, London.
13,353. Calculating Rules, M. J. B. P. Laurand, London.
13,354. Flanged Dutch Tiles, &c., M. Harczyk, London.
13,355. Ball Bearings for Heavy Loads, P. Davies, London.
13,356. Egg Beaters, A. J. Saltsman and E. E. Howe, London.
13,357. Ferrule-making Machines, W. Cannell, London.
13,358. Electrolysis, H. H. Lake.—(*I. L. Roberts, United States*)
13,359. An Instantaneous Water Heater, W. Tallett, London.
13,360. An Improved Clock, W. Jerger, London.
13,361. A Human Nail Trimmer, F. J. Mockler, London.
13,362. Galloway Boilers, C. J. Galloway, London.
13,363. Plate for Voltaic Batteries, W. A. B. Buckland, London.
13,364. Apparatus for Preparing Wort, C. Rach, London.
13 365. Incandescent Gas Burner, C. H. M. H. Delamarre, London.
13 366. New or Improved Pipe Cleaner, P. Elford, London.
13,367. Hat Pins, T. H. Slater and H. Brooks, London.
13,368. Roses for Watering Cans, &c., C. Sachs, London.
13,369. Clarifying Glue, &c., P. C. Hewitt, London.
13,370. Stringed Instruments, B. E. Woollenhaupt, London.
13,371. Switches for Pneumatic Tubes, C. M. Johnson, London.
13,372. Specimens of Natural History, S. F. Denton, London.
13,373. Cycles, W. Foss, London.
13,374. Device for Making-up Bouquets, C. W. Titterington, London.
13,375. Boot and Shoe Fastenings, J. A. Bown, London.
13,376. A New or Improved Toy, J. C. Macnab, London.
13,377. Treating Salt, P. Jensen.—(*H. C. F. Störmer, Norway.*)
13,378. Mounting Speed Gears, P. L. Renouf and F. Westwood, Birmingham.
13,379. Preparing Bristles for Brushmaking, A. S. Miles, London.
13,380. Dough-dividing Apparatus, A. Mohr, London.
13,381. Oil Engines, H. Cook, London.
13,382. Combined Bricks and Tiles, W. F. de Morgan, London.

*11th July*, 1894.

13,383. Syphon Cisterns, J. E. Rogers, Birmingham.
13,384. Method of Drawing-off Liquids, C. Witz, Germany.
13,385. Generating Combustible Gas, B. H. Thwaite, London.
13 386. Cranks for Cycles, G. Pirnie, Dundee.
13,387. Stone-sawing Machinery, G. Anderson, Dundee.
13,388. Grates for Steam-boiler Furnaces, E. C. Mills, Manchester.
13,389. Flyers of Spinning Machinery, J. Macortney and W. J. Larkin, Glasgow.
13,390. Smoke-consuming Apparatus, J. Hutton, sen., Sheffield.
13,391. Metal Boot Protectors, W. Freeman, Leicester.
13,392. Skirt and Blouse Fastener, E. E. Cox, Birmingham.
13,393. Cycle Tires, A. and E. Normanton, Manchester.
13,394. Windows, M. L. Puzey, New Barnet.
13,395. Ventilating Sewers, J. T. Neech, Manchester.
13,396. The Combination Collar and Tie, J., J., and G. R. Bevins, Leicester.
13,397. Carding Engines, W. Lord and W. Rhodes, Manchester.
13,398. Golf Clubs, A. G. Hogg, Manchester.
13,399. Spinning Machinery, &c., S. Thompson, Manchester.
13,400. Hydraulic Motor, Sir W. Arrol and W. Foulis, Glasgow.
13,401. Prevention of Down-draughts, C. Hitchcock, London.
13,402. Manufacture of Street Lamps, A. M. Wade, Birmingham.
13,403 Pivot Hoe Land Cleaner, &c., T. Jamieson, Aberdeen.
13,404. Flushing Apparatus, A. and J. Tutcher, Bristol.
13,405. Induction Coils, A. Cheetham and F. Brown, Birmingham.
13,406. Brushes, W. Pritchard, Sheffield.
13,407. File Handles, H. S. Havenhand, Sheffield.
13,408. Repairing Pneumatic Tires, W. and H. Guest, Sheffield.
13 409. Heating Boiler Feed-water, T. Sykes, Manchester.
13,410. Electrical Switches, C. M. Dorman and R. A. Smith, Manchester.
13,411. Biscuit Boxes, J. Collins, Glasgow.
13,412. Chair Money-box Puzzle, R. Stubbert, Liverpool.
13,413. Street Vehicles Driven by Motors, J. Adam, Liverpool.
13,414. Colouring Tanned Hides by Smoke, A. Herrmann, Liverpool.
13,415. Roller Trawl Ports, R. E. Ellis and A. Kay, Leith.
13,416. Continuous Electric Brakes, A. Young, Edinburgh.
13,417. Overalls for Workmen, W. G. and J. B. Leatherbarrow, Manchester.
13,418. Combination Windows, H. B. Jones, Manchester.
13,419. Incandescent Gas Lamp, &c., C. Schinz, London.
13,420. Fastening Device for Drawers, K. Haupt, Liverpool.
13,421. Valves for Hydraulic Apparatus, W. James, London.
13,422. Electric Relays, W. P. Thompson.—(*C. E. Maréchal, P. C. H. Rigollet, and the Société E. Ducretet and L. Lejeune, France.*)
13,423. Buckle for Braces or Suspenders, J. S. Römpler, London.
13,424. Pumping Engines, J. G. Barclay, Glasgow.
13,425. Filling Ginger Beer, &c., Bottles, J. Bullen, London.

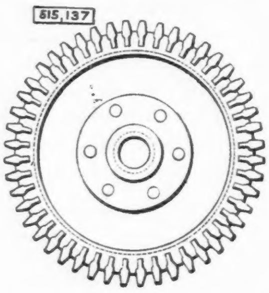
## SELECTED AMERICAN PATENTS.

*From the United States Patent Office Official Gazette.*

**515,137.** Gear-wheel and Method of Making same, *C. E. Beck, Allegheny, Pa.—Filed August 9th*, 1893.

*Claim.*—(1) The method of manufacturing gear-wheels, consisting in inserting teeth in a mould, placing a paper composition in the mould, and compressing the same about the teeth, whereby they are firmly embedded in the wheel body, substantially as described. (2) The method of manufacturing gear-wheels, consisting in inserting teeth in a mould, placing a stiffening plate therein, and compressing the paper composition about the teeth and plate, substantially as described. (3) The method of manufacturing gear-wheels, consisting in inserting separate teeth in recesses of the mould, placing a paper composition in the mould, and compressing the same about the teeth, whereby they are firmly embedded in the wheel body, substantially as described.

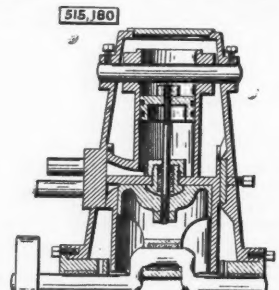
515,137



**515,180.** Oscillating Steam Engine, *E. E. P. Truesdell, Belvidere, Ill.—Filed September 22nd*, 1893.

*Claim.*—(1) In an oscillating steam engine, the combination of a suitable casing, a crank shaft, high and low-pressure cylinders arranged tandem having a pivotal connection with the casing, a steam supply port for the high-pressure cylinder, an exhaust port for the low-pressure cylinder, a port connecting the two cylinders, and pistons for each cylinder having a connection with the crank shaft. (2) In an oscillating steam engine, the combination of a suitable casing, a crank shaft, high and low-pressure cylinders having a pivotal connection with the casing and having a centre partition provided with a stuffing-box, the opposite ends of the cylinders being open, a piston for each cylinder having a piston-rod connection and a connection with the crank shaft, a steam supply support for the high-pressure cylinder, an exhaust port for the low-pressure cylinder, and a port connecting the two cylinders. (3) In an oscillating steam engine, the combination of a suitable casing, a crank shaft, high and low-pressure cylinders provided with ports on one side, the casing provided with a steam supply port, a steam exhaust port, and a port forming a communication between the high and low-pressure cylinders, a piston for each cylinder having a connection with the crank shaft.

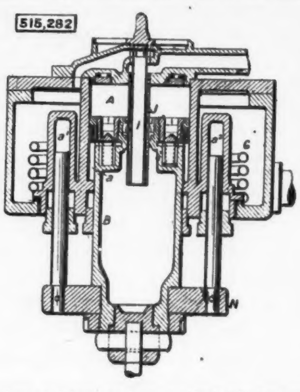
515,180



**515,282.** Air Compressor, *P. Brotherhood, London, England.—Filed October 18th*, 1893.

*Claim.*—(1) In an air compressor, the combination of the cylinder A having an annularly valved cover, the trunk piston B connected to a reciprocating cross-head N and having through it valved passages into the annular space *a* around the trunk, several smaller cylinders $a^1$ $a^2$ having plungers attached to the cross-head N and valved passages, from the space *a* to them, and valved passages from them to a pipe coil G, the water tank H and the concentric pipes I and J, substantially as and for the purposes set forth.

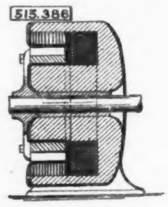
515,282



**515,386.** Dynamo-electric Machine, *J. Wenström, Orebro, Sweden.—Filed March 6th*, 1893.

*Claim.*—In a dynamo-electric machine, the combination with the two poles of a field magnet, of an armature attached to one of said poles and having a continuous uninterrupted surface adjacent to the air gap, and a keeper of solid magnetic material, revolving in the air gap between the said armature and the other pole, substantially as described.

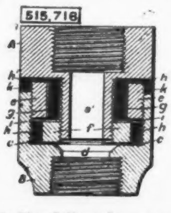
515,386



**515,716.** Insulated Pipe Coupling, *G. Peeples, Philadelphia, Pa.—Filed June 5th*, 1893.

*Claim.*—(1) The combination in an insulated coupling, of the upper section, a threaded neck thereon, a ring adapted to such threaded neck, the lower section, a threaded ring adapted thereto, and insulating material provided between the meeting faces of the rings, and the meeting faces of the rings with the sections, substantially as specified. (2) The combination of the section A, having a threaded neck *a′*, a ring *f*, adapted thereto, the lower section B, having an internally threaded portion *d*, a ring *e* adapted thereto, insulating rings *g* and *h*, located between the rings and the adjacent faces of the opposite sections, and insulating rings *c*, *i*, and *h′* located between the rings *e* and *f* and the sections A and B, substantially as specified. (3) The combination of the section A having a threaded neck *a′*, a ring *f*, secured thereto, the lower section B the ring *e* secured thereto, and rings of insulating material, *c*, *g*, *h*, *h′* *i*, and *k*, disposed between the rings *e* and *f*, and the sections to which they are secured, substantially as and in the manner set forth.

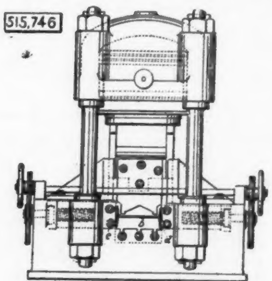
515,716



**515,746.** Machine for Cutting Sections of Metallic Beams, *M. H. Cameron and W. Snape, Salford, England.—Filed July 18th*, 1893.

*Claim.*—(1) In combination, the pair of bottom knives *b b′* arranged opposite each other with a space between, the pair of opposing knives *c c′* arranged at one end of the knives *b b′*, and the pair of opposing knives *d d′* arranged at the other end of the knives *b b′*, said pairs *c c′*—*d d′* forming side cutters, and the shear blade *a* arranged to enter the space between the pairs of knives, substantially as described. (2) In combination, the pairs of bottom knives *b b′* arranged opposite each other with a space between, the pair of opposing side knives *c c′* at one end of the knives *b b′*, the pair of opposing side knives *d d′* at the other end of the bottom knives *b b′*, the means for adjusting the side knives lengthwise of the bottom knives, and the shear blade *a* arranged to enter the space between the pair of knives, substantially as described. (3) In combination, the opposing bottom knives *b b′*, the pairs of side knives *c c′ d d′* at the ends of the bottom knives, the means for adjusting each of the knives *c c′ d d′* independently and the shear blade *a* arranged to enter between the knives, substantially as described.

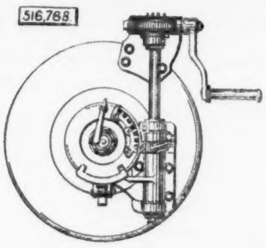
515,746



**515,768.** Feed-water Filter, *A. Harris, Middlesbrough, England.—Filed May 11th*, 1893.

*Claim.*—(1) In a filter an inclosing chamber provided with a removable cover, and having in its lower part a sludge chamber and outlet and a seat for filtering frames, in combination with a series of superimposed annular filtering frames, each clothed with upper and lower sheets of filtering material, said frames having passages at one side opening into the spaces between adjacent frames and passages at the opposite side communicating with the spaces between the filtering sheets of the individual frames, the passages at one side being connected with a fluid supply and those at the opposite side with an outlet passage, and means for clamping said frames together. (2) In a filter the combination of an inclosing casing provided with a removable cover, and having at its bottom a sludge outlet, a fluid outlet, and a seat for filtering frames, a series of outwardly inclining, or cone-shaped, superimposed annular frames each clothed with upper and lower sheets of filtering material, the interior chamber formed by the frames communicating with the fluid outlet of the casing, and a removable cap closing the top of said chamber, the said frames having openings between them connecting an exterior fluid passage, with the spaces between adjacent frames, and openings through their inner walls connecting the spaces between the filtering sheets of the individual frames with the said interior chamber and fluid outlet.

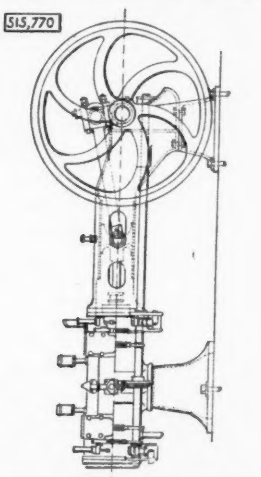
516,768



**515,770.** Gas Engine, *J. W. Hartley and J. Kerr, Kilmarnock, Scotland.—Filed March 9th*, 1893.

*Claim.*—In combination, the cylinder and piston, the two charge inlet valves, the single gas valve with branch pipes leading to both the charge inlet valves, the valve stems depending through their casings, the cam shaft extending under the valve stems to operate the same directly, the governor for the single gas valve located between the two charge inlet valves, the gearing for operating said governor directly, said gearing extending from the cam shaft, the ignition valves arranged on same side of the engine with the cam shaft and over the same, and having their stems actuated directly by cams on the cam shaft, the exhaust valves arranged on the opposite side of the engine from the cam shaft and inlet valves, and the levers extending from the cam shaft to the stems of the exhaust valves, substantially as described.

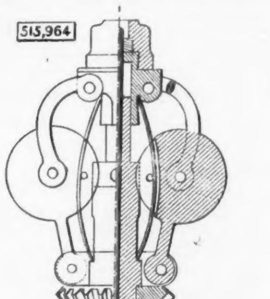
515,770



**515,964.** Steam Engine Governor, *S. P. Lathrop, Montclair, N.J.—Filed May 18th*, 1893.

*Claim.*—(1) In a governor having weights jointed both to a head upon the spindle and to a collar fitted movably to the same, the combination, with the head, the collar, and the weights, of a flat leaf spring held at its ends adjacent to the head and collar and bent transversely between its ends as the weight moves outward, as herein set forth. (2) In a governor having weights jointed both to a head upon the spindle and to a collar fitted movably to the same, the combination, with the head, the collar, and the weights, of spring fulcrum pins in opposite sides of the head, flat leaf springs fitted thereto and extended upon the inner sides of the weights to the sliding collar, and the pins *p* inserted through the weights to engage the middle of the spring, as set forth.

515,964



## THE INSTITUTION OF NAVAL ARCHITECTS.

The summer meeting of the Institution of Naval Architects is being held this year at Southampton, a town which, by all its associations and its considerable shipping trade, is admirably suitable. We have pointed out before now the great value of these summer excursions to the Institution, and so far they have fully justified all that we have said. Mr. Holmes, the secretary, is an admirable manager, and the cities visited have met the Institution more than half way. The Institution has now 1100 members, and is still growing in numbers and importance. As at Cardiff last year, so at Southampton this year, a very influential local committee has been formed, with the Mayor, Mr. W. Bone, as chairman, and a most efficient executive committee, of which Mr. Bone is also chairman. The hospitality of the people of Southampton has been unbounded, and a distinct advance has been made in the Cardiff proceedings in that two garden parties, one given on Wednesday by the Mayor, and the other, on Thursday, by Sir Steuart and Lady Macnaghten, to which ladies were invited, and an excursion round the Isle of Wight, on Friday, in the London and South-Western Railway Company's Jersey steamer, Frederica, was planned and carried out with special regard and consideration for ladies.

The proceedings began on Tuesday morning at 10.30 a.m. in the Hartley Institute, with a reception by the Mayor, the President of the Southampton Chamber of Commerce—Mr. T. Morgan—and the members of the reception committee. Afterwards, Lord Brassey took the chair. He delivered an introductory address.

Lord Brassey said he desired, on behalf of the Institution, to express to the Mayor and to the President of the Chamber of Commerce, as well as to the community of Southampton generally, represented by these gentlemen, their most sincere and warm acknowledgments of the kindness they were manifesting to the Institution on the occasion of its visit to Southampton. They would have, he knew from the programme, many hospitalities accorded to them in the course of the week, and, therefore, he should have many occasions to renew that expression of thanks which he now desired most heartily and sincerely to give. He much regretted that Mr. W. H. White was not able to be there. He was for the time obliged to take a rest, which was abundantly earned by his devoted service to the Navy of this country. Reviewing the recent progress in shipbuilding in this country, he said they were building ten battleships of the first class, two first-class and nine second-class cruisers, two sloops, and thirty-six torpedo boat Destroyers. These vessels were in addition to those completing under the Naval Defence Act. The new battleships were, as they were all aware, of unprecedented displacement. The increase of size had been necessary in order to add to the coal capacity, while retaining the armour protection and armament of their immediate predecessors. On the present occasion critical observations were entirely uncalled for; they would not come suitably from the president of the Institution, who had certainly not been selected for that office on the ground of technical qualification. If they admitted the necessity for increased dimensions, which had been adopted, it might confidently be affirmed that the new ships represent, and worthily represent, all that can be accomplished in the present state of naval science. While recognising the fighting power of the new ships, he might be permitted to speak not less approvingly of the Barfleur and the Centurion, as admirable examples of a small type of battleship. These ships give an excellent combination of all the elements of fighting capacity, and in speed showed a decided superiority over the larger ships. Comparisons were given showing the qualifications of different vessels, and reference was made to the increasing necessity for strengthening the torpedo flotilla both in numbers and efficiency. Being at Southampton, his lordship said it was proper to mention that some of the new boats had been entrusted to a firm in the immediate neighbourhood. In referring to Mr. John Samuel White, of East Cowes, it was almost unnecessary to remind them that that gentleman and his father had for several years been largely engaged in providing the Navy with steam and other boats. The firm deserved especial honour, as they all knew the remarkable evolutionary qualities displayed in the type, which was appropriately known as the turn-about. Reference was made as to the speed of these vessels; and Lord Brassey went on to speak of the mercantile marine, and was glad to be able to congratulate the Institution on the continued maintenance of the maritime supremacy of this country, which was largely due to their skill and enterprise. Their merchant navy had been advancing at a rate incomparably exceeding that achieved by any maritime rival. Unfortunately, the profits had not grown in proportion to the tonnage. Rarely had the returns to shipbuilders and investors in shipping been so unsatisfactory as in recent years, the fluctuations in the amount of building had borne no relation to the demands for freight. He expressed the opinion that sailing ships should not be allowed to disappear. He spoke not only under the inspiration of sentiment, because it seemed on the strictest economic grounds desirable that the cheap power of the wind should be utilised under all suitable conditions. A comparison was drawn as to the advantage of sailing ships over steamers, it being added that if the sailing fleet disappeared the best school of training for seamen would be lost, while the career of the sailor would certainly be deprived of much that was interesting and attractive. He pointed out that, taking the sailing ships of all sizes, British ships were distinctly better manned in relation to tonnage than either the German, Swedish, and Norwegian ships, and a careful investigation into the manning of steamers gave similar results. He alluded to the assistance he had received in preparing his statistics from Professor Biles, and went on to state that the Board of Trade returns showed the tonnage removed from the register of the United Kingdom on account of wrecks fell from 263,000 tons in 1883 to 163,000 in 1892. They had seen in what marvellous proportions the tonnage of their shipping had advanced. They saw in every port splendid examples of what the skill of the members of that Institution, and the splendid enterprise of their shipowners could produce, and it was a source of high satisfaction to know that, with the increased facilities of communication between nation and nation, greater safety had been secured. He then referred to the postal contracts, and the recent discussion at Ottawa. They had been able to dispense with the heavy expenditure incurred by other Powers in supplying mail services as auxiliaries to their navies. The general growth of tonnage under the British flag was sufficient to show that the assistance of the State was not greatly needed by the merchant service. When, however, they looked away from the main lines of trade to the opening of the new routes, aid might often be given with advantage; it was sometimes indispensable. The pleasure fleet should not be wholly omitted. They were meeting in the headquarters of the yachting fraternity. In the present year they had not seen that great cutter, the Meteor, sailed in former years in their own waters with such sportsmanlike spirit by the German Emperor. The Britannia, however, built by the Prince of Wales specially to promote a distinctive national sport, the Valkyrie, and the Satanita had been contending in many exciting matches. During the last few weeks the famous American champion, the Vigilant, had entered the lists. The Valkyrie had met with a disaster, but the Britannia had succeeded in scoring numerous victories. For the first time since the arrival in this country, in 1851, of the famous America, British designers and yachtsmen had been able to produce a champion capable of beating the American centre-board type. The power of sailing, and especially of beating into the wind's eye, which had been recently exhibited by British yachts, was truly remarkable. He knew that he was expressing the general sense of the members of the Institution when he said that Mr. Gould, as the owner of the Vigilant, might be assured that his visit to this country was most warmly welcomed.

HARBOUR AND DOCKS AT SOUTHAMPTON

The first paper read was by Mr. Dixon.

### On "The Harbour and Docks of Southampton."

The author began by sketching the history of Southampton, and went on at once to describe the modern works. The Harbour Board maintains two lightships; one, the "Itchen" light, at the mouth of the river Itchen, and near the southern extremity of the New Dock works; the other, the "Spit" light, just outside of Calshot Castle, marking the entrance to the Southampton Water. The buoys are in accordance with the uniform system of buoyage, and are shortly to be supplemented by four gas buoys—Pintsch's system. Three of these are to be put down by the Trinity House, in the Solent, to mark the approach to the port from the westward, and the other by the Harbour Board in Southampton Water. All four are to be lighted and maintained by the Harbour Board, the London and South-Western Railway Company making a considerable contribution towards the expense incurred. The Royal Pier, which has lately been reconstructed by the Harbour Board, is used for excursion and steamboat traffic, and the South-Western trains go alongside the steamers, which run in connection with them, for Cowes, Ryde, and the Isle of Wight traffic generally. A spacious pavilion has also just been completed on the pier. The Harbour Board are also engaged at the present time, with the South-Western Railway Company as their contractors, in the important work of bringing the five-fathom line right up from abreast of Netley to the entrance of the Empress Dock, so as to afford a minimum depth of 30ft. at low water of ordinary spring tides, and thus allow any vessel at present afloat to come up to our quays at any time of the tide.

The Harbour Board (or Commissioners) consists of the members of the Corporation of Southampton, and ten Specific Commissioners, who are practically life members of the Board. The Mayor, who is also Admiral of the Port, is elected chairman of the Board, with a virtually permanent deputy-chairman re-elected annually. The statutes which now govern the Board are those passed between the years 1863 and 1891. The debt of the Board is upwards of £200,000, and their revenue from all sources about £18,000 per annum. Although, as already stated, powers were obtained for the construction of docks as far back as the year 1803, nothing was done in this direction till 1836, when an Act was obtained by the Southampton Dock Company giving them similar powers. This was two years after the Act had been obtained for the construction of the London and Southampton Railway, and the two undertakings—so dependent on each other—were carried out almost simultaneously, the railway being opened throughout in 1840, and the sixteen acres of tidal or open dock completed and opened in 1843. The inner or Close Dock was not opened till 1851. This dock is the only one possessing a pair of gates. It is ten acres in extent, and has a depth of 25ft. to 28ft. of water, the depth in the open dock varying from 18ft. at low water to 31ft. at high water of ordinary spring tides. The Extension Quay on the river Itchen was completed in 1876, is 1720ft. in length, and has a depth of 20ft. at L.W.O.S.T. This quay is principally used by the Cape mail and other steamers of the Union Steamship Company.

Next in order of completion is the Empress Dock, opened by her Majesty in 1890. This fine dock is 18½ acres in extent, and has four quays of 850ft. each in length, with 26ft. depth of water alongside at L.W.O.S.T. This dock is used by the steamers of the American line, and by the larger steamers, such as the Nile and Danube of the Royal Mail Steam Packet Company, and the Scot of the Union Steamship Company. It is no uncommon thing for these steamers to dock and undock at dead low water, a feat which cannot be accomplished at any other port in the United Kingdom. A large warehouse is approaching completion on the north side of the inner or close dock. This building, 300ft. in length and 100ft. in breadth, and consisting of eight floors and a basement, is designed for the accommodation of grain, flour, and general merchandise, including bacon, cheese, and American provisions generally, also champagne, which is shipped in considerable quantities from France, *viâ* Havre, and is stored in the various vaults of the company. This warehouse, like the others adjacent, will be fitted up with elevators and conveying machinery of modern design, capable of dealing with 100 tons of grain per hour, either from ship, lighter, or railway truck.

In the close and open docks there are three sets of sheer legs, varying in power from 20 to 100 tons, and a large number of hydraulic cranes of various powers. The boilers and engines for this installation, as also the miles of pressure pipe used for the distribution of the hydraulic power over the dock estate, were supplied by Messrs. John Abbot and Co., of Gateshead-on-Tyne. The boilers —three in number—are of the Galloway type, 30ft. long by 7ft. 6in. in diameter, and are worked at a pressure of 120 lb. per square inch. The pair of tandem compound surface condensing engines are capable of pumping 300 gallons of water per minute at 750 lb. per square inch accumulator pressure. The plant is capable of working about thirty cranes of lifting power, varying from 20 cwt. to 100 cwt., as also the elevators, grain conveyors, coal hoist, and capstans. Some of the cranes were constructed by Messrs. John Abbot and Co., the makers of the engines, and the remainder of the cranes, together with the large shiphauling capstans, by Messrs. Sir William G. Armstrong, Mitchell and Co., of Newcastle-on-Tyne. There has also been put down by the railway company at the docks a very complete installation of electric lighting plant.

On the south side of the tidal basin are four dry docks of the following capacity, affording unusual facilities for the inspection and repair of ships:—

| | | | | |
|---|---|---|---|---|
| No. 1 ... | 400ft. long | 66ft. wide | Depth on sill, | 17ft. H.W. Neaps |
| No. 2 ... | 250 „ | 51 „ | „ „ | 11 „ „ |
| No. 3 ... | 500 „ | 80 „ | „ „ | 21 „ „ |
| No. 4 ... | 450 „ | 56 „ | „ „ | 21 „ „ |

The water is pumped from these docks by powerful steam engines, driving centrifugal pumps — Gwynne's "Invincible" type; and, owing to the convenience of the arrangements, coupled with the fact, almost peculiar to Southampton, that there is a double high tide—practically a state of high water lasting about four hours—it has been found possible to undock as many as three large vessels, and to dock an equal number on the same tide. This double high water at Southampton appears to be caused by the tidal wave being divided on its way up the English Channel by the western or Needles end of the Isle of Wight, one portion proceeding up the Solent and Southampton Water to Southampton, and the remainder continuing on its course on the southern side of the Island. By the time the first high water is over, and the tide shows signs of ebbing at Southampton, the flood tide has worked its way round by Spithead, and, meeting the ebb, practically dams, and holds it up so long as the tidal stream is working westward. As soon as the tide turns at Spithead, and the stream begins to work to the eastward, the real ebb commences from Southampton Water, and runs strongly out, having so much less time in which to do its work than is allowed for the flood tide. This increased rate of the ebb, as compared with the flood, has also no doubt a great deal to do with the scouring of the various channels in connection with the harbour and Southampton Water.

The author then proceeded to give a short account of the works now in progress for the provision of deep water quays on the rivers Itchen and Test, and of the new graving dock situated between the two. This graving dock will be, when completed, the largest single graving dock in the world. Its length on floor is 750ft., which could be extended to 1000ft. or more if ever required. The width at entrance is 87ft. 6in. at sill level, and 91ft. at cope. The depth on blocks will be 29ft. 6in. at high-water neaps. It will be provided with a ship caisson carrying road and railway from the Empress Dock to the Itchen New Quays. There will be a recess provided for the reception of the caisson during the operation of docking or undocking a vessel. There will also be hydraulic capstans and a large travelling crane, capable of lifting 30 tons from the centre of the dock. The caisson stop and sluice faces are of Cornish granite patent axed, the walls and invert of Portland cement concrete faced with brickwork, and the altars and steps of granite. The walls are founded 53ft. and the bottom of the invert 59ft. below cope level. The trenches for the walls necessitated very heavy timbering—in some cases as much as two cubic feet per cubic yard excavated. They were kept dry by two 24in. and two 18in. rocker pumps, throwing jointly between 3000 and 4000 gallons of water per minute. The capacity of the dock at high-water neaps will be about 14½ million gallons, which, with a ship in, can be emptied in from one and a-half to two hours by a pair of Gwynne's 48in. "Invincible" pumps, capable of delivering 112,000 gallons per minute. The discharge will be through two culverts 8ft. by 6ft. 9in., and all valves and sluices will be worked by hydraulic power. Provision is made for additional hydraulic pumps, accumulator, &c. Steam will be provided by four Galloway boilers 30ft., by 7ft. 6in. diameter, space being left for two extra boilers. The exhaust from the engines will be carried up the chimney shaft—which will be 120ft. high—to increase the draught. The chief feature in the construction of the pumping plant was the large excavation for pump foundations and well, a space nearly 90ft. square and 58ft. deep having been taken out and timbered in one piece. The greater portion of the graving dock site was reclaimed from the estuary by a chalk enclosing bank, the area within which was thoroughly drained, and the walls built in trenches. This enclosing bank was completed twelve months ago, since which time 136,000 cubic yards of excavation in trenches and otherwise has been done, and 55,000 cubic yards of Portland cement concrete put in. (*a*) The guide stage, reaching from the south dock head of the Empress Dock, about 300ft. long, is composed of piles and timber framing and deck, and is filled up to low-water level with concrete. (*b*) The east or Itchen Quay is also composed chiefly of a timber and concrete structure similar to the preceding, in all 1600ft. long. (*c*) The South Quay, 430ft. long. (*d*) The Southwest or Test Quay, 1500ft. long. In all, 3830 lineal feet of quay.

About 1150ft. of the Test Quay will be enclosed by a chalk bank, and the wall put in in the dry, as in the case of the graving dock. Another method of construction will be necessary for the outer and deeper portion. There will be 28ft. at L.W.O.S.T. alongside these quays, necessitating dredging upwards of one and a half to two million cubic yards of material. This depth can at any time be increased to 30ft., the foundations being put in deep enough to admit of dredging to that extent. The extension works are being carried out by Messrs. Lucas and Aird, Messrs. Galbraith and Church, of Westminster, being the engineers. The contractors are represented on the spot by Mr. William Coulson, C.E., and the engineers by Mr. Maurice F. G. Wilson, C.E.

The following items will be interesting, showing the number — approximately — of men, machines, and materials required in the execution of the works:—1100 men; 85 locomotives, cranes, &c.—(7 locomotives); 10,000 loads timber; 40,000 tons of cement; 2,000,000 bricks; 3 dredgers; 26 barges and hoppers; 5 tugs and launches. The paper concluded with long appendices sketching the career of the various large steam shipping companies using Southampton.

We have already very fully illustrated and described the Southampton Docks, but the map, which is a reduced copy of one given by Mr. Dixon, is needed in order to show the new graving dock and other works, which are pretty fully described by Mr. Dixon.

No discussion followed. Indeed, Mr. Dixon took care to explain that he had carefully avoided all controversial matter. For example, we may say that he scarcely alluded to cement concrete. Sir E. J. Reed proposed a vote to Mr. Dixon in a few well-chosen words, calling special attention to the important part which great railway companies have played in later years in developing dock accommodation. A vote of thanks was passed unanimously.

The next paper read was by M. Normand. Certain explanations were given by M. Normand, in order to save his hearers the trouble of asking questions. The trials named took place under the auspices of the French Naval Commission, and were not contractors' trials. The boats were small, 118ft. long by 13ft. beam. They were all tested with sufficient coal on board to carry them 1500 miles at ten knots. The contract speed was twenty-one knots. The actual speed during a four hours' trial was twenty-four knots. The boilers evaporated 37 lb. of water per hour per square foot of grate surface. The consumption of coal at full speed was 70 lb. per hour per square foot of grate; at ten knots it fell to 8 lb. M. Normand gave a table, from which we extract the following figures:—

| No. of boat. | Reduced speed—knots. | Consumption of coal in pounds per knot. | |
|---|---|---|---|
| | | Without heater. | With heater. |
| 149 | 10 | 15·20 | 12·03 |
| 152 | 10 | 17·0 | 12·4 |

The saving effected was at the rate of 20 per cent. The weight of the machinery with one boiler came out at about 48 lb. per horse-power. With two boilers for the same power it came out a little heavier, viz., about 53 lb., but in certain boats now being built by M. Normand, it was hoped that the weight would be yet further reduced. The following is an abstract of M. Normand's paper:—

### ON THE IMPORTANCE OF ECONOMY OF FUEL IN VERY FAST VESSELS, AND ON THE ADVANTAGES TO BE DERIVED FROM HEATING THE FEED WATER.

The author said that economy of fuel is universally admitted to be of great importance from a commercial point of view. It has, however, not always been acknowledged as a means for attaining extraordinary speeds. In the cases where very high speeds are to be attained some engineers dispense with steam jackets, feed heaters, &c. in order to save weight, overlooking this important fact that the necessary increase in the weight of boilers is greatly superior to the saving thus effected. Economy of fuel is not less important when looked at in regard to the bunker space occupied, and especially to the length occupied in the boat by the machinery and boilers, as well as by the necessary number of stokers to be carried. Between two sets of engines one requiring six boilers and the other only four, there can be no hesitation which to choose if the reduction may be obtained by making a few simple and practical additions to the machinery. Such differences in the boiler power required, as above mentioned, are not unusual. Taking, for instance, the consumption of my last torpedo boats, which ranged, according to official trials, from 1·1 lb. of coal per indicated horse-power per hour up to 15 knots and to less than 2 lb. at 25 knots, this consumption is certainly not more than two-thirds that of a number of similar craft. The total weight of engines and boilers of the boats above alluded to is about 48 lb. per maximum indicated horse-power; this weight has been still further reduced in the Chevalier, and notably in the the Forban, now under construction in my yard. From this it is evident that economy in coal really means economy in weight on account of the large reductions that are possible in the boiler power.

The author showed in 1885,* and this rule has been since verified in a number of cases, and is now generally assumed to be true, that, in cruisers, torpedo gunboats, torpedo-boats, &c., if the speed, steaming distance, weight of armament, and general conditions remained unchanged, a reduction in the weight of any part of the ship allows the whole displacement to be reduced by about 4½ times the weight saved. We see therefore that in light war-vessels, for instance, any given problem may be solved with widely different displacements according as the engines are, or are not economical; in fact, the necessary displacement may be as one to two, according to the weight and economy of the engines, and when extraordinary speeds are imposed exceedingly economical and light engines become a necessity. The remarkable economy of his own engines may be ascribed to several causes, but more particularly to the feed heater. This apparatus, whereby the temperature of the feed may be as much as 240 deg. Fah. at full speed, gives an economy in fuel consumed of at least 20 per cent., as has been officially proved by comparative experiments on four different boats. The principle of the feed heater, enunciated for the first time in 1856 by his brother Benjamin, is a direct application of the first law of thermodynamics. The heating steam is taken, in compound engines, at mid stroke from the low-pressure cylinder by a special valve, and in triple and quadruple engines direct from the low pressure casing, all the work previously given up in the engine by the heating steam being a direct gain. The advantages of the surface-feed heater over the injection feed heater seem to be as follows:—(1) The temperature of the steam is not limited to some degrees under 212 deg. Fah. (2) No particular head or height of the heater above the pumps is necessary. (3) No trouble is experienced with the feed pumps having to pump hot water, as the heating of the feed water takes place under pressure between the delivery of the pumps and the boiler.

Now, the economy of 20 per cent. above referred to, and which has often been challenged, requires some explanation. It may be ascribed to two causes:—(*a*) That which results from the number of thermal units saved by using, for heating the feed, steam which has already done work; this may amount to from 10 per cent. to 14 per cent., according to the pressure. (*b*) That which results from the better circulation of the water in the boiler, a greater proportion of that water being at a boiling temperature. The upward motion of the water in the heating tube by the bubbles of steam is purely mechanical—as in the "Pohle" air lift pump so much spoken of now—and the resulting increase in the transmission of heat is quite consistent with the well-known experiments described by Ser in his "Traité de Physique Industrielle," from which he draws the following conclusion (vol. i. p. 227)—"The transmission of heat for the same difference of temperature is more than tripled when the liquid is boiling, which is due to the greater speed in the circulation of the heated liquid." Greater speed in circulation means greater agitation, and the same cause may explain how, by placing baffles in the tubes of my feed heater the transmission of heat has been more than doubled. These baffles are removable, so as to allow of the cleaning of the tubes. Whatever may be the true explanation of the economy realised, its existence is beyond all question. On a trial of one of the first-class torpedo-boats the valve of the automatic trap attached to the heater had been left closed, and the heater was not in action: in spite of every possible exertion the revolutions could not be made to exceed 305 per minute. When the error was discovered the feed heater was put into action, and immediately the revolutions rose to 335; but, unfortunately, the trial had to be abandoned, as some minutes later some of the fire bars fell into the ashpit, on account of the heavy firing that had previously taken place when the heater was not at work.

There was practically no discussion. Mr. Thornycroft said that he congratulated M. Normand. These gentlemen had the advantage not possessed by English firms of being constantly employed on torpedo work, and were, therefore, able to make steady because continuous progress. The weight named—48 lb. per horse-power—was about that of the machinery of the Daring. A few words from Sir N. Barnaby, and a vote of thanks to M. Normand, ended the discussion. Possibly something more will be heard of the remarkable statement that an economy of 20 per cent. is realised by the use of live steam for heating the feed. Of course, nothing like this is possible in theory. The phenomenon is akin to the startling results attained by Mr. Kirkaldy, and confirmed not only by the reports of numerous superintending engineers, but by our own experiments on board the Thames steamer Oriole, and fully reported in our pages at the time. Let the explanation be what it may, there are, as M. Normand says, the facts. We may add that full particulars of all that M. Normand has done in the way of compression, the construction of tubulous boilers, &c., has already been fully described at various times in our pages.

As time permitted, a short paper by Mr. Thornycroft on "Circulation" was read. This paper we give in full on page 80. The discussion which followed amounted to very little. After a few remarks by M. Normand, Mr. Watt said that it was quite possible to have over-circulation, which resulted in leaving the tubes for a period dry. This would have little effect but that the tubes were galvanised. As soon as they became over-heated the zinc was attacked by the dry steam, hydrogen was liberated, and rapid corrosion set in. Mr. Watt was followed by another speaker, who explained how it is that Mr. Maxim has attained such wonderful results with his flying machine boiler, which weighs 4 lb. only per indicated horse-power. The boiler is in type Thornycroft's, but the copper tubes are only $\frac{3}{8}$in. internal diameter. It was found at first that the boiler could not be forced, as the tubes boiled dry, because the water did not descend the down pipe fast enough to make up the quantity discharged upwards by the steaming tubes. He overcame the difficulty in the way shown in the annexed sketch. A is the steam drum, B is a pipe reaching some distance down the down feeder pipe F. The feed water comes in through E. There is a valve at D, kept up to its seat by a spring at C, where there is a stuffing-box for the valve rod to pass through. Matters are so arranged that the pressure on the boiler being 300 lb., the pressure of the feed necessary to pass D is 350 lb. The result is that the feed comes in in a thin stream at a high velocity,

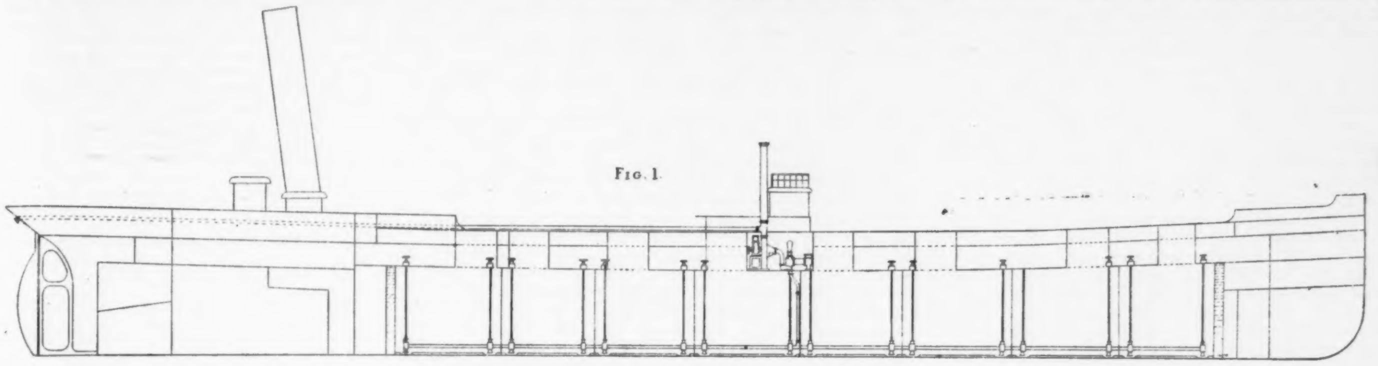

FIG. 1.

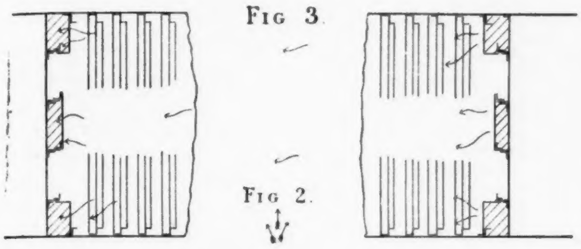

FIG 3.

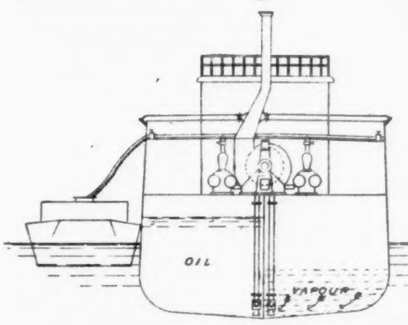

FIG 2.

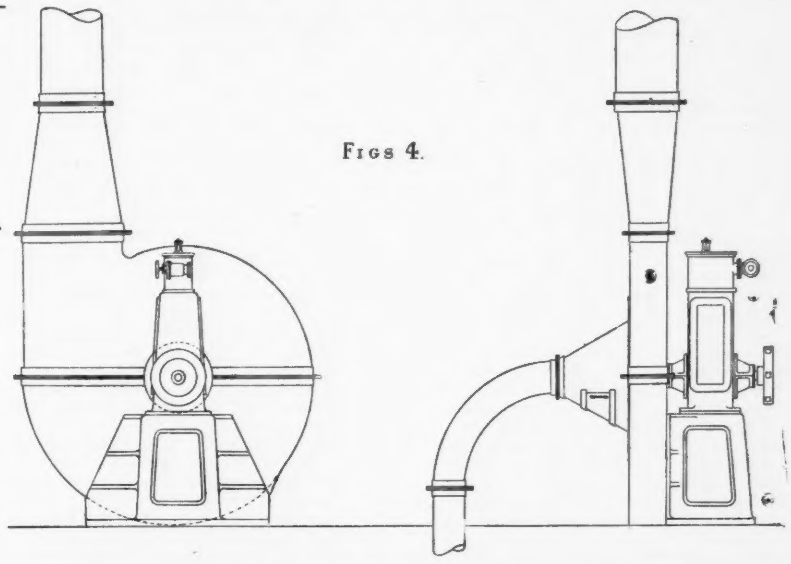


FIGS 4.

and induces so powerful a down draught in B that it is impossible to keep any water standing in A. This is a complete success, and enables the boiler to be forced to an unlimited extent.

Mr. Thornycroft said that he had used $\frac{3}{8}$in. tubes with success, but he had not gone further. The circulation in a small tube boiler could not be too violent. In a large tube boiler the water did not get changed, because there was room for the bubbles of steam to pass up. They did not fill the tube, and the water slipped past them. Such boilers would fur up. The circulation in them was quite insignificant as compared with that in a small tube. He had found tubes in his boilers in good condition after five years' work. Originally the tubes were 15 B.W.G., now they were about 16 B.W.G.

The proceedings now terminated, and the members proceeded to the pavilion on the new Royal Pier, by the invitation of Mr. Morgan and the members of the Chamber of Commerce. Here an admirable luncheon was served, and the members and visitors subsequently went on board the Solent Queen and proceeded round the docks, landing those who wished at the new dock works described in Mr. Dixon's paper. Here much of interest was seen. Unfortunately a dense fall of fine rain interfered much with everyone's comfort.

In the evening about 300 of the members and visitors dined at the Royal Victoria Rooms. Many speeches of the usual type were made, and the proceedings did not terminate till a late hour.

On Wednesday morning the proceedings began at 10.30 with the reading of a paper by Professor Biles "On the Designs of Mail Steamers, with special reference to their use for War Purposes." The paper does not admit of being abstracted, and the issues it raises are very important. It is a long paper, too. We shall publish it in our next impression.

The discussion was opened by Lord Brassey, Mr. Morgan taking the chair. Lord Brassey began by saying that he did not intend to touch on technical points, but that while others were reading and digesting the paper he could say a little as to its general scope. The commerce of Great Britain was enormous, and to protect it an enormous number of cruisers was needed. Was it desirable to build a number of vessels to be used as war ships in times of war, as mail ships in time of peace? He answered, Yes. The Admiralty had already accepted the principle by subsidising mail steamers under certain conditions. There were obviously financial difficulties in carrying out Professor Biles' plans. These should be met by the State. But very great care should be taken that ships built to meet Admiralty views, and subsidised by the Government, must not be sold to foreign Governments or sailed under the flag of another nation, as had occurred in the case of two large steamers. He hoped that Professor Biles' important paper would receive proper attention from the authorities. He held that the Government treated the mail service on principles of utterly undue economy. The whole sum spent on the postal service by Great Britain, France, Germany, and Italy was £3,331,000 per annum, and of this Great Britain spent only 20 per cent. As compared with the annual revenue, the expenditure of Great Britain was as one to 1161, and that of the other nations named as one to 336; and France spent besides very large sums on subsidies.

After a few words from Mr. Morgan, Sir Edward Harland continued the discussion. It may be well to explain here that one of the essential features of Mr. Biles' scheme is that the sides of the ship should be recessed along the water line, 5ft. above it and 5ft. below it, and that within these recesses when fitted for war, armour-plates and backing kept in readiness should be put and secured; protection is also to be afforded by the coal bunkers.

Sir Edward Harland began by saying that he had not had time to read and consider the paper, but he could congratulate the author on the way in which he had handled a very complex question. He was glad to find that the views of the Bulkhead Committee were adopted. The subdivision of large ships was very much more easily carried out, without interference with cargo, than that of small ships, and as Mr. Biles contemplated a ship 500ft. long, the bulkhead part of his scheme presented few difficulties as to the boilers. Firing fore and aft presented so many advantages, that he wondered the Admiralty had not adopted it long since. No trimming worth mentioning was required; none of the expense incurred in dragging sacks of coal to the stokehold plates. The 'thwartship system of firing would not be tolerated for a moment, because of the expense, in the Mercantile Marine. He could not at all endorse Professor Biles' views in favour of short stroke engines; it was too terrible a sacrifice to contemplate with equanimity. The Great Eastern had screw engines whose stroke was so short that great loss of power was incurred by friction. As to the recesses for the armour plates, he held that they would sacrifice the longitudinal strength of the hull, which lay in the skin, and any loss there could scarcely ever be made up. Again, he held that the interest on the cost of the plates would be an enormous item. As to the value as protection of fore and aft bunkers, he doubted that it would be worth having. If a shot went through, the coal would prevent any steps being taken to plug the hole. The Admiralty had, he believed, carried out some experiments years ago to test the value of coal protection, but the results had not, to his knowledge, been made public. The Admiralty were much to blame for the delay in publishing the results of experiments. The extra weight to be carried—600 tons—would be a severe tax in the merchant service, and he did not think that the double bulkhead, with a space of 3ft. between the two, could possibly find favour with shipowners. The paper was no doubt valuable, in that it would raise the question whether it was better to build mail steamers which could be converted into war ships at a large expense, or to spend the same money on real men-of-war. We did not go to war once in six years, or in sixty years, and he really thought that as regarded Mr. Biles' schemes the game was not worth the candle.

Mr. Martell followed with an amusing speech, which, however, left the subject much as he found it. He held that there would be no difficulty in making a ship strong enough in spite of the recesses. There was a great deal of nonsense talked about protecting and arming mail boats. Mr. Biles had taken this and crystallised it, so that it could be criticised. The British Government was not only mean, but dishonest. After getting ships on the Admiralty list, holding out as a reward, that if the Government wanted ships, those on the list would be ememployed, they, the moment some vessels were wanted for trooping, took ships which not only were not classed on the Admiralty list, but were not classed at all anywhere. As for coal armour, experiments had proved that it was useful. He saw nothing impracticable in Mr. Biles' scheme but the cost.

Admiral Boys agreed with Sir E. Harland, that they had not had time to master the paper. Everyone, however, knew, that a battleship was a compromise, and Mr. Biles would produce ships which were more a compromise than ever. He held that the proposed ships would not be in any way first-class cruisers. Far from it. The proper functions of a mail boat in war time would be to carry a light armament for her own defence, and trust to her heels for the rest. No attempt should be made to render her an offensive weapon. Coal targets had been tried by the Admiralty, and their value had been abundantly proved.

Mr. Sydney Barnaby said that the paper did not embody the views of an idle dreamer, but of a man who knew very well what he was about. Sir N. Barnaby had advocated a somewhat similar scheme before the Institution of Civil Engineers, and Sir F. Bramwell denounced it, saying that such a scheme for a compromise between a man-of-war and a merchant ship was to him like a red rag to a bull. It seemed to him that Mr. Biles had not included all the objections to the scheme in his paper. Thus the beam of the ships and her resistance would be increased. He thought that instead of using side armour weighing some 1300 tons, it would be better to use two decks, one a little above, the other a little below, the waterline, and pack the space between with a water-excluding material weighing about 330 tons. He did not think that in war there would be time to put on armour, but the space between the decks might be packed in a couple of days. Before sitting down, he would like to ask for information about the Russian Vounteer Fleet.

Mr. Denny said that his firm had built two Russian ships, but there was nothing exceptional about them except that the bulkheads were rather more numerous than usual. They were only to carry a few light guns. There was nothing impracticable in Mr. Biles' scheme; it was all a question of expense, and he thought that such ships would be less likely to come to grief than men-of-war, because the machinery would be constantly at work, and the crew would know all about it. He would rather be in such a ship than in one of the terribly complicated cruisers, with an engine-room crew on board who had had no acquaintance with the ship or her machinery. He feared Mr. Biles, in calculating weights, had forgotten water ballast. There was no difficulty in making the ship strong enough. He did not like wells in double bottoms, with non-return valves which never acted.

Mr. Swan corroborated Sir Edward Harland about the recesses. Instead, he would use a permanent shelf, on which the armour could be carried when necessary. This would be cheaper, and quicker to use in time of war. Flat armour-plates might be kept in stock, which would fit any ship.

Professor Biles, replying, said that he was quite aware that he was going to arouse opposition. He had summarised what had no doubt been on men's minds before. He was certain that if we went to war we should want many cruisers, and that we could not produce them fast enough. Something must be sent to sea. Was it not best to recognise and act on this early enough, and design our great mail steamers accordingly? If Sir Edward Harland would read his paper carefully, he thought Sir Edward's views would be modified. After all, there was not very much change entailed. As to the 600 tons extra, he did not think that a matter of much consequence in a large ship, especially as much of the goods carried were measurement, not dead weight. As to short stroke, the term was fairly comprehensive, and the tendency was all to reduce stroke. Sir Edward could no doubt remember a ship indicating 10,000-horse power, built about fifteen years ago, in which the stroke was 6¼ft., while now ships of 20,000-horse power had a stroke of only 5ft. Short strokes answered very well in warships. Coal did give wonderful protection. Sir Edward had said he would like empty bunkers, that he might be able to plug the holes, but a shell would blow a hole 6ft. square in a ship's side. How would he plug that? Mr. Barnaby's suggestion was very useful, only where was the material needed to be got? Mr. Swan's notions about a shelf Mr. Biles had considered very carefully, but he liked the recesses best, because less skill would be needed at a time when skilled labour would be scarce, in putting on the armour plates.

Mr. Morgan concluded the discussion by saying that coal had proved of wonderful value in quenching the effect of small shells from quick-fire guns, which would otherwise wreck a ship's side in a few minutes, and destroy her inboard.

A vote of thanks to Mr. Biles was passed unanimously.

Mr. Denny then read a paper on "A Rapid Method of Calculating Wetted Surfaces." It is a mathematical paper, and will not bear compression. No discussion followed.

The members then adjourned to the mail steamer Scot, a magnificent ship which has already been very fully described in our paper. On board her a superb luncheon was served, the hosts being the chairman and directors of the Union Steamship Company, and at 4 p.m. the members and guests proceeded to Bassett Hall, where a garden party was given by the Mayor. This terminated the day's proceedings.

Yesterday two papers were read, namely, one by Mr. F. Gross, descriptive of the results obtained from the use of cylindrical boilers fitted with Serve tube, and what is described as the "Ellis and Eaves suction draught" for steamships. To this paper we must return in another issue. The second paper was by Mr. Stephen H. Terry and Mr. Fortescue Flannery, of which the following is an abstract:—

### "The Ventilation of Steamships and Bulk Oil Steamers."

This paper is a description of methods of ventilation invented by the authors. Having referred to the principles of colliery ventilation, the authors of this paper approached the subject of ship ventilation. They were aware that various arrangements and appliances have been proposed and are more or less largely adopted; under these air is blown into cargo and passenger space, by the use of various forms of windsails and cowls, and by specially patented forms of these. More elaborate systems in which air—under slight pressure due to the use of jets of steam or compressed air jets—has been caused to pass into various parts of a vessel have also been used to some extent, and in some cases have given fairly satisfactory results. Exhaust ventilation with these appliances has also been to some extent adopted. A special class of vessel, carrying cargoes of a nature where risks are, or were, so considerable that the premium of insurance used to be, and still is in some cases, 7 per cent., came under the notice and attention of the authors, namely petroleum tank steamers. In these vessels, after the cargo has been removed by pumping, vapour of considerable density is formed by the evaporation of such of the liquid as remains adhering to the surfaces of the skin and frames, &c., of the vessel, such vapour having a specific gravity up to three and a-half times that of air, or twice that of carbonic acid gas. In the endeavours made by others to ventilate vessels carrying this sort of cargo, the desired end was sought in blowing fresh air, by means of fans or jets, into the holds or tanks, under the impression that the foul air would thus be displaced and expelled. With colliery practice in their minds, the authors conceived that a more efficient ventilation per cubic foot of air or vapour moved would be attained if suction instead of pressure were adopted when dealing with vapours of high specific gravity. Their reason for holding this view being that the vapour to be removed is, owing to its weight, found lying in the lowest parts of the vessel in a dense condition, and that when suction is employed the fan draws it down as water in a well is lowered by pumping, the fan being engaged for some time after starting in passing almost pure vapour, only drawing fresh or comparatively fresh air after complete removal of the foul vapour has taken place.

To meet the conditions laid down by the authors, namely, the suction of a very large volume of air through a relatively small pipe,* Mr. Chandler designed a special type of fan some 6ft. in diameter by 10in. wide on the face, with a single inlet and reducing nozzle; the fan and engine—the latter single-acting—capable of running continuously at 500 revolutions a minute, giving a water gauge of 12in., and the theoretical air velocity of 13·738ft. per minute; the water gauge was guaranteed. At the trial, however, with steam at 120 lb. pressure, exhausting to the atmosphere, a water gauge of 16in., with a delivery of some 8000 cubit feet per minute was easily attained. The capacity of a 5000-ton oil boat, at 40 cubic feet per ton, is 200,000 cubic feet.† By this system, and with an apparatus of the dimensions named, the whole of the air in a vessel of this size would be removed and changed once in twenty-five minutes, or nearly two and a half times per hour.

The system designed and patented by the authors consists of ventilation by suction through the oil pipes provided in tankers for discharging cargo. Such pipes are found sufficiently large for the purpose in modern bulk oil steamers, where they are generally 10in. in diameter. In cases where large bilge pipes or ballast pump suction pipes are fitted, good results as to ventilation of ballast tanks are attained by putting them in the fan suction circuit. An important feature in the achievement of success by this system is the high efficiency of Mr. Chandler's fan and engine, which gives a relatively high water gauge (16in.) at a moderate speed of engine. In this way a machine has been combined capable of exhausting at a water gauge such as might have been looked for in a pump, whilst the volume dealt with has been that due to a fan. It is the old story of centrifugal pumps *versus* reciprocating pumps, the former have almost entirely ousted the latter for circulating purposes.

The diagram—p. 75—illustrates the application of this system to a vessel with a capacity of 5000 tons of oil. In the diagram it will be seen that there are the usual coffer or caisson dams at the forward and after ends of the oil spaces. There is a longitudinal bulkhead running from the machinery space to the forward bulkhead. The oil suction horizontal mains are laid in duplicate fore and aft, on each side of the central bulkhead. Suction pipes with bell mouths draw from the fore and aft end of each tank. The horizontal mains are connected with the oil pumps—which are in duplicate—by two vertical suction pipes, of which one only is shown in the drawing; these, again, are connected by cross-over pipes, so that either pump can draw from any tank, forward or aft, port or starboard. Aft of the pumps is shown the engine and fan, with its reducing nozzle to bring the suction side casing down to the required 10in. diameter—the size of all the pipes. Oil-tight, double-seated valves are provided to connect and disconnect the pumps and fan as required. In this case provision has only been made for blowing the air and vapour from the fan straight upwards or right aft, where, issuing at a high velocity, it rapidly mixes with the surrounding atmosphere. This arrangement has already been fitted in about a score of vessels. In the case of some other vessels provision has been made—by means of a four-way flap-valve air trunk—for diverting the issuing vapour to whichever side may be desired, either to port or starboard or straight up. This arrangment is shown in the transverse section of the vessel—Fig. 2. The port pump is at work discharging cargo into the tank lighter alongside, whilst the fan is removing vapours from the recently-emptied tank on the starboard side. In the longitudinal section—Fig. 1—although only one vertical suction pipe is shown on the starboard or nearest side of the longitudinal bulkhead, there is a second pipe on the port side; and it would perhaps be advisable to fit four of these vertical pipes instead of two only, as it gives a greater number of combinations for pumps and fan at one and the same time. As shown in the diagrams, the additions needed for the ventilating system have been limited to the engine and fan, as no alterations or additions to the pipe system were made, except the fan coupling pipe and valve. The cost of the complete system has been less than ·01 of the cost of the ship.

There was only a brief discussion on these papers, and at its conclusion the members adjourned for a visit to the steamship Paris. This concluded the day's programme.

## PLANING MACHINE.

We illustrate on page 82 a planing machine by Messrs. Joshua Buckton and Co., of Leeds, not so remarkable for its large size as some former machines of theirs, noticed in our pages, but remarkable—(1) For its special driving gear, which will run the table at 10ft. per minute, 20ft. per minute, or 40ft. per minute; (2) for its patent double-cutting tool-holders; (3) for the transverse planing action to one of the boxes on the cross slide. The large use of steel castings for machine tools and other engineering work at the present day makes it desirable to have the command of a slow and powerful motion to the table of a planing machine; but as the same machine may be used for planing ordinary cast iron, time would be lost if a rate of travel suitable for steel were used for cast iron.

In the machine illustrated gearing has been introduced which is well shown in the engraving, and in which a change of speed from 10ft. to 20ft. per minute is effected by merely throwing a lever, which draws one pinion out of gear and puts another into gear. If the double cutting tool boxes are in use, the same rate of speed is maintained on both strokes of the table, and plane surfaces are therefore finished without any time lost by an idle return stroke, and they are finished as truly by the first cut over, divided as it is between two cutting edges, as it could be by a second cut over if effected by a single cutting edge. Where, therefore, the double cutting principle can be applied, surfaces can be finished in less than half the time that would be occupied in finishing them in the ordinary way, with a single cutting tool and a quick return motion; but one hindrance to its adoption has hitherto been that there are certain pieces of work which do not permit of sufficient over-run to give room for two tools to work. To meet such cases, without losing time by a slow return of the table, a pair of wheels is provided, which when in gear, as shown in the illustration, bring back the table at the rate of 40ft. per minute, whether the 20ft. or the 10ft. cutting speed is in use. For the transverse cutting action on the cross slide, the same double tool box is used as for the longitudinal action. It is simply turned on its side, and so bolted to the tool slide.

The illustration shows the nearer tool-box fixed for longitudinal planing and the further one for transverse cutting. When the transverse cutting is in use, the feed motions either self-act the tool-box vertically downwards or will traverse the table horizontally with a feed motion which takes effect at each end of the transverse stroke, so as to feed each tool with a fresh cut. The machine illustrated will plane 20ft. long, 8ft. wide, 8ft. high; all its four tool-boxes are fitted with feed motions for horizontal, vertical, and angular cuts. This machine has been purchased by the Vulcan Works, of Vienna, from Messrs. Buckton, who have now in hand another one exactly like it, as well as smaller machines on the same principles. The approximate weight of the machine is 40 tons.

## BOILER EXPLOSIONS.

We have received a copy of the report of the Chief-engineer to the National Boiler and General Insurance Company, which is well worth perusal. After stating that the company has added the insurance of steam engines to its other business, Mr. Hiller says that "the total number of thorough examinations of insured boilers made during the year shows that 89·5 per cent. of the boilers were so examined during the twelve months. This is equivalent to an interval of fifty-eight weeks between the consecutive examinations of each boiler. This result is satisfactory, taking account of the fact that the boilers insured by the company are situated in all parts of the United Kingdom, from the most sparsely populated and remote rural districts to the great industrial centres, where the boilers are situated near together. There is little doubt that if the steam boilers could be prepared for examination at periods equally distributed in the course of the year, we should be able to examine every boiler thoroughly once in twelve months; but in many cases where firms have not more than one boiler, and also in several of the industrial centres, it is the practice to prepare the boilers for inspection at general holidays. At these times the requests for examinations are far in excess of what it is possible to undertake, even though we concentrate our staff in the district, to meet as far as practicable the demands upon us. In some districts it is the practice, where firms have a number of boilers, to prepare the boilers for examination in rotation during ordinary working periods of the year, and this course is the most satisfactory one. It allows time for the boilers to be properly cleaned, and for the fittings to be carefully overhauled and examined, and there is not that pressure of work which always interferes with examinations at general holiday times. It is greatly to be desired that the practice of having one spare boiler should be more generally adopted, and we believe that those firms who make this provision in their plant will find it to their advantage in every respect."

During 1893, 27 explosions of steam boilers in the United Kingdom were reported, which caused the deaths of 9 persons and injury to 22 others. The ordinary vertical boiler as usual heads the lists. Some of the causes which have contributed to this undesirable predominance are pointed out in the particulars given of some of the explosions, and also in the cases of external corrosion. The exploded boilers were of the following descriptions:—

| Description. | Internally fired. | Externally fired. | No of explosions |
|---|---|---|---|
| Vertical, with internal fire-box | 11 | — | 11 |
| Lancashire | 2 | — | 2 |
| Cornish | 2 | — | 2 |
| Locomotive | 2 | — | 2 |
| Portable (locomotive type) | 1 | — | 1 |
| Cylindrical, dish-ended | — | 2 | 2 |
| Cylindrical, egg-ended | — | 2 | 2 |
| Cylindrical, one-flued | — | 1 | 1 |
| Water-tube | — | 1 | 1 |
| Combined flue and tubular boiler | 1 | — | 1 |
| Irregular shaped cross section, two internal tubes | 1 | — | 1 |
| Cylindrical return flue | 1 | — | 1 |
| Totals | 21 | 6 | 27 |

*Causes from which the Explosions Arose.*

| | Persons killed. | Persons injured. | No. of explosions |
|---|---|---|---|
| Defective condition— | | | |
| External corrosion | — | 4 | 8 |
| General deterioration | — | 1 | 1 |
| Internal corrosion | — | 1 | 3 |
| Internal grooving | 3 | 3 | 4 |
| Mistake, negligence, or mismanagement— | | | |
| Over pressure | 1 | 6 | 2 |
| Deficiency of water | 4 | 3 | 5 |
| Overheating through deposit | 1 | — | 1 |
| Defects due to external firing— | | | |
| Fractures at riveted seams | — | 1 | 1 |
| Causes not ascertained— | | | |
| Information incomplete, evidence not conclusive | — | 3 | 2 |
| Totals | 9 | 22 | 27 |
| Total explosions, &c., from July 1st, 1864, to December 31st, 1893 | 1285 | 2265 | 1278 |

Brief particulars of some of the explosions included in the above table are given in the report. In one case a vertical boiler used in a coal pit exploded, owing to the safety valve becoming jammed by reason of the gradual rising of the ground at the part of the mine where the boiler was placed, until the safety-valve lever came into contact with the brickwork of the arch over the boiler. A somewhat similar accident nearly occurred in the case of a boiler under a building in a large city. There the floor above the boiler sank until the safety valve was in danger of being jammed. In this case the defect was fortunately detected in time, and it was found necessary entirely to reconstruct the floor.

The report contains a section on the construction of new boilers, with details of the procedure followed, where the advice and assistance of the company is sought in the construction and laying down of new boilers.

The North of England Institute of Mining and Mechanical Engineers.—The annual general meeting of the members will be held in the Wood Memorial Hall, Newcastle-upon-Tyne, at two o'clock on Saturday, August 4th.

The Late Mr. Alfred Williams.—The death is announced of Mr. Alfred Williams, C.E., the head of the firm of Alfred Williams and Co., of Bankside, Southwark, who has been for many years closely identified with gas engineering. His death took place on the morning of July 20th, at the age of 68, he having been in failing health for some time past. Mr. Williams was one of the founders of the Society of Engineers, and since its inauguration in 1854 has held the position of honorary secretary and treasurer, in which capacity he has rendered the society marked service.

Examinations for Naval Engineer Students.—The local examinations for engineer students will be held at Manchester and Birmingham, as well as other centres, in April next, but the exact date will not be fixed until January, and may then be obtained from the Civil Service Commissioners who conduct the examination. Candidates must not be less than fourteen nor more than seventeen on the 1st of May next. Successful candidates will be entered as engineer students in the Navy on the 1st of July, and will pass through a course of five years at the training school for engineer students at Keyham. The cost to parents is £40 for each year of the course.

---

* It being found desirable to provide means of changing the whole cubic contents of a ship every half hour, the pipes in the case of a vessel of 5000 tons oil capacity being 10in. in diameter, and consequently having a sectional area of 78in., or more than half a square foot.

† If the oil be of the density of ·9, or 9 lb. per gallon, refined oil, there will be 40 cubic feet, or 250 gallons to the ton. If the oil be unrefined, and weigh only 8 lb. per gallon, there will be 45 cubic feet, or 280 gallons to the ton.

## RAILWAY MATTERS.

THE Indian Government has sanctioned the doubling of the line between Karachi and Pipri Stations, twenty-six miles.

WE understand that it is expected that the West Highland Railway will be opened for passenger traffic in a day or two, as the signals and telegraphs will then be completed.

THE construction of the electric tramway at Champel-Petit-Saconnex, Geneva, which is being carried out for the Compagnie des Tramways Suisses, is being rapidly pushed forward.

THE Compagnie Générale des Omnibus is laying down in Paris the Mekarski compressed air system. We learn that three of these cars have been tried in Westfield, Mass., for about a month, and are giving excellent results.

NOTWITHSTANDING the heavy floods in India the work on the Jhelum Railway Bridge is being vigorously pushed on. The first girder has been placed on the first and second piers and all the necessary machinery erected to complete the fixing of the other girders.

THE Indian Government have repeated their orders to the Bombay-Baroda and Central India Railway Company for the renewal of the Warren girder bridges on their line. The representations of the company and their proposals for strengthening these structures have had no effect.

CONSIDERABLE railway progress is being made in Caucasia, chiefly in the direction of building lines to connect the agricultural and mining districts of that region with the sea coast or with the Russian trunk lines. The Austrian Consul at Batoum has reported the opening of about 200 miles of railroad in Caucasia last year. The most important of these extensions is a line—about 165 miles long—from Beslany to Petrovsk.

THE Mari-Attock Railway, one of the most difficult lines in India, is rapidly progressing. All the alignments have been found, and the bridges and viaducts have in most instances been completed. This railway is remarkable for the heavy nature of the works, and despite the difficulty of obtaining labour and the obstacles encountered, it is anticipated that the whole line of 96 miles will be completed by the end of 1895.

IT is stated that the Metropolitan Elevated Railroad Company of Chicago has placed contracts for equipping its line, five miles in length, with electric motive power. At the start fifty-five motor cars will be put in service, each equipped with two 100-horse power motors. For the power house, engine and dynamos aggregating 6000-horse power are planned. It is hoped to have the line in operation some time this autumn.

THE City line—Vienna Town Railway—which was originally given to the "Steam Tramway Company"—Kraus—is now to be constructed by the State, the Lower Austrian provincial authorities, and the Vienna Municipality unitedly. The physical position of the city is such as to have made the negotiations unusually prolonged and tedious. Vienna being situated in a valley encircled on three sides by undulating hills, greater difficulties are presented than were at first expected.

FLOODS have caused considerable damage to railway property in India, that to the Great Indian Peninsula Railway being the most extensive. A large iron bridge near Asirgarh has been carried away and the line breached in several places between there and Kalyan. It will consequently be some days before trains can run regularly. Further reports show that this is the most serious disaster that has happened since the line was opened. Several landslips have occurred on the Ghauts, the mouths of some tunnels have been blocked, and embankments have been swept away. One train was detained sixty hours between a broken embankment and a landslip, but it is believed that no lives have been lost, although some trains narrowly escaped destruction. Other railways have also suffered more or less injury. The traffic on the Bombay and Baroda Railway will be interrupted for some time. The North-Western Railway has been breached at Ruk, and the mouth of the Khojak Tunnel is blocked by landslips.

THE following are some important extracts from the general statement of the Director-General of Railways Administration Report on Railways in India for 1893-4:—The classification of railways in the report remains practically unchanged. During the year sanction was given to the construction of additional mileage to the extent of 154½ miles. Among the principal events were the bringing in of the automatic vacuum brakes on mail trains on the East Indian Railway and the accelerated mail service which has been generally introduced. There are sixty lines now under survey or projected, and these will be taken into consideration by the Government of India at an early date. The contribution this year for sinking funds will amount to about 38 lakhs, so that the net loss to the State will probably be about 121¾ lakhs of rupees. During 1893 the average gross earnings per total train mile were Rs. 4·20 on the standard gauge, and Rs. 3·12 on the metre gauge. The net earnings realised in 1893 were Rs. 12,73,65,012, against Rs. 12,32,57,767 in 1892. The increase this year in the number of passengers killed is due to the accident of November 9th, on the Nilghi branch, Madras Railway

IN an article on "Light Railways and Australian Progress," by R. Price-William, M.I.C.E., published in the *Engineering Review*, we read that the mileage of railways in operation in New South Wales, which in 1875 was only about 400 miles, increased in the following five years to nearly double that number; and that the annual gross receipts—about £600,000, or roundly £1500 per mile—also doubled in the same period, leaving the receipts per mile practically the same. Between 1880 and 1885 the mileage of railways opened again nearly doubled, 1700 miles, the gross traffic receipts increasing during that time to nearly £2,200,000, or very much in the same proportion. From 1885 to 1890, however, the mileage of railways opened and the traffic receipts increased much less rapidly. Although there was no addition made to the mileage from the beginning of 1890 to the middle of 1892, the amount of the traffic receipts has, as might be expected, continued to increase, but at a less rapid rate, the increase being due in a great measure to the natural growth of the traffic consequent upon the mileage of new railways opened in the previous years; and partly to the able management which, during the last few years of almost unexampled commercial depression, has characterised the railway administration in that colony.

THE damage to the South-Western line near Portsmouth has been repaired, and the ordinary traffic resumed. It will be remembered that on Monday evening last the 6.35 train from Havant left the rails, killing the guard and injuring three of the passengers. The permanent way was torn up for some distance, and the telegraph poles were broken. Had it not been for the presence of mind displayed by the engine-driver Hillier in promptly drawing the fire, and thus preventing an explosion, the water being low in the boiler, grave consequences might have ensued. Further report says that at the inquiry, the railway officials express the opinion that soon after passing the switch, where it was turned from the main line on to the branch line, the engine commenced to force the metals out of the straight. On arriving at the V point it left the rails. The reason of the engine leaving the metals was discussed at length, one juryman maintaining that the cause of the accident lay with the check-rail, a piece of metal by the side of the point and intended to force the engine's wheels to take the point. It has been found that the large chair holding the V point was broken, and that it had a flaw in it which, however, was not perceptible until after the fracture. The inquest has been adjourned until to-morrow week. Major Marindin, of the Board of Trade, opened an official inquiry on Wednesday.

## NOTES AND MEMORANDA.

IN a paper in the *Comptes Rendus* "On the Influence of Fluorine Compounds on Beer Ferments," by M. J. Effront, it is shown that ferments which have gradually become inured to the action of fluorine compounds give more alcohol and less glycerine and succinic acid than ordinary yeast from a given quantity of glucose.

IN their report on the composition and quality of the water supplied to London, for the month ending June 30th, 1894, Professor Crookes, F.R.S., and Dr. Odling, F.R.S., state that:—"The quality of the Thames-derived waters has remained excellent during the month of June. The analytical results are practically identical with those of the previous month, and also with those for June, 1893, the differences being in most instances confined to the third place of decimals; each unit in that position representing one part of extraneous matter in 70,000,000 parts of pure water; a fraction which, translated into units of length, is equivalent to about six yards in the distance between the earth and the moon—a wholly negligible quantity."

A METHOD for instantaneously removing iron parts shrunk on hot, like a crank on a shaft, has been communicated by M. N. J. Raffard to the *Bulletin Technologique* of the French Société des Anciens Elèves des Ecoles Nationales d'Arts et Métiers. An endeavour had been to take off the outer hoop of a Laval turbine by heating it with a gas blowpipe; but the heat was communicated too quickly throughout the whole mass to give a sufficient difference of expansion in the hoop alone, so as to loosen it, and there appeared no alternative but to cut it. In such a case, M. Raffard recommends that molten lead be run round the part to be detached, a method which he applied with success in 1860, at the Soho Foundry, Melbourne, in removing a crank that had been shrunk on a shaft of 8in. diameter.

THE following are given in the *Journal* of the Society of Chemical Industry as suitable cements for making joints in leather driving belts:—(1) Equal parts of good hide glue and American isinglass, softened in water for ten hours, and then boiled with pure tannin until the whole mass is sticky. The surfaces of the joint should be roughened and the cement applied hot. (2) 1 kilo. of finely-shredded gutta-percha digested over a water bath with 10 kilos. of benzol until quite dissolved, when 2 kilos. of linseed oil varnish are stirred in. (3) 1½ kilos. of finely-shredded india-rubber is completely dissolved in 10 kilos. of carbon bisulphide by heating. Whilst hot 1 kilo. of shellac and 1 kilo. of turpentine is added, and the solution heated until the two latter ingredients are also dissolved. (4) 1 kilo. of best glue is dissolved at a moderate heat in 1½ kilos. of water, and thickened to the consistency of syrup. 100 grms. of thick turpentine and 5 grms. of carbolic acid are carefully stirred in whilst hot. The mixture is poured into flat tin pans and allowed to cool, then cut into pieces and dried in the air. The cement is made liquid with a little vinegar and applied to the joint with a brush. The two ends of the joint are then placed together and pressed between two iron plates heated to about 30 deg. C.

A CORRESPONDENT writing to *Indian Engineering*, and referring to a selected paper of the Institution of Civil Engineers on the subject of "Hard Wood Pavements in Australia," by Mr. W. A. Smith, says:—"It has always struck me as very strange that soft wood should ever be used in a large city for carriageways. For ordinary roads the hardest and most refractory rocks are employed, *i.e.*, granite and trap—not sandstone nor soft limestones; why not the hardest woods for pavements? Probably the cheapness of Norwegian pine has led to this extraordinary practice; but even so the cost per square yard of soft wood pavements, as laid in London, is 5s. 6d., exclusive of concrete foundations, and the annual cost of maintenance is 5d. per square yard; and as this pavement only lasts seven years, the cost for twenty-one years of laying, relaying, and maintenance comes to 25s. 3d., not 17s. 9d., as stated in Mr. Smith's paper. This compares most unfavourably with the cost in Sydney, viz., 9s. 9d. for a close-jointed pavement, and 10s. 8d. per square yard for pavement with ¼in. to ⅜in. asphalte joints; these pavements last, as already stated above, twenty-one years, and that under a daily traffic of 1200 tons per yard width of road." From this it would appear that we are making a mistake in London in using such soft wood as we do for our pavements.

THE wires between St. Margaret's and the General Post-office, London, were on last Sunday afternoon and evening used for the purpose of experimenting with the teautograph—the invention of Professor Gray, of New York—the time for the experiments being selected owing to the wires being comparatively idle on Sundays. "Special instruments were fixed up at both ends, the messages transmitted being, in every respect, most successful, the instruments working without the slightest hitch over a distance of eighty-three miles. The principle of the instrument is that it automatically records an exact *fac simile* of the writing contained in messages. In the experiments yesterday the receiving pencil recorded with ease and clearness different handwritings, giving thick and thin strokes, dotting i's, and crossing t's very correctly." A correspondent writing to the *Times* points out that more than forty years ago the copying electric telegraph, invented by the late Frederick Collier Bakewell, successfully transmitted autographic messages between Brighton and London. Invisible messages, which could be rendered legible by the recipient, were also transmitted by that system. The copying electric telegraph was subsequently exhibited at the great Exhibition of 1851, and received the highest award, viz., the Council Medal. The late E. A. Cowper also invented and exhibited a writing telegraph.

A PAPER on "The Buckling and Wrinkling of Plating Supported on a Framework Under the Influence of Oblique Stresses" was recently read before the Royal Society by Mr. G. H. Bryan. The present investigation is chiefly interesting as forming an addition to the small class of soluble problems in which the question of stability arises in connection with the theory of elasticity. In a previous communication the author discussed the kind of buckling which arises when a rectangular plate has to support thrusts in its own plane, applied perpendicularly to its edges, and of sufficient magnitude to render the plane form unstable. The problem now considered is that of a sheet of plating of indefinite extent supported on equidistant parallel ribs, or on a rectangular framework formed by two such sets of ribs crossing each other, and which is compressed by thrusts applied in any direction not necessarily perpendicular or parallel to the ribs. Let the plating be supported on parallel ribs at distances $b$ apart, and let it be compressed by a thrust P—per unit length measured in the plane of the plate—in a direction making an angle $\alpha$ with the ribs. Then using C to denote the cylindrical rigidity of the surface, the conditions of instability may be summed up as follows:—(1) If $\alpha < 30$ deg., the plane form will become unstable when $P > 4 \pi^2 C \div b^2$, and wrinkles will then appear on the surface. These wrinkles will run in directions perpendicular to the direction of P—*i.e.*, at an angle 90 deg. $+ \alpha$ with the ribs, and will consist of alternate elevations and depressions, the lines separating which will be at distances $b$ apart. In other words, the wrinkles with the ribs will divide the plate into rhombi, in which the displacements will be alternately to one side and to the other of the plane form. (2) If $\alpha < 30$ deg., the same form will become unstable if $P > \pi^2 C \div b^2 \sin^2 \alpha$, and the plating will then buckle into simple corrugations running parallel to the ribs, the displaced form of the plate being a cylindrical surface, of which the section perpendicular to the ribs is a curve of sines. The corresponding results are also worked out for a plate supported on a rectangular framework. A simple rough-and-ready illustration of these results is afforded when a sheet of paper is thrown into wrinkles.

## MISCELLANEA.

A NEW lighthouse has been erected on Cape Antifer, Seine Inférieure, France. Mineral oil is used, and the light is white, with an interval of 20 seconds between each flash.

NOTICE is given that the business of the Baker Blower Engineering Company will in future be carried on by Mr. Thomas Somers, Messrs. Ambrose Firth and John Bowns having retired from the concern.

THE Maschinenbau Actien-Gesellschaft "Vulcan," of Stettin, Germany, have made arrangements with Messrs. Yarrow and Co. for the adoption of their patent water-tube boiler in some of the vessels they are now building.

THE Admiralty have awarded the contract for the supply of metallic and other asbestos jointing materials of various kinds to the United Asbestos Company, London. This is the tenth time this company has received this contract.

THE twenty-fifth annual prize competition, under the auspices of the Turners' Company, will be held, by permission of the Lord Mayor, on October 24th, 25th, and 26th, at the Mansion House. The competition this year will be in turning in wood and stone.

THE large dam across the Colorado River, work on which was begun some months since, has been completed. The dam is located three miles above the city, and it is stated 100,000-horse power will be the capacity of the electrical power transmission plant.

THE aluminium torpedo-boat which Messrs. Yarrow and Co. are constructing for the French Government is rapidly approaching completion and will be launched shortly. We gave dimensions of this vessel when describing Messrs. Yarrow's works in our issue of June 22nd.

THE following is a recipe for making a fireproof insulation in electrical wiring:—Forty proportions by weight of magnesia, 28 of tallow, 15 of pulverised asbestos, 30 of liquid glue, 15 of glycerine, and ¼ of chromate of soda or potassium; to this may be added an additional ¼ of lampblack if it is desired that it should be black.

THE Delta Metal Company have in hand orders for the propeller blades of several of her Majesty's new torpedo-boat Destroyers, to be cast in their No. 1 Delta alloy. Twelve blades have already been delivered. The tensile strength of the cast Delta metal—mean of twelve specimens—proved to be 36·45 tons per square inch, with an elongation of 20 per cent.

THE steel works now being constructed by the Donetz Forges Company at Constantinovka, in South Russia, with a capital of £400,000, will include a large Bessemer steel making plant, a rail rolling mill, foundry, forge and an engineering shop. It is hoped that the plant will be put in operation this year, as orders have already been secured for the supply of 100,000 tons of rails to the Russian State railways during 1895, 1896, and 1897.

AT the meeting of the Mersey Docks and Harbour Board, on the 19th inst., the Marine Committee recommended that the buoys on the Mersey Bar, which indicate the channel through the bar, be widened from 1000ft. to 1400ft. Mr. Crow, in proposing the adoption, said the channel's least depth was 20ft. to 25ft., so that a vessel of ordinary draught could come in at any time; and in fact, on Saturday last the Umbria, which was drawing 24ft. of water, crossed the bar at dead low water. The recommendation was adopted.

THE Home Secretary, acting under the powers of the Factory and Workshop Act, 1878, has issued an order, operative from the 5th inst., permitting male young persons of sixteen years and upwards to be employed at night in factories where the process of iron ore washing is carried on, it having been proved to the satisfaction of the right hon. gentleman that the nature of the business requires the work to be conducted throughout the night, and that such employment will not injure the health of the young persons engaged therein.

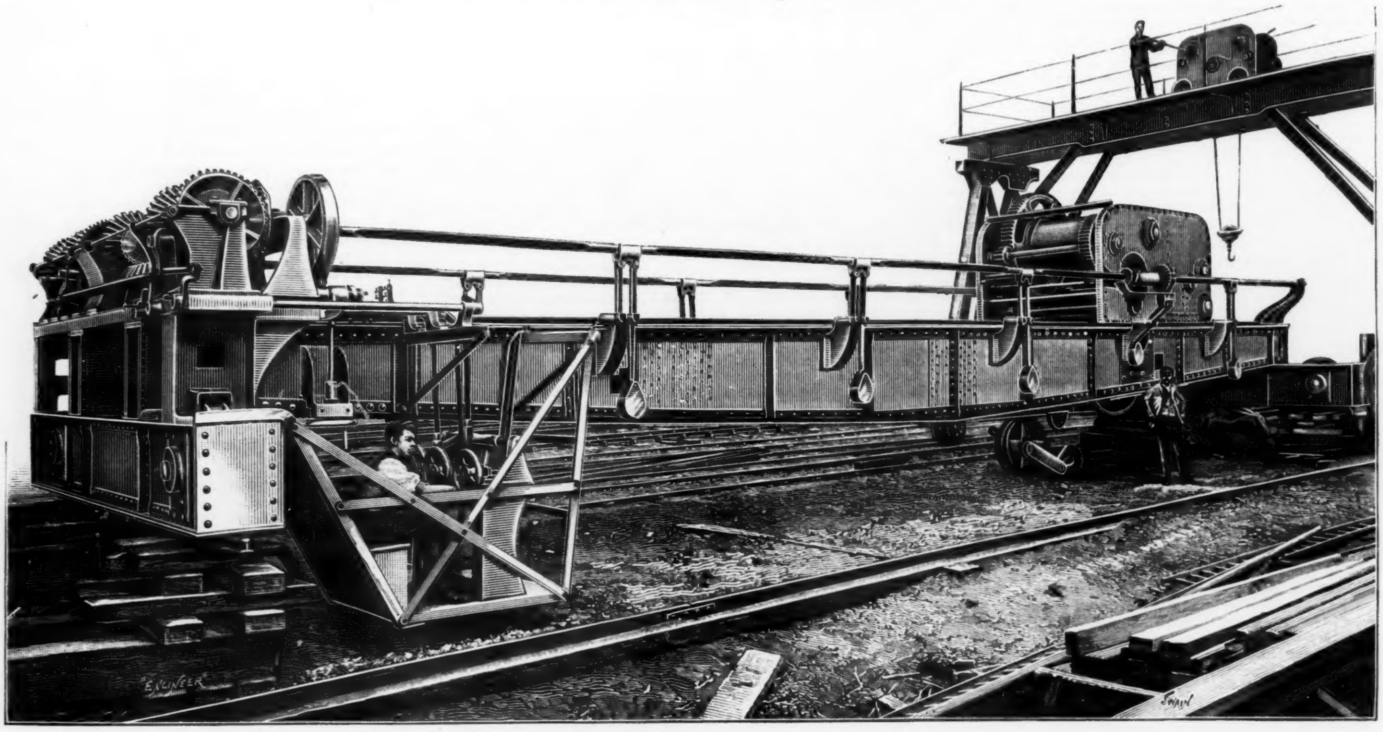
MR. BENJAMIN PICKARD, M.P., President of the Miners' Federation of Great Britain, has been presented with an illuminated address and a cheque for £752, in recognition of his services to the miners in the recent prolonged struggle. The presentation was made by Mr. Haslam, of the Derbyshire Miners' Union, and Mr. W. Ramsden, of Hourton, handed Mr. Pickard a crystal sword, remarking that "It was the sword of justice and of peace." Mr. Pickard, in reply, laid stress on the miners having secured recognition of the principle of a living wage. That obtained must now be maintained. If the miners maintained it for two years, they might be confident that the president of any Conciliation Board would decide in favour of its being decreed permanent.

THE work accomplished by the Millers' National Association in the course of the past twelve months resolves itself into a hearty co-operation with the National Transportation Association, a body which has effected tangible good for the Western manufacturer. The association, says *The Miller*, has also to its credit a great deal of work in opposing patent claims, which are reported to have been pressed more vigorously and in greater numbers last year than has been the case for a long time past. To resist the patent shark was one of the original reasons for the existence of the association, and it is clear that the shark is far from having been killed. In a discussion on this subject, Mr. Seamans, the treasurer, stated that on the file of the United States Patent Office there were about 200,000 patents which were worthless, except for "illegitimate purposes," whereby he, no doubt, meant purposes of extortion. He proposed, that for the protection of industry, a small tax should be imposed on all patents. If the patent were being worked this impost would not, he argued, be felt, but if the owner of the patent had not enough faith in or use for his invention to pay the duty, then the patent should, is was suggested, be made public property.

WITH regard to the new Act concerning the width of London streets, the *Builder* says:—"In regard to this one item of the width of streets for London, the provisions of the London Streets and Buildings Bill are miserable, and are calculated to stereotype one of the greatest mistakes that can be made in a town, both for appearance and for sanitary conditions—viz., that of having streets too narrow in comparison with the height of the houses. Chancery-lane represents what the Bill proposes as the average and usually accepted width of street for London for the future. Is that the kind of street which we ought to contemplate as the regulation width for future London streets? Sixty-three feet is the width of the eastern portion of Oxford-street, which represents very well that class of street which 'forms part of an important line of communication'; and that street, besides not looking like a first-class street according to modern ideas, is manifestly too small for its traffic; but that is rather wider than we are to expect from the London County Council's new Bill for the largest and best London streets of the future. The widest part of High Holborn is 115ft., and even there the space is often insufficient for the free progress of the traffic, partly, no doubt, in consequence of the cab-rank and one or two other obstacles in the centre, but these at the most cannot deprive the roadway practically of much more than 10ft.; say, however, that they represent the odd 15ft.; that leaves 100ft. for a road that is not in the least too wide for its position. But according to the County Council's Bill we can never have such a street as that again; we can never by any possibility have such a street as Portland-place—the only street in London which at all recalls the ample proportions of the best Paris streets."

# SIXTY-FIVE-TON OVERHEAD TRAVELLING CRANE

THE SOUTHGATE ENGINEERING COMPANY, NEW SOUTHGATE, ENGINEERS



## 65-TON OVERHEAD TRAVELLING CRANE.

THE accompanying engraving illustrates a 65-ton overhead travelling crane built for the gun factory of the naval arsenal of a foreign Government, and works inside a building 300ft. long and 60ft. wide. The crane, which is driven by square shafting, is specially designed for handling guns up to 30 c.m. bore and 40 calibres, and for placing them in and removing them from the various machines arranged along either side of the factory for which it has been constructed. Power is transmitted through a short vertical shaft and bevel gearing from the square shaft, which runs in tumbling bearings along the side of the shop and behind the driver's cage to a friction shaft carried in brackets across the ends of the main girders. These brackets are all fitted to an independent bedplate, which in its turn is fitted to the end of the main carriage. The friction shaft carries three sets of double friction cones and mitre wheels of the ordinary type. These wheels have all been made of large size, so that the friction clutches might be of as large diameters as posssible, and have big bearing surfaces.

Thus very little power is required to be applied to the screwed hand-wheels by which the clutches, through a series of levers, are put in and out of gear, and the large bearing surfaces prevent the clutches from binding. One set of friction gearing is connected through spur gearing to two of the main carriage axles, one at each end of the crane, for the purpose of travelling the whole structure. The other two sets of friction gear drive two long square shafts which run along the full length of the main girders, one on either side of the crab. One shaft travels the crab along the main girders, the other one drives the hoisting gear, and is fitted with a powerful screw brake. Both these square shafts are carried in tumbling bearings of an improved and simple type. Power is applied to all the friction clutches by means of screwed hand-wheels. These all work in brackets bolted to the top of a table casting, which is secured to the floor of the driver's cage in front of his seat. The hand-wheel for applying the brake is also close at the driver's hand, as he sits to work these other wheels, so that he has complete control of all the motions of the crane without leaving his seat. He also has an unobstructed view of the whole area of the shop over which he is travelling. The travelling crab is built with cheeks of steel plates and angles. It is so constructed that the centre of the hook can be brought very close to either wall of the shop, so that it commands nearly the whole of the space over which it travels. The girders are built of steel plates and angles, and are of box section. The long girders are each built in three pieces, and will be riveted together when the crane is erected complete in its place. The total span between rails is 57ft. 8in., and it has a travel down the building of 280ft. Total weight 54 tons.

The illustration given is from a photograph of the crane as it was erected complete in the construction yard of the builders, the Southgate Engineering Company, on the Great Northern Railway at New Southgate.

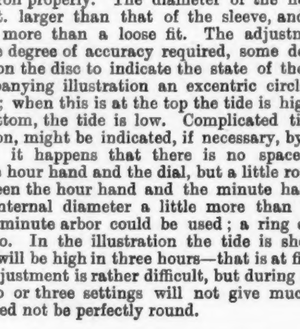
## A DOMESTIC TIDE INDICATOR.

DURING a holiday at the seaside, it is often asked: When is low water to-day? Bathing, boating, walks on the beach, and other matters depend on the state of the tide; some are trivial, and others, such as "the point of cut-off" of a rocky headland, may be of importance. The usual course is to ask a sailor, or to consult a newspaper, or "Bradshaw," "Whitaker's Almanack" being generally left at home. While the Thomson tide predicter is one of the most complicated instruments that have ever been made, the following device, by Mr. A. P. Trotter, B.A., has at least the merit of extreme simplicity, and is accurate enough for the domestic purposes of a holiday maker.

Without going into the theory of tides, it is sufficient to say that during a period of fifteen days, the tides alter about twelve hours, that is, they are about forty-eight minutes later each day. The problem is to apply a simple contrivance to a clock to lose forty-eight minutes a day. A cheap clock is better for the purpose than a good one, for the space between the hour hand and the dial is to be utilised, and this, like the noise of the tick, varies inversely as the price of the clock.

Since it is illegal to deface the Queen's coin, a disc of metal, of about the diameter and thickness of a penny, must be procured, a French penny will answer very well. Take off the hands of the clock, observe the diameter of the sleeve which carries the hour hand, and drill a hole through the disc, to make an easy fit. If the clock is personal property, the sleeve, with its wheel, may be taken out, but if the timepiece is an item of furniture in "apartments," this need not be done, for it is not absolutely necessary. The size of the hole must be adjusted so that when the sleeve makes thirty revolutions, the disc rolling on it makes twenty-nine revolutions. To test this without removing the hour wheel and sleeve would entail 360 revolutions of the minute arbor, but as no great accuracy is needed, it is sufficient to make a mark on the disc, bring this mark opposite the hour hand, and turn the hand round $2\frac{1}{2}$ times, that is, through thirty hours; the mark ought then to move, relatively to the hour hand, through the space of one hour division.

A thin disc, say of tin or cardboard, is rather too light, and is inclined to lean against the dial or the hour hand, and will fail to roll properly. The diameter of the hole is only $3\frac{1}{3}$ per cent. larger than that of the sleeve, and does not amount to more than a loose fit. The adjustment being made to the degree of accuracy required, some device must be painted on the disc to indicate the state of the tide. In the accompanying illustration an excentric circle is shown on the disc; when this is at the top the tide is high, when it is at the bottom, the tide is low. Complicated tides, as at Southampton, might be indicated, if necessary, by a special device. If it happens that there is no space available between the hour hand and the dial, but a little room is to be found between the hour hand and the minute hand, a ring having an internal diameter a little more than $12\frac{1}{3}$ times that of the minute arbor could be used; a ring cut out of tin would do. In the illustration the tide is shown to be rising, and will be high in three hours—that is at five o'clock. Accurate adjustment is rather difficult, but during a month's holiday two or three settings will not give much trouble. The hole need not be perfectly round.



## HIGH SPEED VERTICAL ENGINES.

WE illustrate on page 79 two forms of a high speed vertical engine, each being one of a series recently introduced and manufactured by Messrs. Ransomes, Sims, and Jefferies, of Ipswich and London. The engine is of the open double-acting type, and has been specially designed for driving dynamos, fans, pumps, and other high speed machinery, either coupled direct or by belt. Before finally adopting the design shown, Messrs. Ransomes have carefully studied the special requirements of high speed engine users, and they have made costly experiments to ascertain the best manner in which these requirements can be met. The engine under description is the result of their experience; a considerable number have already been supplied, and are, we are informed, giving great satisfaction. The general design of the engine will be understood from the illustration, but it may be built with the valve chest and fly-wheel reversed in position.

In calculating the strengths and wearing surfaces of the various parts, a very high boiler pressure and an ample margin of safety has been allowed for. The engines may be worked direct from the boilers of triple expansion engines without risk of breakdown or heating. All reciprocating parts are accurately balanced. The crosshead is of cast steel, and the gudgeon is so fitted that the loosening of one nut and a slight tap will release it, and admit of the examination of the brasses. The crosshead gudgeon and the crank pin are both of very large diameter, and the width of each of these bearings is equivalent to twice the diameter; the shaft bearings are also of exceptional size. All bearings are provided with screw adjustments, and can be got at without the slightest difficulty. The lubrication of all working parts is automatic and continuous; the cylinder is provided with a self-acting cup, and the crank-pin is fitted with a centrifugal oiler. This oiler and the cups at the top ends of the rods are supplied from a central oil box conveniently placed and provided with a sight-feed arrangement to each supply pipe. A splash guard, not shown in the illustration, is provided.

The engine illustrated is fitted with a throttle-valve governor on the Pickering principle, but an automatic expansion "shaft" governor—patented and manufactured by Messrs. Ransomes—is also used as shown in the larger engraving. The shaft governor acts direct upon the piston slide valve, and varies the cut-off in proportion to the load. The speed can be adjusted as desired while the engine is running with the Pickering governor, and a special attachment can be provided with the shaft governor to secure the same object. Messrs. Ransomes manufacture this engine in six standard sizes, and another series of engines with enlarged cylinders suitable for working at moderate boiler pressures.

The automatic expansion "shaft" governor is shown by Fig. 2. This governor acts directly upon the piston slide valve, and varies the cut-off in proportion to the load. The engine illustrated has a cylinder $8\frac{1}{2}$in. diameter by 8in. stroke. It is coupled to a dynamo manufactured by Messrs. Laurence, Scott, and Co., of Norwich. The electrical output is 180 ampères at 65 volts and 270 revolutions. The field magnets are constructed of magnet steel cast in one piece. The armature is built up in the usual way with charcoal iron discs, each of which is driven by three keys from the shaft. The conductors, of pure copper strip well insulated with mica, are let into slots milled in the discs.

BRITISH INSTITUTE OF PUBLIC HEALTH CONGRESS, 1894.—The general programme has been published of the above Congress, which will meet from the 25th to 31st of this month, and which will be attended by over 3000 delegates appointed by the various local authorities in the United Kingdom. The Congress will be opened by a conversazione on the evening of the 25th at King's College, and the Engineering and Building Construction Section will meet at King's College, at the undermentioned times and dates for the discussion of the papers mentioned in the programme:—Thursday, the 26th, 2 p.m. till 5 p.m.; Friday, the 27th, 10 a.m. till 12 p.m.; Monday, the 30th, 10 a.m. till 12 p.m.

ELECTRIC POWER TRANSMISSION FOR SOUTH AFRICA.—Last week, Messrs. Johnson and Phillips of Charlton, invited a few of their friends to inspect the electrical machinery they have just completed to the order of Messrs. Davis and Soper, London, for the Sheba Gold Mining Company for the transmission of 200-horse power over a distance of five miles. The generators, of which there are two, are of the new Kapp type, illustrated by us last week, but with the armatures arranged to give a two-phase current at 3300 volts. The output of each generator is 132 K. W. These machines will be worked by turbines, and at the delivery end of the line step down transformers will be used by which the current will be supplied to the motors at 100 volts.; the latter are of the Brown self-starting type. One alternator, two transformers, and one motor were shown in action at the time of the visit above mentioned. Having so recently described the new generators, it is unnecessary to say anything concerning them in detail, but it may be mentioned that an inspection of them impresses one most favourably as a remarkably simple and strong machine, which can hardly be put out of order even by short circuiting. A machine which commends itself as peculiarly adapted for work where there are no facilities for repairs, and where the attention or assistance of trained electrical engineers is not to be had.

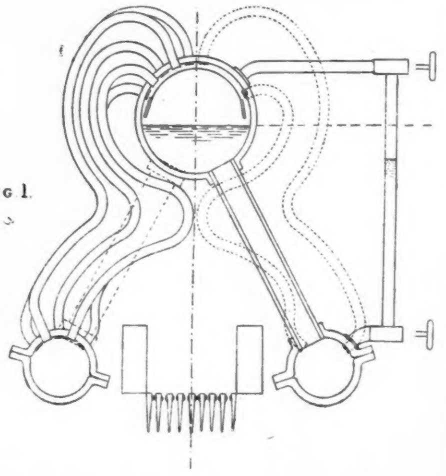
## THE INFLUENCE OF CIRCULATION ON EVAPORATIVE EFFICIENCY OF WATER-TUBE BOILERS.*

By Mr. John I. Thornycroft, F.R.S., Vice-president.

To obtain the highest evaporative duty from a given tube service, it is necessary that the contents of the tube should consist of, as far as possible, water only; and to attain this result the steam must have the freest possible egress from the tubes, and must also be carried from them by an energetic circulation of water in a constant direction. To some of the leading features which affect these conditions I would now call your attention. Considering the boilers shown in Figs. 1 and 2, if the pressure in the lower vessel—that is, at the bottom ends of the generating tubes—is due to the full depth of water in the boiler, in addition to the steam pressure, then any reduction of density in the generating tubes will all be available for causing circulation; and thus any reduction in pressure in the lower vessel, below that due to the head of water in the boiler, is a direct loss to the energy of circulation, so that variations of this pressure are of great importance. These variations can be conveniently measured by a pressure column formed of a long gauge glass connecting the steam space of the upper vessel with the lower vessel. The difference of the water-level in this glass from the water-level in the upper vessel is a direct measure of any reduction of pressure in the lower vessel.

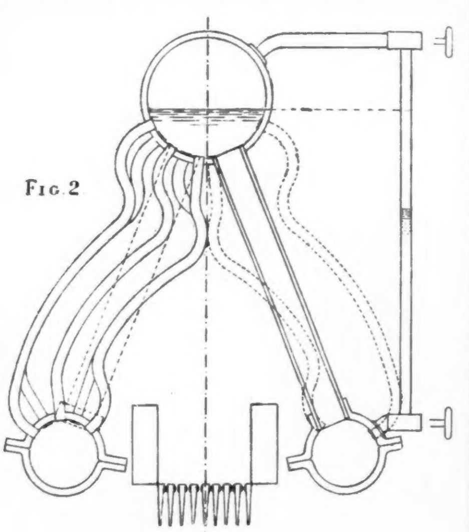
I have made experiments, taking observations from such pressure columns fitted to the boilers shown in Figs. 1 and 2, when they were working under different conditions. The rate of evaporation and steam pressure being varied for the several arrangements of boiler, which were:—(1) Generating tubes delivering above water. (2) Generating tubes delivering below water. (3) Generating tubes delivering below water—without any special downtake tubes.

Fig 1.



The curves given in diagram 3 show graphically the results of these experiments; the falls of pressure in the lower vessels are plotted as ordinates, and the rates of working as abscissæ. It will be seen that the rate of working has been taken up very high, probably more than double ordinary working, the object in doing this being to ascertain up to what rate each arrangement can be worked with safety. In the first series of curves, the results recorded are obtained from the boiler, Fig. 1, with the generating tubes delivering above water. It will be seen from the curve that, as the rate of working is increased, the pressure column falls slightly, and at an evaporation of 20 lb. of water per square foot of heating surface stands at 85 per cent. of the maximum; and by halving the working pressure the results are not sensibly changed.

Fig 2.



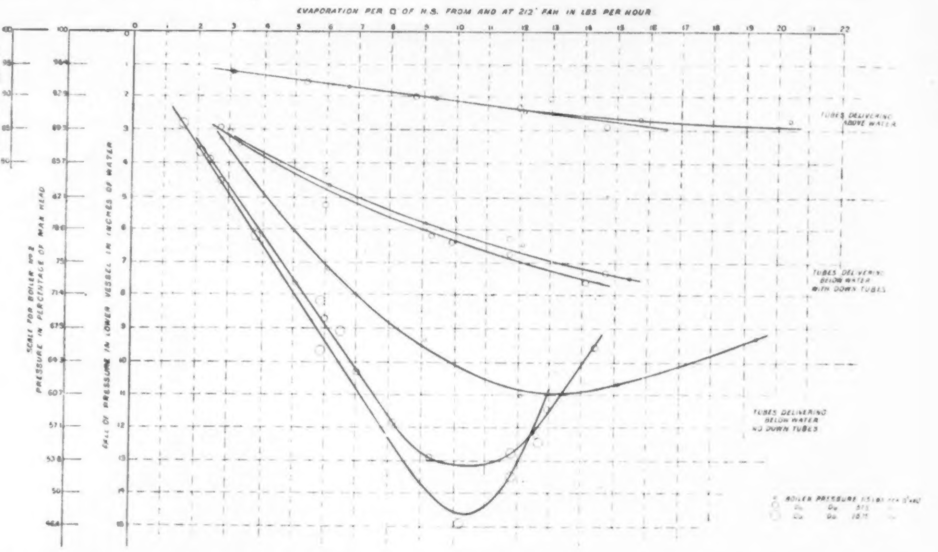
The next series of curves is taken from the boiler, Fig 2, which has the same heating surface, &c., as Fig. 1, but the top ends of the tubes deliver below water. It will be seen that the curves fall much more rapidly than the first series, and that by halving the working pressure the pressure is distinctly reduced in the lower vessel.

The third series was obtained from the boiler, Fig. 2, by plugging up the down tubes, so that some of the generating tubes had to act as down tubes for the supply of the others; the feed water all being delivered into the upper vessel. In this case the character of the curves changes from the first two series very much. A diminution in pressure of working causes the pressure column to fall very much; in the case of the pressure being only 28·75 lb. per square inch absolute, it fell to about 46 per cent. of the maximum. The most important point, however, apart from this low pressure, but a result of it, is that for any given pressure a critical rate of working is arrived at when the pressure column begins to rise again with increased rate of working, thus showing an increased pressure in the lower vessel, caused by the steam being unable to get out at the top ends of the tubes fast enough, and so comes out at the bottom ends as well. It will be seen from the curves that the lower the pressure of working the sooner this critical point is arrived at, and I found that when the evaporation was pushed beyond this critical point the tubes were not safe from overheating; but, by taking the tubes intended for downtakes, and extending their upper ends above the water surface so that water could not go down, and the steam in the lower vessel could readily get away to the separator, it was possible to increase the rate of evaporation somewhat, inasmuch as the facility for the tubes getting rid of their steam was increased.

Contrasting the different conditions of working of the water tubes in the three series of experiments I have described, and noting what slight differences these conditions may necessitate in the design of a boiler, the nearness to success which a boiler intended for hard forcing may be, and yet fail, is clearly shown.

In conclusion, I would submit that the absence of special down tubes limits to a great extent the amount to which a boiler can be safely forced, and shows that to obtain the highest rate of working with safety and efficiency these special down tubes must not be neglected; and still further, the tubes should deliver above water, as then the circulation, as I have previously shown, is double that when the tubes deliver below water. So that this rapid circulation is a most important condition for hard working.

Fig. 3.



THE JUNIOR ENGINEERING SOCIETY.—The members of this Society recently visited the electric and hydraulic installations of the Great Eastern Railway at and in the neighbourhood of Liverpool-street, by permission of the engineer, Mr. John Wilson, on whose behalf the district engineer, Mr. H. Wilmer, received the party and superintended the arrangements for their guidance over the extensive area included in the visit. The electric lighting station, situated in Norton Folgate, contains three 100-horse power and four 200-horse power compound vertical steam engines, each driving a dynamo. Steam is supplied by five Lancashire boilers working at 140 lb. pressure. The lights will consist of 212 arc lamps; and 4773 16-candle power, 272 32-candle power, and 55 50-candle power incandescent. The hydraulic engines and pumps, of which there are two sets, are placed at Bishopsgate-street low level station, and to meet the demand occasioned by the extension of the system, are about to be duplicated, as are also the two boilers and accumulator, &c. There are numerous capstans, truck hoists, parcel lifts, and cranes operated throughout the passenger stations and goods yards and warehouses, and a 50ft. diameter engine turntable has lately been connected up to be worked by hydraulic power. At the conclusion of the inspections, Mr. W. H. De Ritter, member of Council, expressed the members' acknowledgments for the reception accorded them on the occasion.

THE NORTH SEA AND BALTIC CANAL.—It appears from the latest advices of a German official Gazette that the works of the canal uniting the North Sea with the Baltic are sufficiently advanced to warrant the expectation that the new water communication may be successfully inaugurated about this time next year. The project was first introduced to the notice of the Government in 1869, but it was not until nearly twenty years after that it received the sanction of an Imperial decree. Launched under such authoritative and favourable auspices, the question of cost was the next consideration. The sum total, allowing for contingencies, which in engineering works of this character require a fairly wide margin, amounted to a little over £8,000,000. A third of this was either contributed or guaranteed by the Government, and the remainder raised by loans, bonds, and other well-known financial means available for the prosecution of national enterprises, backed up by the approval of the State and its monetary assistance. The advantages of this new waterway are of a double character. It will enable vessels of all tonnage to navigate the northern seas, without encountering the difficult, dangerous, and often tempestuous passage of the Cattegat. It will also serve the purpose of protecting, in a strategic point of view, the coast line of the country in its vicinity. It is estimated that the amount of the commercial traffic accruing from the facilities afforded by the canal will not fall far short of 12,000,000 tons.

RAILWAYS IN FORMOSA.—There are two lines of railway in Formosa, the northern and southern branches, both having their termini in the capital Tai-peh-fu. The northern branch between Twa-tu-tia—a suburb of the capital—and Kelung, a distance of 19¼ miles, now works regularly; the gap at Patu—caused by the destruction of a wooden bridge during a heavy freshet—having been filled at the end of last October by the erection of a steel bridge on stone abutments. The southern branch runs from Twa-tu-tia to the district city of Hsin Chu, a distance of 43½ miles, where the line stops, the continuation being hindered probably by the serious difficulty and expense of bridging the Tyka River. Between Fêng Shan Chi and Hsin Chu a good deal of bridge work has been done by the Chinese under a Cantonese, called the "bridge builder." The first bridge immediately south of Fêng Shan Chi consists of one span of 200ft., one span of 120ft., three spans of 50ft. each, all of steel, and six wooden spans of 30ft. each. The next bridge, at T'o Tzŭ P'u—a mile further on—consists of two steel spans 200ft. and 50ft. respectively, and a number of wooden spans. The Hung Mao Tien Bridge—a mile further on—consists of two steel spans 150ft. and 50ft. respectively, and several small timber spans. During 1893 three new engines, four passenger coaches, and six wagons were received from Birmingham, and a telephone system was installed on the northern branch. In the summer the superintendent doubled the rates, the result of which was that the traffic fell off. According to the Acting British Consul at Tamsui, there seems to have been a partial recovery since; but no information, even of the most general kind, as to the receipts of the lines is obtainable.

## LETTERS TO THE EDITOR.

(*We do not hold ourselves responsible for the opinions of our correspondents.*)

### ADAM'S BRIDGE REEF.

SIR,—A short time ago you published an interesting article, headed "Adam's Bridge Reef," describing the proposal of a London Syndicate to join India to Ceylon. In this article it is stated:—"Just about the present time the surveying ships of the Indian Government are commencing the systematic examination of the site of the proposed railway crossing, in order to further the scheme lately made public. It will be a question largely affecting the amount of the estimate for the intended bridge, should this examination result in establishing the supposition that the layer of coral along the line to be dealt with is of sufficient thickness to afford a holding for the pier piling." This statement I believe to be wrong. The Government survey ships are instructed simply to examine the Palk Strait to find out whether deep channels exist such as would enable large vessels to reach the Bay of Bengal, if a ship canal were constructed through Rameswaram Island. No instructions were given to them in connection with the railway project. The survey is intended to include only the area contained between the meridians of Point Pedro on the east and Delft Island on the west, and that portion of the Straits lying between the north coast of Ceylon and Point Calimere. This comprises all the most shoal water in the Straits, and contains an area of about 1200 square miles. Besides a detailed survey for the use of vessels at present trading to the northern ports of Ceylon and through Pamben Pass, a careful examination is being made for a channel of sufficient depth to allow ocean steamers to pass through. Fortunately, March and April are the finest months on this coast, so that the work in Palk Strait progressed rapidly. Working from Point Pedro to the westward, the survey was carried on as far as Karativo before the vessels were called to Bombay.

A glance at the Admiralty chart of the Strait shows that along this portion of the coast the former survey indicates a general depth of six to seven fathoms for from five to seven miles off shore, but with shoal patches off Karativo, and it seems probable that along the north coast of Ceylon the least depth to be met with would be five and a-half to six fathoms. The track to carry this depth passes five and a-half miles north-west of Karativo, close round Point Pedro, then south-east past Ethiopia shoal, and so to seaward. There may be another tract to seaward through the shoals north of Valvettiturai, but this is as yet only partially explored, and the few soundings obtained here by Commander Carpenter in 1887 gave a depth of five and a-half fathoms. It is evident that if the channel round Point Pedro should prove the only available one for ocean steamers, part of the advantage of a ship canal through Rameswaram Island would be lost. It is also a question whether the captains of ocean steamers would take their vessels through a channel exposed to the strength of the monsoon, whose least depth is five and a-half fathoms, with a bottom of hard sand. During the next visit of the Investigator to the Strait the survey will be continued to the northward, when it is hoped a good channel may be found. The chart of the Strait will then be drawn and the results published. This will decide the feasibility of canal project, but I cannot see how it will decide the feasibility of the railway project.

Madras, June 26th.

HENRY BEAUCHAMP,
Editor *Madras Mail.*

### THERMOMETRIC MEASUREMENTS.

SIR,—I shall feel obliged if you will allow me to give a few explanations of the method of using thermometers graduated so that equal increments and decrements of temperature correspond with equal increments and decrements of heat, for determining the differences between the quantities of heat possessed by bodies in different thermal states. In my letter of May 15th, in which I demonstrated that Thomson's absolute scale of temperatures is simply a scale in which equal increments and decrements of temperature correspond with equal increments and decrements of heat, I pointed out that $\frac{H}{T}$ represents the difference between the quantities of heat possessed by a body at temperatures T and $T - 1$, if H represents the heat added to the body during the isothermal expansion stage of the Carnot cycle at temperature T, or abstracted during the isothermal compression stage at the same temperature, and that therefore if $H = T$ thermal units, each increment or decrement of one degree of temperature would correspond with the increment or decrement of the heat possessed by the body by one thermal unit. My object in writing that letter was simply to prove that in accordance with Thomson's absolute scale of temperatures, equal increments and decrements in temperature correspond with equal increments and decrements of heat. If, instead of putting $H = T$ thermal units, we put $H = m S_v T$, thermal units, where $m$ is equal to the number of thermal units of mass of the body, and $S_v$ its specific heat at constant volume, a rise or fall of one degree of temperature would correspond with the addition of $S_v$ thermal units to each unit of mass. A thermometer is an instrument for ascertaining the variations in the thermal state of bodies from some known standard state. If, in the case of one particular substance, we know the difference between the total quantity of heat possessed by the substance in two known thermal states, for instance, in the case of water in the thermal states of melting ice and boiling water, the same difference in the case of another body will be in the ratio of its specific heat at constant volume to that of water. If the specific heat of water is adopted as the standard, the difference between the heat possessed by the water at temperatures $t_1$ and $t_2$ will be equal to $(t_2 - t_1)$ J per unit of mass, and by any other substance $S_v$ $(t_2 - t_1)$ J.

## THE KINETIC THEORY OF GASES.

SIR,—Referring to the formula, given in my letter in THE ENGINEER, of the 13th of April last, for the pressure of a gas, viz.: $P = \frac{m \bar{u}}{t\, l^2} \times \frac{N \bar{u}\, t}{2l}$; where $m$ is the mass of a single molecule; N the number of molecules, $\bar{u}$ the velocity of their mean square resolved parallel to one of the sides, $l$, units in length of the cube box containing the gas, and $t$ is *half* the time occupied by the impact of a molecule. I think it will be generally admitted that the expression $\frac{m \bar{u}}{t\, l^2}$ in the above equation correctly represents the pressure on the side $l^2$ of the box due to the impact of a single molecule during the time $t$. It will also, no doubt, be generally admitted that this expression multiplied by the number of molecules in contact with the plane during the time $t$ will give the total pressure on the plane at the time. But it may be thought that the number in contact with the plane should be $\frac{N \bar{u} \times 2t}{2l} = \frac{N \bar{u}\, t}{l}$, and not $\frac{N \bar{u}\, t}{2l}$ as given above, since each molecule is in contact with the plane during the time $2t$. The object of this letter is to show that this is not the case.

In investigating this problem, Waterston commences by supposing that a small *rigid* elastic plane is supported by a succession of impacts from molecules striking against it immediataly below its centre of gravity, the plane rising and falling under the influence of the impact and gravity through some indefinitely short distance. Thus one necessary condition, owing to the plane being rigid is, that to secure what Waterston terms statical equilibrium, one impact must be completed before the next commences. Obviously, instead of a succession of single molecules impinging at regular intervals, there may be a large number of molecules impinging simultaneously, followed by another set of molecules, and so on, the impact of each set being finished before the next set impinge. For the plane to be kept in equilibrium by a succession of such impacts, one commencing as the other leaves off, it is clear that the upward acceleration of the *plane* due to the mean pressure during impact must be exactly equal to the downward acceleration due to gravity. Thus we may suppose each impact divided into four periods. At first contact of the molecule with the plane, the pressure commencing at zero will rapidly rise to its mean value, the downward acceleration during this, the first period, will be in excess of the upward acceleration. During the second period, the pressure increases from its mean to its maximum value, and the upward acceleration will be in excess of the downward. The third and fourth periods will correspond with the second and first respectively, both as regards pressure and acceleration. If the plane is at rest at the highest point of an oscillation at the commencement of an impact, during the first period it will fall, during the second it will gradually be brought to rest, during the third it will rise, and during the fourth period its upward velocity will be retarded and the plane will come to rest at the end of this period in precisely the same position at which contact first commenced. And this action will be repeated at each successive impact when the plane is in statical equilibrium.

If N be the number of molecules in a cube box, the top of which is an oscillating rigid plane in statical equilibrium, $N^{\frac{1}{3}}$ will be the number in a line parallel to any side of the box at any instant of time, and $N^{\frac{2}{3}}$ will be the number of molecules in each layer. As half the molecules in each horizontal layer will be moving in an upward, and half in a downward direction, $\frac{1}{2} N^{\frac{2}{3}}$ will be the number in contact with the plane at any instant. Also, $\frac{1}{2} N^{\frac{1}{3}}$ will be the number of molecules in a vertical line or elementary vertical column having an upward motion. As the molecules are supposed to impinge at intervals of $2t$ against the plane, the time intervals between the molecules having an upward velocity in each elementary column must be $2t$. If T equal the time for a molecule to move with the given velocity $u$ through a distance $l$, the length of the side of the cube box, then $2t = \frac{T}{\frac{1}{2} N^{\frac{1}{3}}}$, or $t = \frac{T}{N^{\frac{1}{3}}}$. Again, the number of impacts made by a single molecule in unit time against the plane is $\frac{\bar{u}}{2l}$, and the total number of impacts will be $\frac{N \bar{u}}{2l}$. Let $x$ be some factor which when multiplied by $\frac{N \bar{u}}{2l}$ will give the number of molecules in contact with the plane at any instant, then

$$\frac{N \bar{u}\, x}{2l} = \tfrac{1}{2} N^{\frac{2}{3}}$$

$$\text{or } x = \frac{l}{N^{\frac{1}{3}} \bar{u}}.$$

But $\frac{l}{\bar{u}}$ is obviously equal to T, the time taken by a molecule to move through the distance $l$ with a velocity $\bar{u}$. Hence:

$$x = \frac{T}{N^{\frac{1}{3}}} = t.$$

Hence $\frac{N \bar{u}\, t}{2l}$ is the number of molecules in contact with the plane at any instant. It has been tacitly assumed in the above proof that the duration of an impact is insignificant when compared with the time of the free path of any molecule.

If with Waterston we suppose that the impacts between the molecules and the plane occur when the plane has acquired a certain downward velocity, then there must be an interval of time between the impacts, during which no molecules are in contact with it. In this case if $t$ equal *half* the time of impact and $(v + g\,t)$ the velocity of the molecule and $-\left(\frac{v}{n} + g\,t\right)$ that of the plane at impact—the mass of the plane being $n$ times as great as that of the molecule—then from the action of gravity and pressure the velocities of both plane and molecule will be zero at the end of time $t$, and after another interval $t$ the plane and molecule will separate with the same velocities with which they impinged, but, of course, with opposite signs.

Now let T be the interval from the end of one impact to the beginning of the next; during which time there are no molecules in contact with the plane. This interval of time must equal the time required by gravity to destroy and reproduce the velocity $\left(\frac{v}{n} - g\,t\right)$ of the plane. Hence

$$T = \frac{2\left(\frac{v}{n} - g\,t\right)}{g} = \frac{2\,v}{g\,n} - 2\,t \quad . \quad . \quad . \quad . \quad (1)$$

Now the value of T depends upon the velocity of the impinging molecule, and by making $v$ very great, $n$ being constant, and reducing proportionately the number of molecules T may be made as great as we like. But in this problem we require its minimum value only which can be shown to be equal to $2\,t$.

For if a succession of molecules at time intervals of $2t$ apart impinge against a plane in the manner described, it is obvious that by choosing a suitable velocity for the molecules the plane can be kept in statical equilibrium. In this case, $2\,t$ is the time of impact, and $T = 2t$. the interval from the end of one impact to the beginning of the next. If now a change is made and T becomes less than $2\,t$, then either the molecules must be closer together than before or their velocity must be increased; in either case the statical equilibrium of the plane would be disturbed, and the plane would rise to a higher level. On the other hand, if T is made greater than $2\,t$, which can only be effected by either increasing the distances between the molecules or decreasing their velocity, then the plane will fall. Then since T can be neither greater nor less than $2\,t$, it must be equal to $2\,t$. Substituting this value of $2\,t$ in equation (1) we get

$$T = \frac{v}{g\,n} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (2)$$

and the number of impacts per unit of time will be

$$\frac{g\,n}{v} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (3)$$

Waterston gives $\frac{2\,v}{g\,n}$ as the interval between the impacts, but in obtaining this value he has omitted to take into consideration the effect of gravity on the plane during the time of impact. That is he considers each impact to be an absolutely instantaneous phenomenon, which is a physical impossibility. And here I should like to take the opportunity of correcting an error contained in my letter of April last on this subject, regarding the *vis viva* required to raise a plane of mass $n$ to a height of $\frac{2\,w^2}{g\,n^2}$. The amount required should be $\frac{4\,w^2}{n}$, as given by Lord Rayleigh in his note to page 19 of Waterston's paper, and not $\frac{2\,w^2}{n}$ as stated by me.

But the proof given for the former value is inadmissible as the action of gravity during the time of impact of the molecule with the plane is omitted. The simplest method of finding the expenditure of *vis viva* under the given conditions is as follows. The *vis viva* expended in lifting a body through a given distance in the same as the body would acquire in falling from rest through the same distance. Here $\frac{2\,w^2}{g\,n^2}$ is the height and $n$ the mass of the body, hence the *vis viva* acquired in falling will be

$$n \times \left(\sqrt{2\,g \times \frac{2\,w^2}{g\,n^2}}\right)^2 = \frac{4\,w^2}{n}.$$

The above correction does not however affect the result given by Waterston for the ratio of the *vis viva* expended in the act of increasing the volume of a gas with the increment of the *vis viva* required to support the increased volume. For—Waterston, page 22—the increment of *vis viva* required to support an increase of volume equal to $\frac{2\,w^2}{g\,n^2}$ is—

$$\Delta^3\,v^2 \times \frac{2\,w^2}{g\,n^2} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (4)$$

where $\Delta^3$ is the density and $v$ is the velocity of the mean square without regard to direction; $w$ is the velocity resolved normal to the plane and $n$ is the mass of the plane, the mass of the molecule being taken as unity. To find the value of $g\,n$ in the above expression we have from (3) the number of impacts in unit of time $= \frac{g\,n}{w}$. Also the impacts in unit of time is given by the expression $\frac{1}{2}\,\Delta^3 w$—Waterston, page 21. Hence

$$\frac{g\,n}{w} = \tfrac{1}{2}\,\Delta^3\,w,$$

$$\text{or } g\,n = \tfrac{1}{2}\,\Delta^3\,w^2 = \tfrac{1}{6}\,\Delta^3\,v^2.$$

Substituting this value of $g\,n$ in (4) and remembering that $w^2 = \frac{1}{3}\,v^2$, the increment becomes $\frac{4\,v^2}{n}$. But $\frac{4w^2}{n} = \frac{4\,v^2}{3\,n}$ is the *vis viva* expended in increasing the volume by $\frac{2\,w^2}{g\,n}$. Hence the ratio of this to $\frac{4\,v^2}{n}$, the *vis viva* required to support the increased volume, is manifestly $\frac{1}{3}$, and it follows from this that the amount of *vis viva* required to produce an increment of molecular *vis viva* in the two cases of constant pressure and constant volume is in the ratio of 4 : 3.

C. E. BASEVI.

8, Norfolk-square, W., July 19.h.

## *re* ENTROPY, MODERN HEAT, ETC.

SIR,—Dr. Lodge and others of your contributors have, in the writer's humble opinion, laboured to invest this matter of entropy with much unnecessary obscurity. As a matter of fact, a perfectly sufficient treatise on the theory of thermodynamics may be written without introducing the term entropy or its congeners at all. The thermal condition of a body is defined by the volume, temperature, and pressure of a given quantity of it. If any one of these quantities be given, a relation subsists between the remaining two, which, for practical engineering purposes, depends simply on certain constants determinable with more or less accuracy experimentally.

Now, the entropy (*sic*) of a body is simply the expression of a relation between any two of the three quantities—pressure, volume, and temperature.

If such of your readers who feel any confusion of ideas, due to the introduction of the term entropy, &c., will contrive to forget all that Dr. Lodge has written with reference to it, and take the above simple view of the matter, the writer thinks they will be benefited. Whatever view they may take they will have finally, for practical purposes, to come back to the fundamental and readily measurable quantities—temperature, volume, and pressure.

HENRY CHERRY.

Putney, S.W. July 25th.

## TO ADVERTISERS.

SIR,—On opening my ENGINEER of 20th inst. I was pleased to learn that I was not alone in complaining against the indifference of advertisers, and to find that others consider the present system of advertising most uncharitable and reprehensible.

"Another of the Applicants" remarks very justly on the matter of testimonials. For myself, I have a decided aversion to mine being spread broadcast, not knowing into whose hands they fall; and under the present system we cannot know, for if they be returned it is generally without note or comment, and we remain in ignorance of their destination beyond the post-mark on the wrapper. I hold it is better never to send testimonials until specially asked to do so, and in no case to send stamped envelopes for reply.

There is another system fast gaining ground, and which to my mind is more to be deprecated than the indifference of which we complain—that is, the demand for a stated number of recent testimonials. If a man possess testimonials of one, two, or three years ago, they ought to be considered sufficient. It is not to be expected that an applicant can, without a feeling of being and appearing troublesome, importune his late employers for testimonials for a specific appointment, when perhaps the applicant already holds one or more from the said employers. To a man with any sense of decorum such a thing is most distasteful. Again, in the majority of cases testimonials are asked for, yet the applicant is likely to be told in the course of a personal interview, if he be fortunate enough to obtain one, "Your testimonials are very good, but really we don't attach much importance to testimonials." To what, then, is importance attached? Let some habitual advertiser enlighten us. Under the existing system, draughtsmen are the greatest sufferers. Why? Is it because they are as plentiful as blackberries, or more so, that they can be looked over so indifferently? When I mentioned draughtsmen in my former letter, I meant draughtsmen, whose cause I voice—and not draughtsmen (?), otherwise fledglings of the Board or local schools of art, but staid men with experience matured by years of practical work.

In my younger days—and I am not by any means an old man yet—draughtsmen and works managers were deferred to as superior beings, and treated accordingly. Alas! now-a-days the draughtsman is looked upon as a necessary evil, and I fear that in many cases the works manager is not always regarded as a valuable adjunct to an establishment. At any rate, events which have come under my experience go far to prove conclusively what I state.

To return to the point; all that we ask is that our communications be acknowledged, if not individually, then collectively. The suggestions contained in my previous letter, if adopted, will answer our purpose very well, and will involve neither trouble nor expense to the *bonâ fide* advertiser.

In conclusion, I fail to see the necessity of advertisers occupying from four to eight weeks or more in selecting a candidate for any appointment. A week or ten days should be ample in the case of a draughtsman, and a fortnight or three weeks for a works manager. The manager can take care of himself—a handful of days may be neither here nor there to him, but to the draughtsman the case is different. The stipend accorded to him even in good times is not conducive to grandiose pecuniosity, and when he is unfortunately thrown out of gear, the purse is not always in that plethoric condition that he can afford to "hang about," Micawber like, waiting for something to turn up. Trusting that my suggestions may in one way or another be adopted by those who have any sympathy at all for the applicants, I am,

Newcastle-upon-Tyne, July 24th. ONE OF THE APPLICANTS.

## IRON PLOUGHS IN MADRAS.

SIR,—I enclose a letter from the Deputy Director of Agriculture, Madras, on the subject of iron ploughs. It seems a pity that Sweden should get the benefit of this trade. What are our English manufacturers about that they do not compete with their Swedish brethren in British markets?

HENRY BEAUCHAMP,
Editor *Madras Mail*.

Madras, July 4th.

Gentlemen,—I have the honour to draw your attention to the fact that during the past season there has sprung up a very brisk demand for heavy iron ploughs all around Bellary, and that the demand that existed could not be met at the time. This has led certain local dealers to order considerable numbers of ploughs from Sweden, where the manufacturers grant very liberal discount on all considerable orders. That the demand during the next season, which may be expected to open about November next, will be considerable there is every reason to believe. I have myself heard of orders for as many as 140 large ploughs being placed within the last few days, and from what I gathered at Bellary many more orders will very soon be registered there. At present the bulk of these orders are being placed in Sweden, and considering the excellence of the ploughs supplied, and the prices at which they can, in consequence of the very liberal discount given, be supplied, this is only natural. It therefore appears to me that if the manufacturers of Madras desire to obtain a share of this business, their prices must be such as will compete with those for imported articles. I am able to give, for your information, the subjoined figures, based on an actually invoiced lot of ploughs now lying in Bellary, which will enable you to judge at what rates the favourite patterns could be profitably laid down there, after allowing a reasonable profit in the transaction:—

| | Ofverum's Buck Plough. | | | |
|---|---|---|---|---|
| Particulars. | No. 1 | N. 2 | No. 16 | |
| Initial cost in Sweden .. .. .. | 26 75 | 33 5 | 41 5 | Shillings net |
| Packing and freight to Madras at 12·5 per cent.. .. .. .. .. | 3 35 | 4·2 | 5·2 | „ |
| | 30·1 | 37 7 | 46 7 | |
| Duty 5 per cent. .. .. .. .. | 1·5 | 1·9 | 2 3 | „ |
| Approximate cost ex-ship at Madras .. .. .. .. .. .. | 31·6 | 39 6 | 49·0 | „ |
| = to Rs. at 1s. 1d. per Re. .. .. | 29 2 | 36·5 | 45·3 | Rupees |
| Landing and forwarding to Bellary at 9 per cent. .. .. .. | 2·6 | 3·2 | 4·1 | „ |
| Net cost at Bellary.. .. .. .. | 31 8 | 39 7 | 49 4 | |
| Add for interest pending realisation, fitting, &c , 10 per cent.. | 3 2 | 4·0 | 4·9 | „ |
| Gross price Bellary Rs... .. .. | 35 0 | 43·7 | 54·3 | |

All except the last item are rates based on an actual set of transactions, the percentages for freight and packing, and for landing and forwarding being slightly in excess of the actuals in the case referred to.

The prices at present asked by the only holder of the ploughs in Bellary are far in excess of the rates given above, but the ryots, knowing they have four or five months before them in which to make arrangements for importing what they require, are in several cases combining to send orders to Sweden at their own risk through commission agents, who are agreeing to work for a very small fixed commission on each plough imported, by which plan, unless exchange falls heavily, they will obtain those ploughs probably at lower rates than those I give above.

## A VOLUNTEER FLEET.

SIR,—I have noticed some correspondence in your paper respecting a "Volunteer Fleet," and your correspondents do not appear to be aware that there was in existence for several years a corps of "Royal Naval Artillery Volunteers," with brigades at London, Brighton, Hastings, Portsmouth, Plymouth, Bristol, Swansea, Liverpool, Glasgow, Hull, Yarmouth, and other ports. The training was hard, consisting of heavy gun, rifle, cutlass, and pistol practice, rowing, sail drill, knotting and splicing, and a certain amount of seamanship was taught, while the officers had to pass severe examinations.

Drills and tuition were frequent all the year round, and a fortnight's training in one of Her Majesty's gunboats formed part of the annual curriculum. Both officers and men threw themselves heart and soul into the training necessary to gain a thorough knowledge of the duties performed in the service, and that a high state of efficiency was attained was amply testified to by successive admirals of Naval Reserve.

But in spite of this the Government, for some reasons best known to themselves, disbanded the corps about two years ago, in spite of the protests of the very efficient members at that time enrolled. That a corps of this character, composed of men with a knowledge of the coast and of sailing, would be very useful in time of war, especially in the present under-manned condition of the navy, is a fact upon which there can scarcely be two opinions, but as long as it is the policy of successive Governments to discourage and hinder all volunteer movements, and to throw cold water on all schemes of volunteer defence, I very much doubt whether young men will be found to devote the time and energy necessary to efficiency in a somewhat arduous branch of Her Majesty's service.

ERNEST WHITE.

Wolverhampton, 19th July.

SIR,—With no adequate naval reserve of able seamen, and no considerable number of British sailors in our ports without employment, it seems to me that the present conditions are a national scandal, which at any time may become a national peril.

I should like to know how many aliens are now employed in her Majesty's Navy. The education of a man, to become capable of serving on a British warship, cannot be imparted in a day, or even in a month.

If Mr. J. C. Merryweather, who started this correspondence in the influential columns of THE ENGINEER, has any remedy worked out in detail, it is incumbent upon him, as a patriotic business man, to lay the same before your readers.

F. A. DINHAM.

141, Mount View-road, Crouch Hill, N., July 24th.

IT appears from the annual report of the Comptroller of Patents that in 1893 applications were made for more than 25,000 patents, 19,400 designs, and 8675 trade marks.

## TO CORRESPONDENTS.

**Registered Telegraphic Address, "ENGINEER NEWSPAPER, LONDON."**

*** *In order to avoid trouble and confusion, we find it necessary to inform correspondents that letters of inquiry addressed to the public, and intended for insertion in this column, must in all cases be accompanied by a large envelope legibly directed by the writer to himself, and bearing a penny postage stamp, in order that answers received by us may be forwarded to their destination. No notice can be taken of communications which do not comply with these instructions.*

*** *We cannot undertake to return drawings or manuscripts; we must therefore request correspondents to keep copies.*

*** *All letters intended for insertion in* THE ENGINEER, *or containing questions, should be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever can be taken of anonymous communications.*

### CAST IRON FOR GRINDING MILL PLATES.

(*To the Editor of The Engineer.*)

SIR,—Can any reader inform me the name of the brand or brands of pig iron which, when cast into grinding mill plates, will give a thoroughly hard surface? I have tried several mixtures and can get them quite hard in the low places, but the ridges, which should be hardest, always seem to be softer than the body of the casting.

J. B.

July 24th.

### RURAL WATER SUPPLY PLANT.

(*To the Editor of The Engineer.*)

SIR,—In working out a scheme to provide a very small agricultural village with a common pump for the supply of good drinking water, the only practicable position for the storage system is 500 yards away—where the water is found—and 20ft. below the level of village street, where the pump is wanted. Would an ordinary suction pump, with a small galvanised iron pipe to the cistern, draw the water the 500 yards, and at the same time lift it the 20ft. required, without being too hard work for the villagers to fill their pails? If so, what type of pump would be most reliable and what size suction pipe would it require?

This village has any amount of water too hard for drinking, and at present has to collect rain water for this purpose, while the only alternative source to that suggested would be a deep boring, which it could not afford to pay for. Advice on this would greatly oblige

July 21st. RURAL SANITARY INSPECTOR.

### SUBSCRIPTIONS.

THE ENGINEER *can be Kad, oy order, from any newsagent in town or country at the various railway stations; or it can, if preferred, be supplied direct from the office on the following terms (paid in advance):—*

*Half-yearly (including double number)* .. .. £0 14s. 6d.
*Yearly (including two double numbers)*.. .. £1 9s. 0d.

*If credit occur, an extra charge of two shillings and sixpence per annum will be made.* THE ENGINEER *is registered for transmission abroad.*

*A complete set of* THE ENGINEER *can be had on application.*

*In consequence of the reduction of postage on newspapers to one uniform rate for any destination outside the United Kingdom, Foreign Subscriptions will, until further notice, be received at the rates given below. Foreign Subscribers paying in advance at these rates will receive* THE ENGINEER *weekly and post free. Subscriptions sent by Post-office Order must be accompanied by letter of advice to the Publisher.*

THIN PAPER COPIES—
*Half-yearly* .. .. .. .. .. .. .. .. .. .. £0 18s. 0d.
*Yearly* .. .. .. .. .. .. .. .. .. .. .. £1 16s. 0d.
THICK PAPER COPIES—
*Half-yearly* .. .. .. .. .. .. .. .. .. .. £1 0s. 8d.
*Yearly* .. .. .. .. .. .. .. .. .. .. .. £2 0s. 6d.

READING CASES.—*The Publisher has in stock reading cases which will hold thirteen copies of* THE ENGINEER. *Price 2s. 6d. each.*

### ADVERTISEMENTS.

*** *The charge for advertisements of four lines and under is three shillings, for every two lines afterwards one shilling and sixpence; odd lines are charged one shilling. The line averages seven words. When an advertisement measures an inch or more, the charge is ten shillings per inch. All single advertisements from the country must be accompanied by a Post-office Order in payment. Alternate Advertisements will be inserted with all practical regularity, but regularity cannot be guaranteed in any such case. All except weekly advertisements are taken subject to this condition.*

*Prices for Displayed Advertisements in "ordinary" and "special" positions will be sent on application.*

**Advertisements cannot be inserted unless delivered before Six o'clock on Thursday evening; and in consequence of the necessity for going to press early with a portion of the edition, ALTERATIONS to standing advertisements should arrive not later than Three o'clock on Wednesday afternoon in each week.**

*Letters relating to Advertisements and the Publishing Department of the paper are to be addressed to the Publisher, Mr. Sydney White; all other letters to be addressed to the Editor of* THE ENGINEER.

## MEETINGS NEXT WEEK.

THE JUNIOR ENGINEERING SOCIETY.—Saturday, July 28th Visit the Windsor and Eton Waterworks and the Windsor Gasworks. Train leaves Waterloo at 9.38 a.m.

LIVERPOOL ENGINEERING SOCIETY.—Friday and Saturday, August 3rd and 4th. Excursion to the Oswestry and Filter Beds, Masonry Dam and Tower at Lake Vyrnwy, by the kind permission of the Water Engineer of Liverpool, Mr. Joseph Parry, M. Inst. C.E.

NEWCASTLE-UPON-TYNE ASSOCIATION OF STUDENTS OF THE INSTITUTION OF CIVIL ENGINEERS.—Friday, August 3rd, by invitation of Mr. C. A. Harrison, M.I.C.E., President of the Association. Visit to the widenings of the North-Eastern Railway between Pelaw and Felling, and also between Central Station and Manors.

# THE ENGINEER.

*JULY 27, 1894.*

## THE UTILISATION OF THE NILE.

WE learn that the International Technical Commission appointed by the Egyptian Government to advise on the proposals for the utilisation of the Nile has brought its labours to a close, and its report, after three months' investigation, is now in the hands of the Government. We had hoped that the publication of this report would ere this have enabled us to deal with the subject at first hand; but as we have already indicated, delay seems to be the inevitable result of this appeal to a commission, and we must await a still further revelation before we are in a position to proceed with our examination of the details of such project as may be selected by the Government.

In a recent article in the *Nineteenth Century* on "Nile Reservoirs and Philæ," Sir Benjamin Baker, the British Commissioner, draws aside, partially, the curtain of official reticence, and from him we learn authoritatively that the Commission has not been quite unanimous in its verdict. The whole of the Commissioners, it turns out, were unanimous in rejecting the Waddy Rayan project, and in recommending the construction of a reservoir in the Valley of the Nile itself, but here the unanimity ceased. The majority of the Commission were convinced that it would be practically impossible to place the dam elsewhere than at the head of the Assowan Cataract below Philæ, but to this the French Commissioner could not agree, and he continued his objections to the whole of the proposals.

He thought that European engineers and contractors should be invited to study the Nile reservoir question, and submit competitive designs for the work; but the majority of the Commission were satisfied that this proceeding would only be useful if delay were the object, as the question had been exhaustively considered by the engineers of the Egyptian Government for four years. And moreover, the members of the Commission having exceptional advantages for obtaining information, and after going over the whole of the ground, were themselves unable to suggest any reasonable alternative.

The French Commissioners made, it is true, certain suggestions as to alternative schemes; but in the end approximate estimates showed that, even if practicable, the cost of the cheapest of their alternatives would be millions more than that of the Philæ dam. Neither could his colleagues nor the Government engineer accept the type of dam proposed by him, which was an open dam, or *barrage-mobile*, made up of isolated narrow piers, 16ft. apart and 80ft. high. Truly a weak and card-house style of construction, open to easy destruction by convulsions of nature, enemies, or revolutionists; and under which, considering that it was to uphold 3000 million of tons of water, it would be scarcely fair to ask the people of a country to live. Despite the fact that the question of the temples was not referred to the Commission at all, the French members rejected the Philæ site *in toto* on the sole ground of their presence; and we are inclined to read between the lines a political bias as influencing his objection more than any archæological conservatism.

Sir Benjamin Baker notes with satisfaction that their French colleague did not base his objections to the Philæ scheme on engineering grounds, and sees in his disagreement the advantage which the more inquisitorial criticism of a talented dissentient would bring with it, inasmuch as his opposition to the scheme would tend to make his scrutiny more thorough and searching. In consequence the Egyptian Government is complimented on the more complete attainment of their aim in having an ample and unbiassed examination of the entire question, with a view to the more complete elicitation of the whole truth; and the triumphant result announced, that no engineering or financial blot has been discovered in the project of their engineers for the dam at Philæ.

As regards details of construction, however, several modifications of designs were required by the British and Italian Commissioners with a view to increased security, and these were accepted without reserve as improvements on the original designs. The openings through the dam for the discharge of the Nile floods, which may reach the enormous quantity of half-a-million cubic feet per second, have been reduced in size, and correspondingly increased in number, so that the force and mass of the issuing water may be more distributed. These openings are to be lined with cast iron 1½in. thick, so that no stone can be torn out and the work destroyed piecemeal by the water at a high velocity. The width of base of the dam, moreover, is to be increased, so that the pressure on the masonry will be less, and the factor of safety greater than on any existing structure of the kind, thus doubling the security of the structure at a cost of about £400,000, or about 25 per cent. of the original estimate. On these points we shall have some remarks to make when in possession of details, which may be expected with the report of the Commission. Meanwhile, with our present information, we concur in thinking that a dam must be built at Philæ, and that with the least possible delay, as in the event of the occurrence of one or two "bad Niles," and the heavy consequent loss of summer crops, the moral responsibility of the advisers of delay will be beyond dispute, and it might be better, as the English Commissioner puts it, that the stones of Philæ Temple should be broken up for concrete than that Egypt should be involved in financial ruin, so long as his countrymen have a leading voice in the management of its affairs.

Very little light is thrown on the proposal for raising the level of the temple, which seems to have been Sir Benjamin Baker's own idea. He writes:—"As regards the Philæ Temple, the matter stands thus: The Under-Secretary of State and the Commissioners have stated, in no equivocal terms, their appreciation of the importance of the question. The British Commissioner has personally examined the ruins, and is in possession of plans showing every detail. He is of opinion that the solidity of their construction, the absence of windows, and the solid rock foundation, render it far easier to raise these temples bodily than any of the buildings he has seen so dealt with in America. The well-drilled garrison at Assowan would be delighted to work the elevating screws with military precision, and no doubt can be entertained as to the success of the operation. Half the wonder and admiration excited by the monumental works of ancient Egypt arises from the magnitude of the masses handled and transported by the Old Egyptians, rather than from their artistic merit. From the archæological point of view, the condition of the temples when raised would be unchanged, as every stone would remain as originally laid by the builders, and as shown on every drawing and photograph. From the artistic point of view the appearance would be enhanced, because the temples would rise out of a wide, placid lake, whereas when now visited by tourists, the Nile is low, the stream insignificant, and the Philæ island appears to stand in a hollow."

In this matter the writer, we fear, claims too much. We think—no doubt with others—that too much may be made of the archæological and artistic value of the Philæ temples; but we fear that the removal would cause sentimental as well as physical injury to the buildings, that raising them would be more costly than is expected, and that when so raised they would lose their artistic value for several months of the year, when the lake was drained off to meet the agricultural requirements of the country. We still hold to the idea, and shall do so till it is proved practically untenable, of isolating the site of the temples by a series of subsidiary dams, thus obtaining the most suitable site for the reservoir while preserving the archæological remains intact.

On the other hand, it should be noted that the signatories to a recently-published letter to the Earl of Kimberley assign to this part of the subject an importance which they are loth to attach to the great and humane problem, the solution of which it was the object of the Commission to achieve. The world will respect and attach value to the expression of opinion of the representatives of art and of literature and dilletanti science; but it will also assign a place to the recommendations of those who would in the best way accomplish a work which the amelioration of millions demands. These recommendations are made by men who, with knowledge of the country and of the requirements, and who have expressed deliberate opinions as to means of providing for them, opinions which are backed by the responsibility which a man accepts when in saying a task is a possible and necessary one, he virtually undertakes it.

## THE COUNTY OF LONDON.

THE work done by the London County Council, and what London has to pay for it, has just formed the subject of an elaborate address delivered by the present chairman of the Council, Sir John Hutton. Professedly a review of the year ending last March, the chairman's address nevertheless travelled over the five years, and more, during which the County Council has been in existence. Dealing in the first instance with the year just past, it was shown that the gross debt for which the Council has to account exceeds £33,000,000, a sum which is about equal to the entire rateable value of what is called the "county," a term including the City as well as the wider area lying outside it. The word "metropolis" is sometimes employed in a popular sense as meaning all London. At other times it is understood to be London minus the City. The term "county" is convenient as covering both areas, only it happens that the City is a county of itself. Perhaps "London" is the most convenient phrase, and we find it generally employed by Sir John Hutton, though the official headquarters at Spring Gardens bear the appellation of the "County Hall," and everything must needs be in harmony with that designation. After realising the fact that the gross debt of the county is very nearly equal to its rateable value, there is the further consideration that while the rateable value is growing, so also is the debt. The net amount of this encumbrance is under £19,000,000; but this itself is an increase of £1,200,000 in the space of five years. When the budget of the Council was brought up last April, the chairman of the Finance Committee, Mr. Evan Spicer, stated that the expenditure of the Council was bound to grow year by year. Only let the incidence of taxation be changed, and then various improvements and schemes, now "looming in the distance," and involving large expenditure, will be carried out. What then will be the debt, and what the rate, nobody seems prepared to say.

It will be observed that throughout his address Sir John Hutton speaks of a rate of 13d. in the pound. That is true for the year which ended on March 31st, but the rate which London now bears is one of 14½d. The rate of last year, at 13d., was itself an advance of a halfpenny on the year before. The Council is spending at the rate of £3,000,000 per annum, of which one-half arises out of the debt, and it is only fair to observe that half a million goes in the shape of grants to Boards of Guardians. Exchequer contributions come in aid of revenue, the sum raised by rates last year being thus made £1,783,000. The last rate levied by the Metropolitan Board was 10d. in the pound, or 3d. less than the impost of last year, and more than 4d. under that of the current year. But the Council is every way bigger than the late Board. It is adding house to house to accommodate its continually increasing number of officials, and there are seventeen hundred workmen in its employ, with all the appropriate accompaniments of buildings and plant. Thousands a-year are spent in rent, and the only remedy for this, which Sir J. Hutton describes as "wilful waste," is the erection of a huge municipal palace to house all the central officials under one roof. Let the waterworks be transferred to the County Council, and the tramways, with possibly the

Thames Conservancy, and not one palace but two or three may be wanted. But the Council would like to have the police, and they even propose to go into the pawnbroking business. The "Universal Provider" is a Lilliputian compared with these giants of the municipality. There is nothing they are not prepared to undertake, and that on the largest scale. Already the duties of the Council are so multifarious that we only wonder how all the work is done, even with the aid of 444 officials, permanent or temporary, in and about Spring-gardens, besides others elsewhere. We are less surprised at the money that is spent, for that is a comparatively easy process. Establishment charges exceed £107,000 per annum, and the "services" take £666,000 in the year.

But can all this last, and whither is London going? We do not say there is nothing to show for the money. It is true the County Council did not construct the main drainage, nor the Victoria Embankment, nor the Holborn Viaduct, nor the Tower Bridge. Sir J. Hutton says that five years of the Council's work and policy have "left their mark upon London." We should say that nowhere was this more conspicuous than in the rate-book. Still, there is something to be seen elsewhere. The Council has a squadron of sludge ships on the Thames, discharging some 40,000 tons of residuum per week in the deeps beyond the Nore. The river is unquestionably improved, but this would have been the case had the Council never come into existence, for the plans which have proved so successful in purifying the Thames were initiated by the Metropolitan Board years ago, though that body was stupid enough to half decry its own work. In the matter of parks and open spaces, the Council has done well, and deserves commendation. It promises something in the shape of bridges by-and-bye. The subaqueous tunnel at Blackwall is described as making "fairly satisfactory progress." The reconstruction of Vauxhall Bridge is to be included in the Council's Improvement Bill next year. Lambeth Bridge is to come afterwards, and perhaps will tumble down in the meantime. But in regard to many metropolitan improvements, the Council is holding its hand, until "betterment" is granted, and until the basis of taxation is altered. The Fire Brigade has been strengthened, but the Committee having charge of that department have thought it prudent "to deal cautiously" with the comprehensive report suggesting additional protection from fire in London generally, involving a capital expenditure of £100,000, and an ultimate increase of £30,000 per annum for maintenance. It was always the unfortunate policy of the Metropolitan Board to starve the Fire Brigade. It is to be hoped that the Council will eschew so dangerous a policy. There has been an immense improvement in the Brigade, but it seems sometimes as if the force was scarcely equal to such a contingency as may possibly arise. A powerful Fire Brigade is essential to the very existence of London.

We cannot pretend to go over all the topics comprehended in the work of the London County Council. How such a body can ask for more to do, is only explicable on the ground that the request is for work that will "pay," as in the case of the water supply and the tramways. We can also conceive that the acquisition of power has charms for the Council, so that to multiply the legions in its employ feeds a kind of municipal ambition. The parks and open spaces require a staff of 700, and the present strength of the Fire Brigade is 846. If the Council on some particular day were to muster all its forces in Hyde Park, and have a species of review, the spectators would probably be astonished—and might entertain a feeling of thankfulness that the County Council rate was no higher than it is. That it is destined to be still higher seems inevitable, unless the elections next year should bring about some change in the policy that is pursued.

### THE MANCHESTER AND SHEFFIELD RAILWAY EXTENSION.

THE Manchester, Sheffield, and Lincolnshire Railway is one of the most interesting of the British lines at the present time, because it has in view the construction of the greatest extent of main line, and also because it has before it the early completion of that undertaking, which will be of vast importance to several systems of railway. It has already expended some £32,154,774 on its lines and works, and it has before it the expenditure of £11,646,714, of which the London extension claims the larger proportion. Even in the present year it is the official estimate that £500,000 will need to be expended on that great line, so that it is evident that the rate of expenditure after the contracts are let must be rapid. Last half-year the total capital expenditure of the Manchester and Sheffield Company was £226,954, after allowing for the receipts of a sum that had been invested in the Hull Docks, which have passed into the possession of the North-Eastern Railway. Of the amount just named, there was expended £89,050 on lines and works open for traffic; and the further sum of £17,252 was spent on working stock—most of the latter being for additional locomotives; whilst in subscriptions to other railways such as the Cheshire lines, in which the company is interested, £65,681 net was expended; the remainder of the capital expenditure being on docks and allied special items, chiefly in the Grimsby district. As the total estimated expenditure for the current half-year is £845,000—including, of course, the large amount on the London extension, it is evident that there will be for the Manchester and Sheffield a large current capital expenditure for some time to come. But its income of late has been an increasing one, the past half-year showing a total increase for the parent line, apart from its joint lines, of £67,579. The half year now entered on should show even better results, because it will contrast with the worst known in railway history. But at the same time there has been of late rather a rapid increase in the expenditure. The Manchester and Sheffield has now before it the making of the extension on which so much of its future depends. There is no doubt that it will in the meantime derive benefit from the extension it has made into the Nottinghamshire and Chesterfield district, whilst the vast expenditure that will be made on its London extension should give it some revenue in the course of construction. But there is no doubt that it will need the full development of the resources of the company to enable it to complete that great line to the Metropolitan Railway, though any revival of trade such as some expect will lighten the load, and will help forward the completion of that great link in the chain of communication between Lancashire and Lincolnshire, and the metropolis.

### THE SITUATION IN THE COALFIELD.

PERHAPS the best thing that can be said about the arrangement made in the coalfield is that it seems to please neither party. An agreement, which affords both parties ground to grumble, gives evidence that it is not one-sided. This also suggests a rough kind of equity in its main points, and affords, therefore, some promise of permanency. It is no secret that the coalowners were gravely divided upon the crucial question as what is known as the "living wage." This has been the point upon which Mr. Pickard and the other miners' leaders have persistently and consistently insisted during and since the prolonged strike of last autumn. It was the point which the employers said could not be conceded, and no doubt the arrangement is in the nature of an experiment, an experiment about which a very influential number of the coalowners are very dubious. The employers' representatives on the Conciliation Board urge that the principle is only to be recognised for two years, but many hold with Mr. Bidder, Q.C., that "a principle recognised for ten minutes is a recognised principle," and that conceded now it can never be withdrawn. It is further contended that the conditions of colliery working vary so much in different coalfields, and even in parts of the same coalfield, that one coalowner may work profitably where another cannot make a profit at all. Since the arrangement was come to, leading coalowners, both in Yorkshire and Derbyshire, have been saying severe things about it. They all, however, admit that the surety of two years' peace is worth some sacrifice, and make up their minds to give the arrangement a fair trial. On the other side the men are not at all enthusiastic. They object *in toto* to the 10 per cent. reduction, which may be taken as Mr. Pickard's sweetening of "a living wage Bill" for the employers. It is not surprising that the men should take this attitude. They have been taught to shout no reduction against every demand made for the reopening of the wages question, and now when they are told that the first step towards obtaining quiet work and the recognition of a minimum wage is a reduction of 10 per cent. from what they are now receiving, they openly express dissatisfaction and discontent. At the same time they admit the importance of the agreement, particularly in regard to the minimum rate of wages being taken at so high a level as has been arranged. On the whole, there is little reason to doubt that the agreement will be loyally tried on both sides. The manufacturing and general public are glad of any agreement which puts strife beyond doubt for two years, and if at the end of that time some method to continue amicable relations in the coalfield cannot be devised, the result will augur little for the good feeling entertained between capital and labour in this great industry.

### INTERNATIONAL INLAND NAVIGATION CONGRESS.

THE Sixth Congress was opened at the Hague on Monday, the 23rd of July, and will continue during the week. Excursions have been arranged for visiting Rotterdam and the Hook of Holland; Amsterdam and the new dock at the entrance to the Canal at Ymuiden; to Lake Haarlem; to the new docks at the mouth of the Meuse and the Wahal; to the Zuyder Zee and the Island of Wit and to Zwalle. On Sunday the members of the Congress were received by the Committee of Organisation at the Botanic Gardens; on Monday a reception was given by the Minister of the Waterstaat; and on Thursday an official dinner is to take place at Schevingen. The English Section is represented by Sir Edwin Jenkinson and Mr. Philip Stanhope, M.P., who appear officially; by Mr. Vernon Harcourt; Mr. W. H. Wheeler; Mr. L. B. Wells; Mr. Hunter, of the Manchester Ship Canal; Mr. Wake and others, numbering about 25. America will have 200 members, who have all come over as representing the Institution of American Engineers. There are 150 French names on the list; 250 German; 40 Russian; and in smaller numbers Italians, Austrians, &c., making a total of about 700. The papers which have been sent in to be read include: "Taxes and Tolls on Canals in Belgium," by M. A. Dufourny; "Tides and Navigable Waterways in France," by M. Renaud; "Taxes on Canals," by A. K. Dura; "Organisation of Traction on Canals," by M. A. De Breviet; "The Port of Amsterdam," by T. A. Schuurman;" "The Port of Rotterdam," by C. T. de Tough; "The Equipment of the Interior Ports of Navigation," by M. Monet and M. Dardenne; "Means of Preventing Stoppages by Ice," by A. A. Bekaar and T. Nelemans; and Reports on the same subject by M. Camére and P. Rigaux; "Traction and Propulsion on Canals and Canalised Rivers," by M. B. de Mas and T. Hirsch; "The Cataracts of the Dnieper," by M. V. E. Timunoff. Abstracts of these papers will be given in a future number.

### ENGINEERING CONTRACTS FOR AUSTRALIA.

BRIDGE work and other constructive engineers doing a colonial business are much affected by a new clause just inserted in the regulation of Government contracts with South Australia. It is to the effect that no delivery will be acknowledged without the certificate in writing of the engineer-in-chief that the materials have been delivered in proper condition, and the fact that they have been approved by the consulting engineer in England is not, in the future, to be considered as evidence. Nor is it to be accepted as implying that any particular quantity of work has been executed. Indeed, the Government now enact that "it shall not in any way relieve the contractor from any of his liabilities under the terms of contract." This involves an entirely new departure in colonial contracting. Hitherto, any bridge or other engineering work ordered for the South Australian and other Governments have been tested and passed by the Government inspector at the makers' works in England or elsewhere. Now, however, all this is to be changed, and acceptance is to depend upon inspection at the other end. Why the necessity should have arisen for this serious alteration of policy it is difficult to see. Certain it is that the new regulation will be very irksome to contractors, and must in the long run cause the Government of South Australia to have to pay in the future a higher price for its engineering requirements. The matter is of the more importance since railway extension is just now the order of the day in certain of the Australian colonies outside South Australia, and some of the other Governments may follow the example of South Australia. Representations should be made to the Government at Adelaide by English engineers, with a view to inducing them to reconsider the position.

## LITERATURE.

*The Twenty-third Annual Report of the Railroad and Warehouse Commission of Illinois.* H. W. Rokker, State Printer and Binder, Springfield, Illinois. 1894.

THIS Report for 1893 is now published in book form, and can be obtained free on application to the publisher. Though naturally confined mainly to matters of local interest, it nevertheless brings to light certain facts with regard to American railroads and railroad practice which are worth reproducing.

The permanent-way equipment of English roads has very properly been taken by the Commissioners as a standard wherewith to compare those of Illinois. Referring to the importance of the block system and double tracks, the Report says:—"Our views in regard to the importance of safety devices of this character are substantiated by comparative statistics, which show that about five and a-half times as many people are killed in this country as in England, and the reason, in our judgment, is this: In England, 57 per cent. of the roads are double tracks, while in this country the proportion is only 5·5 per cent. In England, nearly 90 per cent. of the railroad mileage is protected by block systems, while only 5 per cent. is so protected in this country; but on the mileage in this country protected by block systems, the percentage of accidents is quite as low as in England." The State of Illinois has 10,427 miles of road in operation, of which only 400 miles are equipped with "block signaling devices which are especially constructed;" but a considerable percentage of the total mileage is protected by "block systems operated by means of telegraph train order signals," which will probably remain in use for some time to come—until, as the report says, "the traffic conditions warrant and demand special devices for train protection."

In 1893, 9,300,000 more passengers were carried over Illinois roads than during the previous year, and the total number of fatalities and injuries shows an increase; but relative to the number carried there is a decrease. This must be considered a creditable showing, when the enormous difficulties of dealing with the World's Fair traffic are considered. The fatalities and injuries to employés show a considerable increase, however; thus in 1892 for every 305 employés there was one death, and one injury for every 38; in 1893 one death occurred for every 292 employés, and one injury for every 27.

A very primitive conditions of affairs still obtains on a few of the roads, even in a comparatively densely-populated State like Illinois. For instance, the road of the Indiana, Illinois Southern, is, say the consulting engineers of the Commission, laid with cross rails, 35 lb. to the yard, of various lengths up to 30ft., "and much worn, shivered, and bent." The fish-plates were originally 21in. long, but many of them have been broken in service till they are only 3in. long. At this length "they are connected by a bolt inserted between the rail ends, and the nut tightened." The road is used largely for coal transport, and it is not surprising to learn that the derailments of gondola cars, having a load capacity of 30 tons, are frequent, even though the schedule is only 8½ miles an hour. The schedule for passenger trains was 15 miles an hour, but for both freight and passenger service the Commission have ordered a 25 per cent. reduction. Finally, the usual form of station building is old box car bodies.

In this report interesting data of the cost of hauling passengers and freight on the various lines is given. The average cost of carrying one passenger one mile, in cents, is 2·386; on the Grand Tower Cape Girardeau Railroad this cost reaches no less than 5·302, whilst on the Lake Shore, Michigan Southern it is reduced to 1·028. The average cost of carrying one ton of freight one mile, in cents, is ·68,291. On the Indiana and Illinois Southern, referred to before, to do this costs 2·337 cents, whilst one ton can be hauled a mile on the Lake Erie and Western for ·336 cents.

*The Zambesi Basin and Nyassaland.* By DANIEL J. RANKIN, F.R.S.G.S., M.R.A.S. With Maps and Illustrations. William Blackwood and Sons, Edinburgh and London.

THIS book consists of descriptions of expeditions made by the author at various times in those regions of Africa expressed by the terms Zambesi Basin and Nyassaland. The opening chapters are devoted to an account of an expedition joined by Mr. Rankin at the request of Captain Foot, who, having been appointed first British Consul for Central Africa, started from Quillimane in October, 1883, with the intention of reaching Lake Nyassa. How and why the party failed to get there is very graphically described, and Mr. Rankin's pages give a very clear idea of the dangers to be faced and the difficulties to be overcome by the pioneers of a new colony through the hostility of the natives, as well as from the obstacles presented by the natural features of the country. In later expeditions these drawbacks, incidental to all early colonisers, were complicated by the hostile attitude assumed towards the British by the Portuguese—an attitude which threatened to take on such formidable proportions that at one time it seemed probable that the expedition would have to be abandoned, owing to the forcible detention of its leaders. This was four years ago, however, and Mr. Rankin is able now to report a much more satisfactory state of feeling. He is, moreover, very much impressed with the advantages offered by the Zambesi Basin as a field for emigration, which may, he thinks, with great usefulness be directed thither. He points out that nothing tends so effectually and rapidly to develope the commerce and civilisation of new countries—always assuming them to be possessed of latent resources—as cheap water-carriage; and a glance at the map given in this work shows what a limitless horizon is open to the future of Central Africa on this account. With comparatively few miles of road, there exists a good water-way, reaching through Lakes Nyassa, Tanganyika, and Nyanza, and on through the Nile from Chinde to Alexandria—a natural feature the importance of which can scarcely be over-estimated in any scheme for opening-up the country. At a time like the present, when everything South African is invested with unusual interest, and when Africa, according to many, is the El Dorado of the future, all works on the subject are likely to be received with respectful attention; and Mr. Rankin's book should form no exception to the rule. His long residence in the country, his keen observation and wide experience of both natives and settlers, qualify him to pronounce with authority on many points in dispute, as well as to correct some of the errors which exist in the minds of those to whom *Central* Africa, at any rate, is still little more than a name.

## THE ANTWERP EXHIBITION.

(*From our Special Commissioner.*)

ALL British exhibits in the Machinery Hall which were in working order at the end of May were described in THE ENGINEER of June 1st. Several others are now ready, and as some of them are attracting a good deal of attention, it will be well to mention them before pointing out novelties in machinery of Belgian or German make.

The Linotype, though it is extensively used in England, seems quite unknown here, and many English visitors will probably see it at work in Antwerp for the first time. Though originally invented twenty years ago, the makers have continued to introduce small changes and additions; and they say that the machine now exhibited is able, owing to recent improvements, to do thirty per cent. more work than the one which was illustrated in THE ENGINEER a few years since. Its main features are the same, and it may be described as a type-setting, type-casting, and type-distributing machine. The operator sits in front of a key-board, like that of a type-writer, but larger. Above the key-board is a case containing matrices of all the letters or characters used. Each matrix is a small flat plate of brass, having the letter which is to be cast in a groove at the side, whilst the upper end has a series of teeth cut in it, like the key of a lever lock. Spare matrix-magazines can be inserted when it is desired to work different sizes of type with the same machine. By depressing one of the finger-keys the operator causes the corresponding matrix to slide down from the magazine and assume an upright position on an assembling block to his left. A separate box contains wedge-shaped distance pieces, which are brought into position by a bar, like the spacing-bar of a type-writer. Any length of line up to 5½in. can be produced. The operator can see the matrices as they come into position, and when the line is ready the distance pieces are pressed up, so as to ensure equal spacing, and the whole is then turned towards a mould wheel, behind which is a melting pot containing a special type metal, consisting of a mixture of lead, tin, and antimony, with a small amount of bismuth. The mould, on arriving opposite a slot leading to the melting-pot, is automatically locked, the pressure of a lever forces a plunger into the melting-pot, causing enough metal to pass through the groove to cast the line. The metal in the pot is kept fluid by three Bunsen gas burners, consuming ten feet per hour. The cast line, automatically pared by knives to an exact length and thickness, is again brought where it can be seen by the compositor, who has meanwhile been setting the matrices for the next line, and the spacing pieces return to their own box, whilst the matrices are first lifted vertically to the top of the magazine, and then pass along a steel bar, fitted with ribs or wards, in which the teeth at the top of each matrix enter. As these differ in each letter or character they are only released when over the mouth leading to their proper place in the magazine.

By a recent modification the knives can be set to cut the lines slightly narrower at the bottom than at the edge which bears the type, thereby enabling the Linotypes to be used for circular printing machines. As much as 16,000 ens per hour have been turned out by one machine, but the usual rate is 8000 to 11,000. The machine, in working order, weighs about 17 cwt., and can be driven by a quarter horse-power, though half horse-power is recommended. The advantages of being able to keep matter in type, and of remelting the metal directly it is no longer required, are obvious; and also the fact that when the same line is required a number of times it can be recast without being reset. Several leading London and provincial papers printed by this process form part of the exhibit. The exhibitors say that they have 450 men engaged solely on the manufacture of these machines. Adjoining the stand of the Linotype Company is that of the Steel Forging and Ball Bearing Company, of Chancery-lane and Wandsworth. The products of this company are a combination of three inventions: the manufacture of the balls, their hardening, and their application. The balls are made by a vertical rolling machine, the one shown at Antwerp being from the manufactory of Sir J. Whitworth and Co. It can be used not only for balls but for fish bolts, taper pins, plugs and similar articles. Dies, to the form of the articles required, are set by gauge an exact distance apart, and a reciprocating motion is given to them by means of racks, the length of whose travel can be regulated as required: then with three or four strokes up and down the ball, pin, or other object is rolled, with a smooth, shining surface, and exact to gauge. When balls are being made, the machine can produce a hundred a minute. The sizes most generally used are ¼in. to ⅜in. diameter, and the makers guarantee for these an accuracy of one ten-thousandth of an inch.

The hardening of the balls and other articles is not shown at the Exhibition, but the company state that it consists firstly in a special converting or carburising furnace, in which objects made of soft, tough, Bessemer steel, or even of iron, can be converted into a hard steel, high in carbon, and suitable for cutting tools. Those parts which are to be left soft are simply painted over with a preparation. By this means the piece can be more readily brought to its required shape before hardening, and this need only take place on the surface, or on part of the surface, leaving the non-wearing parts, and the whole of the interior soft, and consequently tough. The second part of the hardening process consists in a double bath, in which the object under treatment is first plunged into brine, and then direct into oil, without coming in contact with the air. The dies for rolling the balls, &c., are prepared in this way; and the exhibitors show files and other objects which have been made of iron or soft steel, and hardened in this manner.

The third invention of this company is the method of arranging the balls which form the bearing. In ordinary bearings of this description the balls frequently run in grooves, thus causing a tendency to jam. Even when flat surfaces are used, the same balls are required to take both radial and end-thrust pressure, when the vehicle, be it tram car or bicycle, is going round a curve. This must necessarily cause a grinding action, cut the bearing surface, and render the balls no longer spherical. In the bearings shown the balls are arranged in cages, which keeps them in place; small cages, with openings at the sides, being provided to take the lateral thrust. For tram cars, instead of large balls, rows of four or five ⅜in. balls are used for the vertical pressure. One of these bearings, which has run 16,000 miles in Philadelphia, forms part of this exhibit, and does not show any signs of wear. A small model to illustrate the working of cable cars is also shown.

Messrs. Smith and Coventry, of Manchester, have a large display of machine tools, the most conspicuous being a horizontal and vertical milling machine. This instrument has a table 10ft. long by 3ft. 6in. wide, and a bed 15ft. long. The milling cutter is 6in. diameter by 12in. wide. The machine exhibited was ordered by a German firm, and similar, but with 18ft. bed, are now being made for the Cie. Industrielle Electrique, and for Messrs. Siemens Bros., of Greenwich.

Another heavy machine is a 5ft. radial drill. The one shown is fitted with a clutch motion, reversing on the spindle, so that it can be used for tapping.

The boring and turning mill is a strong and well-designed tool. The object to be turned is bolted to a revolving table 4ft. 6in. in diameter, driven by very powerful gearing. There are two cutters, with independent feed, each driven by friction wheels, and a quadrant on either side to set the angle of the tool.

They also exhibit a very handy tool, called "Quince's six-spindle drill." This has six drill arms set round a central disc, so that each may contain a different sized drill or tap; and any one may be brought into use by simply turning the disc. This machine is especially intended for small works, such as electrical appliances, bicycle fittings, &c.

A 9in. capstan-lathe for turning and chasing bolts, &c., is a very powerful machine. Five tools are set round the capstan, and by revolving this any one can be brought into position. The same firm show several other lathes, a key-seater, and a good deal of smaller machinery, including a duplex brass-finishing or cock-turning lathe. This machine consists of two complete and independent lathes on one bed, and it is so arranged that plugs and barrels of brass cocks or taps may simultaneously be turned and bored to any desired taper, so as to ensure accurate fitting. Pressed steel axle-boxes, made by the Steel Railway Journal Box Company, Limited, of Manchester, are also exhibited on this stand, and seem capable of standing any amount of hard usage.

Messrs. Tangyes Limited do not make a very large display; they only show two gas engines. They are both on the Otto principle, Pinkney's patent. The larger one is a 30 horse power nominal, 73 actual; the smaller 3-horse power nominal and 6 actual. Both are self-starting. The smaller one is driving a Siemens dynamo, but the larger one is not doing any work. Both are supplied with "antipulsators." These take the place of the gas bags which are generally used with gas engines, and are a much neater arrangement. A diaphragm of india-rubber is stretched over a cast iron pan, which is then placed with the india-rubber side towards the wall. The connections are made in the same way as with a gas bag.

Tilghman's sand-blast apparatus is another British exhibit which is a good deal noticed. An improved form of the original invention, adapted for cleaning castings, was recently described and illustrated in THE ENGINEER; but those shown here are only being used for engraving on glass.

The Central Cyclone Company shows a disintegrator and a pulveriser, both at work. The disintegrator beats the substance to be treated through steel screens, so that the fineness of the product is regulated by the size of the mesh. In the pulveriser the beaters grind and throw up the material fed into the hopper of the machine, when all that has been reduced to powder is drawn up by an exhauster into a bin or collector. Particles which have not been ground fine are too heavy to be drawn up, so fall back for further treatment.

The Hardy Patent Pick Company, of Sheffield, shows the well-known "Devil" disintegrator, which took first prize at the Royal Agricultural Show at Plymouth in 1890. They also exhibit their new "Multiple Grinder." This is a series of four drums, each 2½in. wide, and with internal diameters varying from 10in. to 18in. These drums are in one casing, and each is provided with four beaters, the same shaft running through the whole machine. The material to be ground first enters the smallest chamber, and is gradually driven into the second, third and fourth. As the speed of the beaters increases with the diameter, hard pieces which are not pulverised in the first chamber are ground with increased force in each successive one.

Another exhibit of the same company is the "Magnetic Separator," a machine for removing iron or steel from grain, bones, coal, or any other substance. It consists of a wrought iron cylinder 4ft. long set at an angle slightly out of the horizontal. Twelve magnets placed round the circumference are connected with a dynamo, the connection being intercepted when they arrive at the top of the machine. A tray, supported from the outside, passes through the cylinder near the top. As every piece would have to pass 120 times over the magnets, it is impossible that any should escape; in fact it is found that all iron is usually intercepted within 8in. of the upper end of the machine. The magnets are sufficiently powerful to hold pieces weighing up to 18 lb. The dynamo requires 1½-horse power, and ¼-horse power is needed to revolve the cylinder.

The Hardy Pick Company also exhibits picks and shovels of various descriptions, and some boring machines for coal.

Messrs. Copley, Turner, and Co., Limited, of Middlesbrough, show one of their Harris Feed Water Filters, and a bottle with grease and other impurities extracted by it from the feed-water of the Cunard steamer Campania. They also exhibit a series of pile-shoes, all made of chilled cast iron, with wrought iron straps cast in. These vary in weight from 11 lb. to 99 lb., the larger ones being 21½in. long by 4in. wide; the point is wedge-shaped, and tapers towards one end. This shoe is very well designed for keeping the joints of sheet piling close.

Both in the British and the general machine gallery there are still a few exhibits which are not quite ready. Though the authorities had refused to receive anything more after the end of May, it is perhaps as well that they have not adhered strictly to this rule, for one interesting German machine, a decided novelty, only arrived in the building this month. I propose to send you particulars of this and other German machinery exhibits next week.

## LAUNCH OF H.M.S. ECLIPSE.

THE first vessel of the new naval programme, H M.S. Eclipse—one out of nine cruisers of the second class, three of which are building in the Government dockyards, and the remainder in private establishments—was successfully launched at Portsmouth on the 19th instant. It is just seven months since her first keel-plate was laid.

As a material improvement, in many respects, upon the Astræa type, a few remarks may be made upon her construction. She is wholly of steel, with the exception of the stern-post, rudder frame, and ram-shaped stem, which, as is usually the case, are strong phosphor bronze castings. The framing is a combination of the bracket and transverse systems throughout the length of the double bottom, but before and abaft it, and above the protective deck, the frames are formed of "Z" bars, with intermediate angle frames worked between them above the protective deck. The double bottom extends for a length of about 152ft., and is well subdivided into water-tight compartments, but the water-tight flats to magazines and shell-rooms practically extend the double bottom well towards the ends of the ship. A strongly built protective deck, whose maximum thickness is 2½in., extending throughout the whole length, affords protection to the vital parts, such as magazines, shell-rooms, and machinery, the cylinders of the latter being further protected from shell fire by a sloping Harvey-armoured coaming. The armoured deck is shaped like that of the Vulcan, with a curve so deep as to extend down far over the sides, thus protecting a vertical streak of some 6ft. or 7ft. in width. The angle which this amoured deck makes with the side plating is about 45 deg., hence the 2½in. plates with which it is covered present a horizontal thickness of 3½in. of steel to the fire of the enemy. Thus the difference in displacement between the 5600 tons of the Eclipse and the 4360 tons of the Astræa—viz., 1240 tons—is not only distributed over the longer and broader hull, but has given an extra thickness of nearly ¾in. diagonally through the steel armour—a very important consideration indeed. The French cruisers of corresponding type have a protective deck of about 2⅜in.

The Eclipse has a balanced rudder, which can be actuated by hand power below the protective deck, and by steam power from the bridge, conning tower, and steam steering engine compartment. The steam steering gear is sufficiently powerful to put the helm over from hard-a-port to hard-a-starboard and *vice versâ*, or through a total angle of 70 deg., in thirty seconds, when the vessel is proceeding at full speed of 19¼ knots, with a pressure in the steam pipes not exceeding 100 lb., and the engines exhausting into the atmosphere.

The conning tower is built of 6in. nickel steel armour, the top plate being 1in. thick; the upper part will be fitted with hinged covers all round for sighting purposes. The after shelter deck and forecastle will be connected by a fore-and-aft bridge. Two steel masts with wooden pole topmasts will be fitted, but only slight sail power will be provided.

The engines, which are under construction in the yard, will be of the triple expansion type, designed to develope 9600 and 8000 indicated horse-power, with and without forced draught respectively. In each of the two boiler rooms, four single-ended cylindrical boilers will be placed, any one of which may be used independently of the other, with steam up to 155 lb. 1000 tons of coal can be carried.

The dimensions, &c., are as follows:—Length, 350ft.; beam, 53ft. 6in.; draught, forward, 19ft. 6in; aft, 21ft. 6in.; displacement, when fully equipped, 5600 tons. She will be sheathed with teak, and coppered. Anticipated speed, 19·5 knots. The armament will consist of five 6in. quick-firing guns, and six 4·7in. quick-firing guns, which will be carried on the upper and forecastle decks, sponson ports being constructed so as to afford a better end-on fire than is obtainable in the Astræa class. The minor armament will contain eight 12-pounder quick-firing guns, one 3-pounder Hotchkiss, and four ·45in. Maxims. Three torpedo tubes will be fitted, and ten 18in. torpedoes will be carried. The total complement of officers and men will be 436.

THE railways between La Guaira and Caracas and Puerto Cabello and Valencia, Venezuela—in the hands of British companies—are in full activity; but the works on the Central Railway have been discontinued since the failure of Messrs. J. E. and M. Clarke and Co. Costly bridges have been carried away by the flooding of the rivers over which they were constructed, and the enterprise is reduced to plying between Caracas and Petare, a town twelve miles distant; but an agent has arrived at Caracas, with a view of coming to an arrangement with the Government for the resumption of the work. The German or Great Railway of Venezuela was inaugurated on 1st February last, and according to the British Consul at Caracas, this line will be a great boon to Caracas, Valencia, and the intermediate towns of El Consego, La Victoria, Turmero, and Maracay, as well as to at least half-a-dozen more towns of less importance.

# THE "PETIT JOURNAL" ROAD CARRIAGE COMPETITION.

(*By our Special Commissioner.*)

PARIS, Wednesday, 18th July.

IN my last letter I stated that lots would be drawn at the office of the *Petit Journal* to decide which carriages were to run upon each particular route. I will not trouble your readers with mere list of numbers, as possibly all the carriages may not arrive although entered.

The public exhibition of the vehicles took place on Wednesday, the 18th inst.,, and soon after noon crowds of people collected at the Rond-Point D'Inkermann, at Neuilly, making it difficult to approach the carriages. Twenty-six vehicles were present, differing greatly in size and form. The Daimler motor was very well represented by the two firms Panhard et Levassor and Les Fils de Peugeot Frères. My first impression as to the entire absence of smell of this motor when working has become considerably modified. The fact is, that in such a building as that used for testing the motor to which I previously referred, the air is still and the products of combustion, rising in a vertical pipe which terminates above the head of a person, escape upwards, but when the motor is placed in a carriage the smell of the exhaust is noticeable, and although while the vehicle is travelling it may not be noticed for long periods, still in mounting inclines it becomes at times very unpleasant, and this will occur more particularly if the lubrication of the motor is not carefully attended to. The most serious objection to the carriages fitted with these motors is the great vibration which takes place while the carriage is at rest. If the carriage is fully loaded the movement is not so noticeable, as the bearing springs are of course compressed, but if it is empty the vibration is excessive. In case of a stop of a few minutes, it is always preferable to stop the motor altogether, and to use the hand lever for starting it. If the jets under the platinum tubes are left on there is no difficulty at all about this.

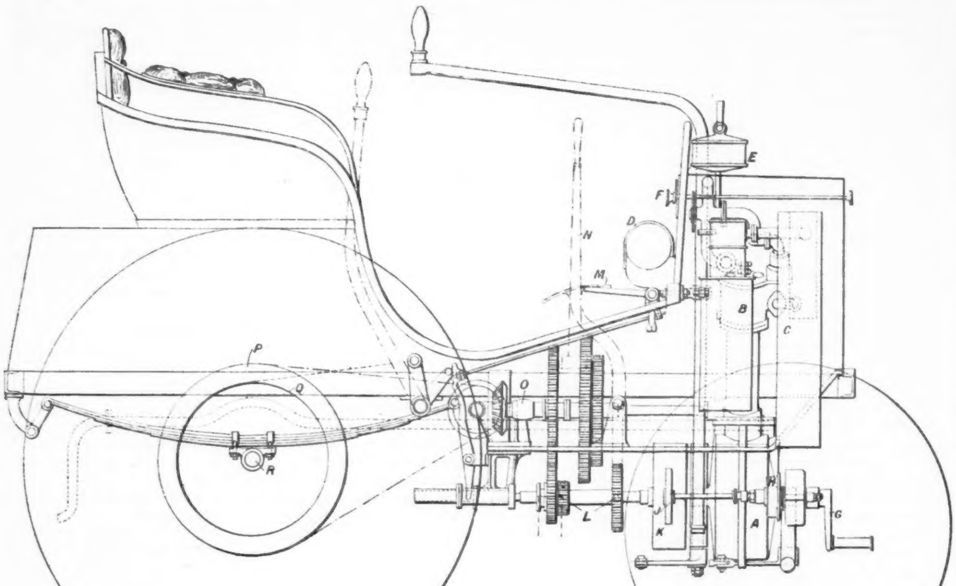

Fig. 1—MESSRS. PANHARD AND LEVASSOR'S CARRIAGE—GENERAL ARRANGEMENT

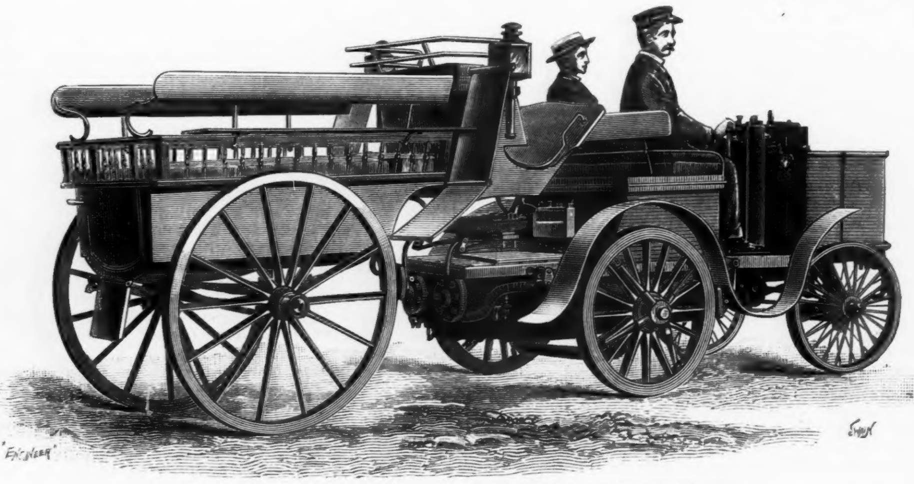

Fig. 4—DE DION, BOUTON AND CO.'S STEAM BOGIE CARRIAGE

The two cylinders are set so that their axes are both in the same vertical plane, and each axis makes an angle of about 15 deg., with a vertical line passing through the crank shaft. The motor is placed upright in the carriage, and the plane containing the axes of the cylinders is at right angles to the length of the carriage. The two trunk pistons drive on to one crank pin through connecting rods, and at full load there should be an explosion in each cylinder alternately; the result is that when the motor is running light and many explosions are missed, an excessive vibration is set up, owing to the fact that the pressures on the crank-pin cannot be balanced. I hope to illustrate the general arrangement of the motor and gear as applied to a carriage. The application of the motor to the carriage is practically the same by the two firms, Panhard et Levassor and Les Fils de Peugeot Frères, except that the former usually seem to prefer to place the motor in front of the vehicle, while the latter put it behind. In my opinion the rear position is decidedly the better, as the smell is more readily carried away from the passengers by the wind when the carriage is moving. But it is somewhat difficult with some types of carriage to obtain a proper balance of the parts, and this leads to slight differences in design. All the vehicles exhibited by Messrs. Peugeot had come along the roads a distance of 372 miles from Valentigney (Doubs) which is itself a proof of the practical utility of the Daimler motor, and also of the good construction of the vehicles.

By the kindness of Messrs. Panhard et Levassor, I am able to illustrate in Figs. 1 and 1A the general arrangement of the Daimler motor in a carriage; the particular vehicle happens to be for two persons only, but there are only slight changes in the application of the motor to other types. The motor A is entirely enclosed; the lower part is a cheese-shaped iron casing, from which branch the two cylinders. B is the carburator. C is the box into which the exhaust escapes, so as to deaden the noise. D is the gazoline reservoir. E is the vessel feeding the burners for heating the platinum tubes. F is the regulating cock. G is the handle for starting the engine. H is a centrifugal pump for the circulation of water. J is the pulley which drives the circulating pump. K is the special driving clutch, which forms the subject of a special patent. This is illustrated more clearly in Fig. 2. The shaft *c* carries one conical part *b*, covered with leather *a*, the part *b* is driven by *c*, but can slide on a feather, and is supported by spiral springs *d*. The other part *b'* is fixed on the shaft, and covered with leather *a'*. It will thus be seen that the surface *a* comes first into gear with the other half of the clutch, and afterwards the part *a'*. The wheels marked L are all made of gun-metal, and represent four different speeds at which the vehicle can be driven. Before altering the speed the pedal M is pressed down, and thus the gearing is brought to rest by means of the lever N; the speed is then altered. The upper shaft O drives through bevel wheels a chain wheel on each side of the vehicle, and this actuates the chain wheel P. The pulley Q is that upon which the brake acts so as not to damage the india-rubber tires. R is the axle which is provided with differential gear so that sharp curves can be turned. In Fig. 3 is given a sketch of the steering—*f f'* are the wheels, each wheel pivotted at *ee'* respectively; *b* is the steering lever moving the vertical shaft *a*, upon which is keyed the tee-shaped lever *c*; the joints *d d* are all Hooke's joints.

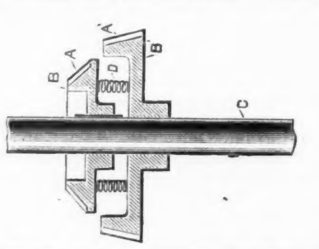

Fig. 2—PANHARD AND LEVASSOR'S FRICTION CLUTCH

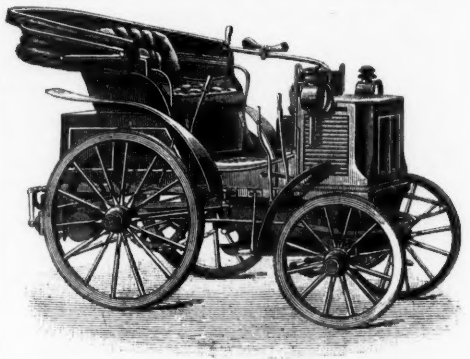

Fig. 1a—PANHARD AND LEVASSOR—TWO SEATS

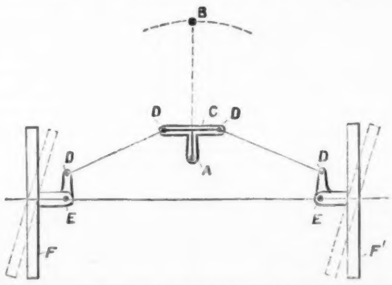

Fig. 3—PANHARD AND LEVASSOR'S STEERING GEAR

The speeds are usually regulated so that a maximum of 11 miles an hour can be obtained. With the lowest speed gear—3·5 miles per hour—it is stated that the carriages will ascend a gradient of 1 in 10 if the road is dry and in good condition. Ordinary gasoline, or essence of petroleum, is used with a specific gravity of 700 to 705. This can be bought almost anywhere in France. The main reservoir contains enough oil to run the carriage fifty miles, but there is a separate compartment in which a store may be kept so as to enable a journey of 186 miles to be accomplished without obtaining more oil. The water tank contains about 7½ gallons, which are used for circulation round the cylinders. This should be renewed every thirty miles. The tubular frame of the vehicle is used for this water supply. The cost of the gasoline is at present, in Paris, 12·8d. per gallon, petroleum being about 9d. per gallon.

The carriages to carry four persons are provided with motors of 3.5-horse power, and the consumption of such a motor with loaded carriage may be taken at 0·35 pint per mile, which is at the rate of about 0·56d. per mile. The consumption of gasoline is stated to be 1·14 pints per brake-horse power per hour. The total weight of the 3·5 brake-horse power motor and gearing is 440 lb., exclusive of oil, and the total weight of the carriage for two persons, as illustrated in Fig. 1A, in working order with motor, store of oil and water, is about 1300 lb., while a carriage for four persons, complete, will weigh from 1500 lb. to 1600 lb. The motor will run at speeds up to 800 revolutions per minute, and always in the same direction; but the carriage can be backed by changing the gearing. The two platinum tubes for causing the combustion cost 28s. each. The price of the carriage to seat two persons and fitted with hood is about £180, and to seat four persons, about £225. These are prices taken from the catalogue of Messrs. Panhard et Levassor.

The weather has been splendid, and at 7 a.m. on Thursday, the 19th inst., the competitors and spectators began to collect at the Porte Maillot, Neuilly, just outside Paris. The carriages which were to take part in the first day's trials arrived between this hour and 7.45 a.m., and they were arranged in single file at distances of about 50 yards apart. The whole of the course near the starting-point was lined with spectators, who were with difficulty kept in order by the police. Scores of bicyclists, both ladies and gentlemen, prepared to accompany the carriages. By reference to the map already published, the routes can easily be seen, and the following were the carriages which took part:—Route No. 1, Paris to Mantes, Nos. 3, 13, 21, 30. Route No. 2, Paris to Mantes, Nos. 10, 15, 28. Route No. 4, Paris to Rambouillet, Nos. 7, 18, 19, 42. Route No. 5, Paris to Corbeil, Nos. 4, 27, 29. Route No. 6, Paris to Précy-sur-Oise, Nos. 12, 14, 31.

By the invitation of M. Giffard, whose *nom-de-plume* is "Jean-sans-terre," I took a seat in carriage No. 4, that of Messieurs de Dion, Bouton and Co. The carriages were started at intervals of thirty seconds and I soon found that our progress was much more rapid than any of the others. The carriage is shown in Fig. 4, except that a Victoria was used instead of a wagonette, and it consists really of two parts, one a bogie with two axles and four wheels, which carries in the front a small vertical boiler, which is fed with coke from above into a central tube which communicates with the fire grate, and is closed above all round the boiler; the coke is stored in a chamber provided with hinged lids, the steam actuates a compound horizontal engine placed underneath the footboard of the bogie and partially behind the front seat; this will be seen from Fig. 4. The driving shaft passes through the hollow axle boxes of the wheels, and the latter are perfectly loose. Upon each end of the driving shaft is fixed a boss with four arms of wrought iron, and these drive against small stops securely fixed to the rim of the wheels. It will thus be seen that no stress is put upon the spokes of the wheels at all. A reservoir of water is provided also beneath the foot-board. All the controlling levers and brake are placed near the hand of a person sitting on the right side of the front seat. At the back of this bogie is a centre pin and cross springs suitable to accommodate the front lock of an ordinary carriage or coach, so that the same bogie is applicable to several carriages. The question might arise as to what is the proper definition of a self-moving carriage, and whether it is legitimate to include in this category a separate motor, but without stopping to define the exact requirements of a self-moving carriage, I will record the results.

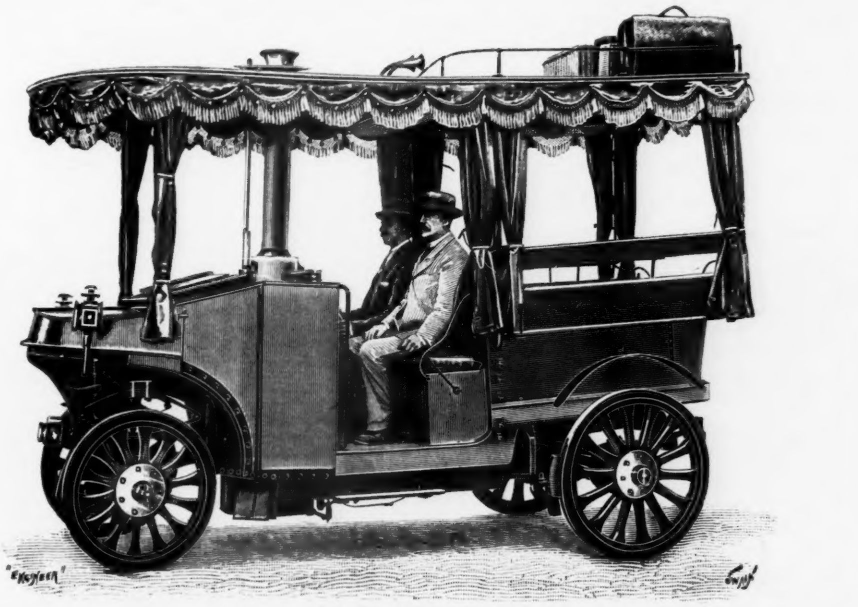

FIG. 6—SCOTTE'S STEAM CARRIAGE

We passed the Octroi of Suresnes at 8.35 a.m., and speedily overtook Nos. 7, 18, 19, and, in fact, we mounted the very severe inclines on this route without the least change of speed. The fore wheels of the bogie were covered with india-rubber about $\frac{5}{8}$in. thick, put on in separate pieces about 10in. long; while the back wheels were provided with the usual iron tires.

The steam pressure at starting was 163 lb. per square inch, and it never fell below about 140 lb. The weight of the bogie loaded is two tons, and this is said to be capable of drawing a load of 1·2 tons at a speed of 12·4 miles per hour up a gradient of 1 in 12·5. Sufficient coke is carried for a journey of sixty-two miles. and sufficient water for about twenty-five miles. It was stated that steam could be got up in fifteen minutes. The exhaust steam is carried away at the back by a tube under the bogie. This discharge is somewhat annoying to any persons coming immediately behind, and, of course, at starting there is always a considerable discharge of steam from the cylinder cocks. No chains are used for transmitting the power to the axles, as the driving shaft is connected to it by Hooke's joints. The engine is said to develope 20-horse power, and we travelled at a speed of twenty-one miles an hour very often. At Versailles we stopped ten minutes for water, and started again at 11·5 a m. At St. Geneviève des bois we made a second stop for water, and there saw a vehicle with a Daimler motor, which I was told had been used for three years by the commercial traveller to whom it belonged. This vehicle was taking no part in the competition, but it served to show that the petroleum carriage is a recognised conveyance in France. We reached the Place du Marché at Corbeil at 11.42 a.m., which, allowing for stops, made a journey of thirty-five miles in three hours. There were three persons in the carriage proper, which was a Victoria with the front wheels taken off, the Count de Dion and the driver were upon the seat of the bogie carriage. We arrived an hour before No. 27, and No. 29 reached Corbeil at 1.35 p.m., having been delayed by running into a bank at the side of the road; this caused it to be disqualified, as it arrived too late. The bogie of Messrs. de Dion et Bouton is very well suited for drawing goods wagons of moderate weight, but I fear that it is hardly suited for family use at all, as a skilled mechanic is absolutely essential. The distance of 35 miles was accomplished by No. 27, built by Messrs. Peugeot, in 4 hours 30 mins., including stops, this makes an average of at least eight miles per hour.

While waiting at Corbeil, before returning to Paris, I had, through the introduction of Mr. Lamy, of the *Petit Journal*, the opportunity of visiting the immense paper mills of Messrs. Darblay Père et Fils. These mills are said to be the largest in the world, and make wood-pulp paper only. The *Petit Journal* is supplied thence with its entire stock.

Looking now at the other routes; upon No. 1 all went well for about half a-mile, and then No. 21, a steam motor carriage belonging to Mr. Letar, broke down altogether. This carriage had a vertical boiler in the front, and the exhaust and steam was led away below; the engine was of the compound type, underneath the foot-board. Coke was used as fuel, and it was charged into the top of the boiler, as in the case of that of the Count de Dion. The top of the boiler was then closed by a tightly-fitting cover. The tires of the wheels were of solid india-rubber. The other vehicles went on to Ecquevilly without accident; but there No. 3, built by Messrs De Dion et Bouton, broke a connecting-rod; the engine was of the compound type, and similar to that of No. 4. The connecting-rod appears to have been of cast steel, and to have broken at a point where the metal was spongy.

On Route No 4, the steam motor No. 19, of Mr. Le Blant broke a slide-valve rod; but, after an hour's delay, this was put right in a temporary manner, and the carriage arrived at its destination.

On Route No. 6, the carriage No. 12, belonging to Mr. Tenting, broke down and could go no further.

The general result was, that out of seventeen starters thirteen remain in the list for the final, two steam engines and two petroleum motors having been disqualified.

On Friday, July 20th, only six carriages in all presented themselves at the Porte Maillot for the competition, although there were a number of private carriages of similar type there to see the start. The weather was magnificent, and but for the dust which rose in clouds all along the route, the journey would have been most enjoyable. The vehicles present were Nos. 44, 60, 61, 65, 64, 85, and in order to simplify the conditions, as there were so few competitors, it was decided to reduce the number of routes to two. Nos. 61 and 85 were sent off to Corbeil, and the rest to Mantes. There is very little for me to note here, as the whole of the vehicles arrived within the specified time, and were therefore all eligible for the final heat. Although it was at first decided that on Saturday no carriages should run at all, this rule was changed to allow seven vehicles to have a chance of competing, and the route was changed to enable the vehicles to get back to Paris early. Only two carriages presented themselves on Saturday morning, these being No. 24, Mr. Vacheron, petroleum motor, and No. 53, Mr. de Bourmont, also a petroleum motor. Both these ran over the course specified, and were admitted to the final test.

---

PARIS, Monday, 23rd July.

Sunday was a very busy day for all concerned in the competition, for the final heat was to be run. I feel that I am hardly justified in speaking of it as a heat, for the competition is in no sense a race, and no notice will be taken of speeds exceeding $7\frac{3}{4}$ miles per hour.

On Sunday morning, at 7 a.m., I presented myself at the Porte Maillot, and at 7.45 a.m. I found that the whole of the twenty-one vehicles still in the competition had arrived. "Jean-sans-terre" and his assistants very kindly set themselves to work again to find places for the engineers who were acting in a consultative capacity, and by 8 a.m. every one was seated. The trembling of the carriages fitted with petroleum motors ceased, and the procession proceeded between rows of people down the Avenue de Neuilly.

Several of the vehicles still in the list, Nos. 18, 19, and 44, were provided with Serpollet boilers, and Nos. 18 and 19 were both very heavy vehicles. No. 18 was entered by Mr. Archedeacon, of the Avenue Wagram, Paris, and was an omnibus bearing the description Société de Transport de la Guadeloupe, Service de la pointe-à-pitre au Moule, and No. 19 was a large parcel delivery van, built by Messrs. Chastel and David, and belonging to "La Belle Jardinière," a large general store; the latter had a steam engine of the Le Blant type, with three cylinders all working at the same pressure, and the whole car weighed $3\frac{1}{2}$ tons. The motor was stated to be able to develope 10-horse power; the width of the van was 7ft. $4\frac{1}{2}$in.; and the wheels were actuated by link chains of the Galle type. The Serpollet boiler was fed with briquette fuel, and the smoke produced was at times excessive.

At 8 a.m. I took my seat in No. 13, a carriage for four persons, two being seated looking forward, and the other two with their backs to the former. The vehicle was built by Messrs. Panhard et Levassor and Mr. Panhard, jun., was driving. In travelling along the road in a carriage going somewhat more rapidly than several of the others, I had a good opportunity of noting the movements of the springs and of the guiding apparatus. I shall give details in a future article of some of the methods of steering. That of Messrs. Peugeot appeared to work exceedingly well, and while allowing a very easy motion did not seem to be affected by the passage of the wheels over small stones. Both Messrs. Panhard et Levassor, and Messrs. Peugeot use a radial lever for steering, and it seems to act perfectly for these light carriages. No. 24, a petroleum motor belonging to Mr. Vacheron, was provided with a steering wheel instead of a lever, but this did not appear to me to be so satisfactory. The lead was taken throughout by No. 4, the carriage in which I went to Corbeil on Thursday last, and so far as could be seen all went well until we reached Nanterre at 8.40 a m., where we found that No. 44, belonging to Mr. de Prandiéres, had broken its driving axle close to the wheel, and was, therefore, useless. This particular portion of the road is very bad, consisting of uneven paving sets for some distance. After this we reached the incline of St. Germain, of 1 in 12, and the steepest on the whole route. This ascent was made slowly, but without accident. All the petroleum motors used the slowest gear of the four with which they are provided.

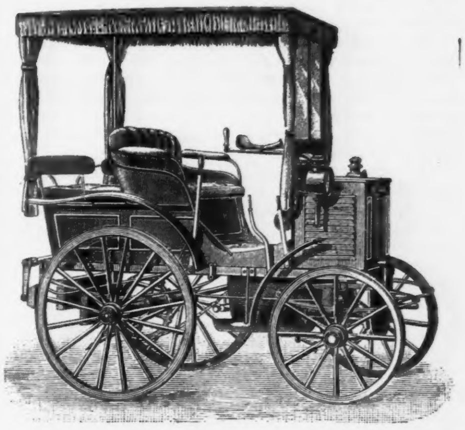

Fig. 5—PANHARD & LEVASSOR'S CARRIAGE-FOUR SEATS

At the end of the wood of St. Germain a stop was made to allow a change of places to be made.

No. 4 crossed Mantes Bridge at 11 o'clock. At 11·03 a.m. No. 65 arrived, belonging to Messrs. Peugeot, and after that No. 15 of Messrs. Panhard and Levassor, within ten minutes afterwards Nos. 28, 64, 30, 14, and 10 arrived. All but Nos. 4 and 10 being fitted with Daimler motors. Between 11.30 and 11.45, Nos. 13, 24, 27, 18, 53, and 42 arrived. At noon No. 60, at 12·05 No. 85, and at 12.15 No. 31. All within the time allowed—noon—except two. The vehicles were put up in the yards of several hotels, and luncheon was taken, and meanwhile No. 61 arrived at 12.30 p.m., No. 7 at 12 44, and No. 19 at 1.16 p.m.

Mantes was left at 1.30 p.m. by almost all the carriages, and the journey proceeded through a number of small villages to Vernon. Along the whole of the road from Paris groups of people were stationed, who offered bouquets and fruit to the persons in the vehicles; and it appeared that entire schools in many cases had been brought out to see the sight. An examination of the route will show how steep the hills are in many places. In most of the villages the principal streets are paved with large sets, which it is necessary to travel over at a moderate pace, but the rest of the road is macadam. Almost the entire distance was in splendid condition, and for miles as smooth as possible; this is accounted for by the fact that the "routes nationales" are under the direct charge of the State, and are looked after by engineers of the Department of the Ponts et Chaussées. At Mantes I had changed my carriage, and taken a seat in No. 64, Fig. 5, and we reached Vernon at 2.40 p.m., leaving again at 2.45 p.m.

Before reaching Pont de l'Arche we came to a piece of road which was under repair, the whole width was covered with flints which had not been rolled. The carriages had some difficulty in passing over this portion, and the result was that some of the india-rubber tires were badly cut. Our driver had brought rather too small a quantity of lubricating oil, and before we could buy more the motor was beginning to heat. As soon as this occurred of course a smell could be noticed, which was not observable at all while the lubrication had been good. The brake upon the driving wheels pressed direct upon the india-rubber in No. 64, and in other cases also. This, I think, is not a good arrangement with wheels of this class, and the separate disc brake with strap, used upon some other carriages built by Messrs. Peugeot appears preferable. India-rubber tires must be a somewhat heavy item in the repair bill, if work is done over the roughly-paved streets of country towns, or down the steep inclines with the brake on.

No. 4 mistook the route and mounted a very steep hill, and in turning to descend again, went into a potato field, and aid had to be obtained to get it on to the road again. For some distance before reaching the centre of Rouen, the route was decorated with flags, and after mounting an incline as steep as that at St. Germain, the carriages reached the Champ de Mars in the following order. The limit of time for arrival was specified as 8 p.m.:—

| No. | | |
|---|---|---|
| No. 4. | de Dion, 4 persons, steam ... ... ... ... | 5.40 p.m. |
| 65. | Peugeot, 4 persons, petroleum ... ... ... | 5.45 ,, |
| 28. | ,, 4 ,, ,, ... ... ... | 5 50 ,, |
| 13. | Panhard et Levassor, 4 persons, petroleum | 6.03 ,, |
| 31. | Peugeot, 5 persons, petroleum ... ... ... | 6.07 ,, |
| 42. | Le Brun, 4 persons, petroleum... ... ... | 6.24 ,, |
| 15. | Panhard et Levassor, 2 persons, petroleum | 6 30 ,, |
| 64. | ,, ,, 4 persons, petroleum | 6.49 ,, |
| 53. | de Bourmont, 4 persons, petroleum... ... | 7.01 ,, |
| 30. | Peugeot, 3 persons, petroleum... ... ... | 7.02 ,, |
| 24. | Vacheron, 2 persons, petroleum... ... ... | 7 03 ,, |
| 27. | Peugeot, 2 persons, petroleum ... ... .. | 7.05 ,, |
| 14. | Panhard et Levassor, 4 persons, petroleum | 7.10 ,, |
| 85. | Roger, 4 persons, petroleum ... ... ... | 8 09 ,, |
| 60. | Le Blant, 8 persons, steam... ... ... ... | 8 50 ,, |

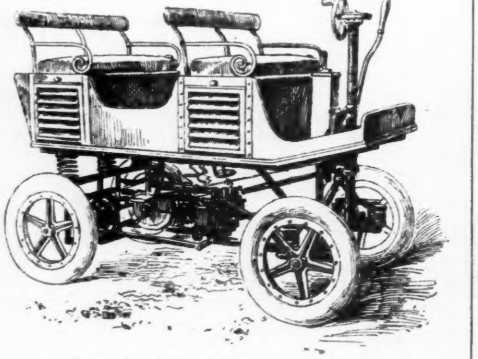
It is somewhat instructive to note that only one carriage out of the thirteen which arrived before 8 p.m. was driven by steam; all the others being petroleum motors, mostly of the Daimler type.

My own opinion is that steam is quite unsuitable for private persons who wish to drive their own carriages. The objections to the use of petroleum, or rather gazoline, are, first, the smell, which, when the motor is running properly, is almost absent; and, secondly, the vibration while at rest. I was anxious to see the electric motor which was entered, but it did not appear.

It was, of course, impossible to know what was happening upon the road, but I learnt this morning that a serious accident had happened to No. 10, the large steam carriage belonging to Mr. Scotte, of Epernay, Fig. 6. It appears that at Gaillon, which is marked upon the map, one of the "Field" tubes inside the vertical boiler burst, and there was an explosion which caused some injury to the vehicle and slightly injured the driver.

After the arrival of the bulk of the competitors, dinner was served at the Hotel de l'Angleterre, and "The continued prosperity of *Le Petit Journal*" was proposed by Captain de Place, who has been present throughout the trials. We described some time ago a special instrument resembling a telephone, invented by Captain de Place, who has taken much interest in the competition. The greatest surprise is expressed that so little has been done in England in the construction of self-moving vehicles suitable for private families. The roads in many parts of England are good, although certainly not so well kept as those I have just passed over. The authorities in the United Kingdom appear to do what they can to hinder the use of such carriages, whereas in France, which we usually consider as under bureaucratic rule, everything possible seems to be done to encourage their use. Should the use of these vehicles increase to the same extent as that of cycles, the business will be exceedingly important. The petroleum carriages can go as fast as any ordinary cyclist cares to travel, as can easily be seen from the times quoted.

The engraving below illustrates the carriage which has been referred to, as made for Messrs. Blumfield and Garrard, Coventry, by Messrs. Taylor, Cooper, and Bednell, Coventry. It carries four persons, and takes the form of a self-propelled mail phaeton, in which electricity is the motive force, and in which points which have proved valuable in cycle construction have been embodied. The *Cyclist* says:—"Messrs. Garrard and Blumfield's patent is for the combination of the known elements of (1) pneumatic tyres, (2) balance gear, (3) steel tubing, (4) ball bearings, and (5) electric power, and the machine in question has been devised to embody in the most practical form these several elements." The mechanism of the carriage and its framework are built throughout of weldless steel tube. There are four wheels, the two front being steered by means of a long ball socket head, actuated by a wheel and tangent screw. The wheels are the same size, *i.e.*, 24in., with 4in. pneumatic tires. The wheels and all working parts run upon ball bearings, and the current is obtained from twenty-four accumulator cells, in boxes arranged beneath the seats. These cells are connected with a motor carried upon the framework beneath; the motor spindle carries a roller on a feather, so that it can be moved to and fro several inches by means of a lever, placed in contiguity to the rider's left-hand. The roller runs between two discs. The discs are connected by toothed gearing and a chain with the balance gear which drives the two back wheels; the disc and roller driving gear being thus once more on its trial. The body of the carriage is placed upon the framework of the machine. The accumulators weigh some 500 lb., and the completed vehicle with accumulators about 1000 lb., or roughly speaking about half a-ton. The electric motor runs constantly at the same speed, the graduation of power or speed of propulsion being made by the shifting roller referred to. A powerful band brake acting on the balance gear is worked by a foot lever placed conveniently to the right foot of the "engineer." The machine is calculated to run at speeds varying from 3½ to 13½ miles per hour, according to the gradient over which it is running, or the wish of the occupants. It is stated to have run a trial trip to Birmingham, a distance of eighteen miles, at a speed of ten miles an hour over many parts of the road. One charging of the accumulators is calculated to be sufficient for a run of from seventy to eighty miles, and it is estimated that the cost of re-charging will not exceed 3s.; 2-horse power being the maximum discharge capacity required.



Garrard and Blumfield's Electric Carriage

The prizes were awarded last Monday, July 23, after a meeting of the whole of the twenty-five persons on the staff of *Le Petit Journal* who had formed the jury during the trials. The 1st prize, known as the "Prix du *Petit Journal*," and of the value of £200, is to be equally divided between Messrs. Panhard and Levassor, and Les Fils de Peugeot Frères. The carriages exhibited by both firms appeared equally good, both being fitted with Daimler gasoline motors. The second prize of £80, known as the "Prix Marinoni," was awarded to Messrs. De Dion Bouton et Cie. for their steam bogie, suitable for use with any class of vehicle. Although, as the jury remarked, this class of motor is not looked upon so favourably as those which can be placed upon the carriage itself, and which require no skilled attention. The 3rd prize of £60, Priz Marinoni, was awarded to Mr. Maurice le Blant, for his carriage to seat nine persons, and fitted with steam engine and Serpollet boiler. This type the jury consider specially adapted for heavy traffic such as omnibus work. The fourth prize of £40 was equally divided between Mr. Vacheron and Mr. Le Brun. Each of these gentlemen used the Daimler motor; but the jury consider that each has made important improvements in the methods of employing the motor. The fifth prize of £20 has been awarded to Mr. Roger for his improvements in the mechanism used with a petroleum motor. An additional consolation prize of £20 has been awarded to Mr. Scotte for his steam carriage No. 10, which was prevented from reaching Rouen by the bursting of one of the "Field" tubes. This could not be replaced on the Sunday.

## WEALTH STATISTICS.

FROM an interesting article under the above title in the last number of our able contemporary the *Statist* we extract the following schedule of fortunes left during the past seven years. In its commentary upon these figures the *Statist* holds that it would "probably be safe to say that such fortunes are not in the making in any of these great industries at the present moment."

### COALOWNERS AND MERCHANTS, IRONMASTERS, MACHINISTS, ENGINEERS AND CONTRACTORS.

| 1887. | £ |
|---|---|
| George Benton, of Benton and Woodewiss, contractor ... | 605,000 |

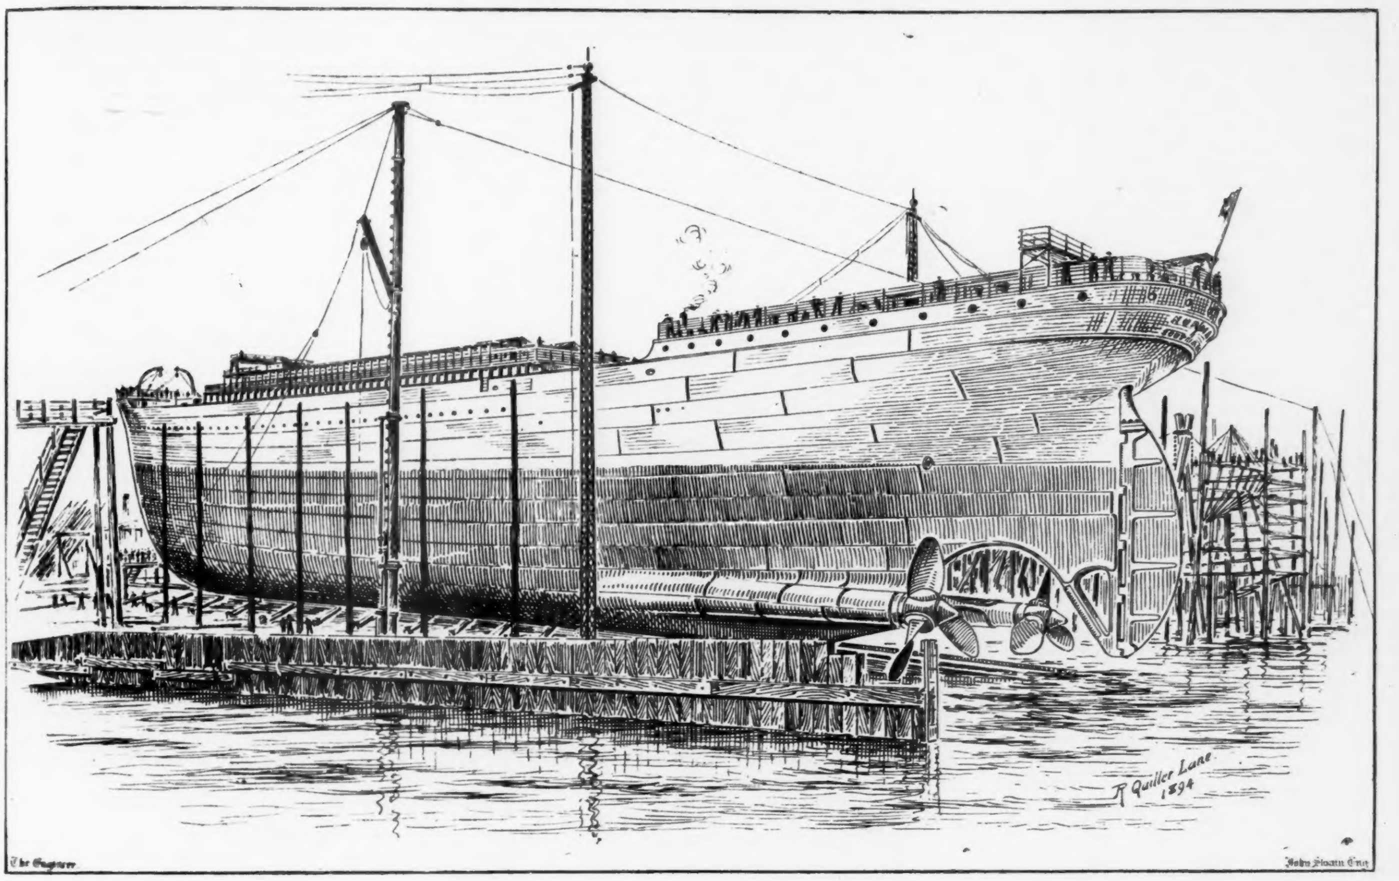
NAVAL ENGINEER APPOINTMENTS.—Engineers: E. J. Murphy, to the Renard; Wm. R. Parsons, to the Hasty; R. W. Parry, to the Edinburgh; John H. Jenkin, to the Gibraltar; James A. Roye, to the St. George; Walter Coleman, to the Magnificent. Assistant-engineers: W. E. Townsend, to the Theseus; E. J. Campbell, to the Barfleur; Thos. J. Dawson, to the Naiad; W. H. Page, to the Devastation; Charles Stevens, to the Northampton, to date July 16. Probationary Assistant-engineers: Charles G. Ware, to the Apollo; T. W. Richards, to the Sappho; H. R. S. Hughes, to the Tribune; A. E. J. Murray, to the Thetis; G. A. Sisley, to the Latona.

ELECTRIC RAILWAYS IN THE UNITED STATES.—According to the British Consul at Philadelphia, electric railways appear to be the method that is most generally adopted for locomotion through the streets of cities, and numerous franchises have been granted to such railways during last year. Some of the lines are working satisfactorily, and others are in course of construction, the trolley system of overhead wires being the one adopted. The franchises are granted in exchange for contracts concerning the paving of the streets through which the electric railways pass. In Philadelphia, and all over the country, the increase in electric railways has been enormous. Three years ago the mileage of horse tramcar roads was 5713; of electric roads, 1641; of steam roads, 554; and of cable roads, 527. Now electric roads exceed all others, with a total of over 7000 miles; horse-car roads have fallen below 5000 miles; cable roads have reached 1000 miles; and steam lines in cities have not materially increased. The cost of constructing a mile of cable road in a large city is put usually by engineers at £12,000. An electric road costs about £3600 per mile. The cost of working horse-car and steam street railways is about the same per mile. The cost of working cable and electric roads is about one-half of it. Electric roads are 10 per cent. cheaper to work than cable roads, and their cost of construction is 60 per cent. less.

THE NEW BRIDGES AT BUDAPEST.—In July, 1893, an international competition was announced for designs for two bridges over the Danube at Budapest. The first prize of 30,000 crowns was awarded to the design of the Esslingen-Stuttgart Machine Company, for the design of M. T. Ruebler, chief engineer of the company, and MM. Eisenlohr and Weigle, architects. Their design is for a wire suspension bridge with one span. The second prize of 20,000 crowns was given for the design of John Feketehazy, engineer at Budapest, for designs for a cantilever bridge with three spans. A third prize of 10,000 crowns was awarded for the design of the Reschitza Ironworks, with H. Schmuhl, architect, and Gregersen and Sons, contractors. The following designs were also bought for 5000 crowns each:—(1) The design of Brother Redlich and Berger, architects in Vienna, Francis Pfeiffer, chief engineer, Francis Podhsjaky, engineer, and Alexander Graf and Baron Krausz, architects. (2) The design presented by A. Rieppel, director of the Nürnberg machine manufactory, and Thiersch, architect. (3) The design presented by the machine manufactory of the Hungarian State Railways, Sfaléz Cathry and Son, engineers at Budapest. (4) The design presented by the Société de Construction de Levallois-Perret. The other designs are at the disposal of the competitors according to the notification in our advertising columns of this issue.

## THE NEW SOUTH AFRICAN MAIL STEAMER NORMAN

MESSRS. HARLAND AND WOLFF, BELFAST, BUILDERS AND ENGINEERS

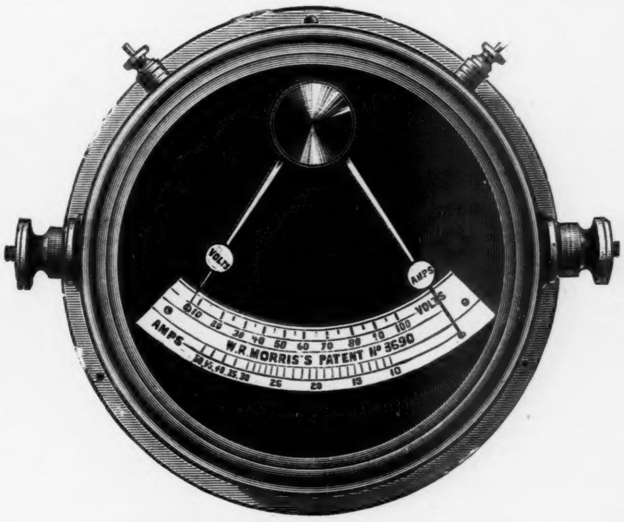


## THE NEW SOUTH AFRICAN STEAMER NORMAN.

On the 19th inst. the new twin-screw Royal Mail steamer Norman, which has been built for the Union Steamship Company's South African Mail Service, was successfully launched at Belfast by Messrs. Harland and Wolff. The ceremony of naming the Norman was performed by Lady Evans, wife of Sir Francis Evans, K.C.M.G., M.P., deputy chairman of the Union Steamship Company. The measurement of the Norman will be about 490ft. long (between perpendiculars); breadth, moulded, 53ft.; depth, 37ft. 6in.; and her gross tonnage will be about 7,500. She is constructed of steel, and fitted with twin screws like five others of the Union Company's fleet. The Norman will be fitted with two sets of triple expansion engines, and is designed for carrying a large cargo or considerable numbers of troops. Large numbers of passengers will be provided for in each class. The first and second class accommodation will be amidships, thus ensuring comfort, quiet, and ample ventilation, the third class being located on the main deck forward, and in this connection it may be mentioned that the Norman will be capable of berthing 160 third-class passengers on the main deck forward, with the saloon between them. The first-class saloon will provide seating accommodation for 250 passengers, and is to be situated on the upper deck. It will be beautifully decorated. The second-class saloon will be situated on the main deck aft, and will furnish seating accommodation for 100 persons. As regards the smoking rooms both for first and second-class passengers, nothing has been spared to make them as up-to-date as possible, and luxurious in the extreme. The former will be situated on the promenade deck amidships, between the funnels, and will be in dark Spanish mahogany, the walls being richly decorated in embossed leather, and the floor covered with Sir Edward Harland's patent india-rubber tiles. The ceilings of this room and the library adjoining will be artistically decorated, and both rooms will be 10ft. 3in. high. The Norman will be constructed with poop and forecastle, and will have central deck houses containing dining saloons, &c., over which will be an exceptionally fine promenade deck. Electric light will be installed throughout, and there will also be refrigerating engines and machinery, and cold chambers for ship's stores, as well as for the conveyance of fruit and other perishable goods. There will be nine watertight bulkheads, and the ship will be provided with water ballast and with all the most recent appliances and fittings. She will be provided with boats in excess of the Board of Trade requirements, and altogether the Norman will be a vessel of which the Union Company and the builders will have reason for being proud. The steamer leaves Southampton on her first voyage on the 10th November, 1894, and will leave Cape Town homewards on the 19th December.

## A COMBINED AMMETER AND VOLTMETER.

THE instrument we here illustrate is a very useful and compact meter. It consists of a strong brass case, 8in. in diameter, with four terminals; the two small terminals are used for the volts, and the two large terminals for the ampères. It has two hands or pointers; on each pointer is a disc, with the word volts on one disc and ampères on the other. By this plan there can be no mistake in the readings, and it will be noticed in the illustration that the disc on one pointer is fixed higher than the disc on the other. This arrangement allows both discs always to be seen, as one disc cannot come in front of the other and eclipse it. Another feature is a double scale. The top part is used for the volts, reading from left to right, and the bottom part for ampères, reading from right to left. It is not very easy to look at two instruments at the same time, even though they be placed side by side, but in this instrument we see at a glance what is going on, and by mentally multiplying the reading of one pointer by the reading of the other, we at once get the number of watts being used. This makes it also a wattmeter. As each pointer is separate and distinct from the other, it can be used separately as an ammeter or a voltmeter, as the ampère and volt circuits are entirely insulated from one another. No printed dials are used. Each scale is of large size, and is marked by hand during calibration, and afterwards engraved. This method prevents any errors caused by the use of printed scales or dials, and is a point of importance. The principle of the instrument is the action of a solenoid on a suspended piece of iron wire—which weighs only a few grains—and, as there are no permanent or electro-magnets or springs used in them, it is not expected that they will ever require recalibrating. The instrument is a gravity one and direct reading, and can always be left in circuit.



MORRIS'S COMBINED AMMETER AND VOLTMETER

To use the instrument it is screwed up vertically, so that the hands point to zero. The two top terminals are connected across the mains, and the two large terminals are connected in the circuit. The instrument is made by the inventor, Mr. W. R. Morris, 34, Livery-street, Birmingham.

## THE CARDIFF ELECTRIC LIGHT WORKS.

CARDIFF is to be lighted by electricity next month, for the first time from the station of its own Municipal Corporation, which supersedes, after an interval of time, the brave but brief enterprise of a private company. For more years than need be now recounted, the Council had been negotiating with the local gas company for the acquisition of its property. The borough had secured the control of the water supply by purchase from its private owners, and had exhibited its public spirit by tapping new sources in the Breconshire hills from thirty to forty miles away. It wanted to municipalise the gas supply, but the chartered monopolists seem to have regarded themselves as in a position to demand their own price. Four years ago the Corporation offered their ultimatum to the gas authority. As that was not accepted, they took the necessary steps to provide the town with its own works for the supply of electric illumination and power. The merest abstract of the history of the installation will be sufficient to instruct other municipalities in a similar plight, and other borough engineers placed in the like circumstances. An experienced electrician was sought out as adviser, the result being that Mr. W. H. Massey, M. Inst. C.E., was appointed consulting engineer. A committee was nominated, and it made an agreeable and instructive peregrination—quoting the words of the report—to London, Deptford, Bath, Havre, Paris, Brussels, Antwerp, Cologne, and Frankfort, "with the object of obtaining the latest available information as to the progress of electric lighting and the application of electricity to general industrial purposes." On a supplementary exploration the sub-committee visited Manchester, Bradford, and Leeds, not to omit the Electrical Exhibition at the Crystal Palace. Committees of this kind are the more omnivorous in their appetite for facts in proportion as their quest runs in pleasant places. The Cardiff sub-committee during 1891 and up to May, 1892, gathered, besides a great many delightful experiences, a mass of important details as to the newest forms of electric installation, which guided the Corporation to a decision. One or two passages from the report of the Committee to the Council may be usefully quoted:—"The conclusions that your sub-committee have so far arrived at are, that the promise of advantage to the community at large, to be derived from the development and application of electricity in the future, is such that a prudent municipality will not allow the control of what must practically be a monopoly to pass into the hands of any private individual or company established for the purpose of profit. This is altogether apart from the still graver consideration of allowing any other body than the Corporation to come into the borough armed with parliamentary powers to tear up the streets and pavements of the Corporation." Then, on the point as to the distinction between public and domestic illumination:—"The members of the Corporation are doubtless aware of the difference between incandescent and arc lighting. The one—incandescent or glow lamp—is generally utilised for domestic purposes, and the other—the arc light—for street lighting and the illumination of large areas, such as railway stations, manufactories and workshops; and different electrical processes are generally used for each of these methods of lighting, what is called the low-tension current being employed for domestic purposes, and high-tension for arc lighting, or for primary transmission. Without going into any technical details, it may be broadly stated that, for economical reasons, high-tension currents are necessary when it is required to distribute electricity to long distances or over large areas. It has already been demonstrated that this high-tension current can be transformed into low-tension, and thus made available for incandescent lighting by a very simple appliance; and your sub-committee are hopeful, from what they saw at Frankfort, and from what they gathered in conversation with electrical engineers abroad, that this transformation can be accomplished in an economical manner. In that case it is obvious that the most practical method of lighting a scattered district like the borough of Cardiff would be by concentrating the machinery in one spot, and distributing the electrical energy at a sufficiently high pressure over the given area, such currents to be transformed as and where required. The objection to high-tension currents consists principally in the danger to life and property which unprotected cables having such currents are likely to cause. By a proper system of installation, and laying the cables underground, however, this can be entirely obviated; but the higher the tension the greater is the cost of insulating and providing safety appliances, and that is one reason why your sub-committee call special attention to the moderate pressures likely to be required for distribution in Cardiff." In a subsequent report the sub-committee point out that "in laying down the requisite plant in the first instance, it is quite easy to so arrange it that by making additions to the building and the machinery, the whole may be formed into a generating station suitable for the supply of electrical currents for both light and power throughout the entire borough, and by this means establishment charges—expenses for staff and maintenance—would be reduced to a minimum." On another point of interest to the electrical engineer, which has particular reference also to the local opportunities of Cardiff, the sub-committee further remark:—"The utilisation of water power in connection with the new Taff Vawr (the Breconshire) water mains, and the adaptation of refuse destructors, by passing the waste heat and gases through boiler furnaces for the purpose of raising steam to drive electric light machinery, are schemes which may all be realised to some extent in the not distant future, and yet they do not in any way modify the present needs." Through these passages of the reports the guiding hand of Mr. Massey is, or ought to be, distinctly traceable, and it is upon the plans thus outlined that the Corporation installation in Cardiff has been made.

The site of the works is a piece of Corporation land on Canton Common, about a mile from the centre of the borough, and connected by a private siding with the Great Western Railway. Here there is a plentiful supply of good water, pumped from 10ft. below the surface, and this, if necessary, can be supplemented to any extent from the Corporation mains. The station to be made use of next month is one-fourth of its ultimate size, the idea being to extend it gradually as the demand for light and power increases. The buildings at present cover 80ft. by 80ft., and comprise an engine-room 80ft. by 30ft. on the street front; a boiler house of similar dimensions; together with a coal shed, 14ft. wide, facing the railway siding, and covered by a water storage tank running the whole length of the structure. The chimney stack is octagon in form, 150ft. high, 64 square feet in internal section, and capable of taking the draught of ten boilers, of which, so far, three are laid down. These are of the Davey-Paxman pattern, as also are the engines. The engines now in place are two compound 65-horse power direct, coupled to Siemens' 40-kilowatt alternators, and two triple-expansion 300-horse power direct, coupled to Siemens' 180-kilowatt alternators, the small to run to a speed of 200 revolutions, and the large to 133 revolutions per minute, all having their own exciters directly coupled on the same shaft, and delivering a current, at a pressure of 2500 volts, to concentric mains running to the centre of the compulsory area of supply, a mile away. It may here be noted that the compulsory area includes a small portion—little more than a fourth—of the widespread and rapidly growing town. It practically embraces no more than the streets occupied by the chief hotels, banks, and offices, and places of business. It leaves outside the pale the leading residential districts and almost all the working class suburbs. The idea of the municipal committee is, perhaps too timidly, to give the experiment a fair trial first of all in the zone where the demand is likely to be greatest. There are already many signs that as soon as the heart of the town is lighted in September, an immediate extension of the mains to places further afield will be required. For example, the authorities of Aberdare Hall—the house of residence of women students in the University College—are even now asking to be supplied with the light, and it is confidently predicted by persons who have had experience of electric lighting in other towns that the Corporation will not long be allowed to confine itself to the compulsory area; and under these circumstances the question is being raised whether the Municipality would not be wiser to enlarge its lines at once on a uniform plan rather than meet contingent applications by a series of patchwork processes.

The mains from the Canton station, though they run through a populous region and skirt the walls of Cardiff Castle, Lord Bute's occasional home, are untapped until they enter the chief thoroughfares of the borough. Then they communicate with six Siemens' transforming stations, placed without any particular regularity of interval, and where consumption is expected to be greatest. The transformers are connected in parallel, and feed the low-tension network at a pressure of 100 volts for the supply of hotels, offices, shops, or private houses. The mains also supply current to Ferranti rectifiers for the distinct arc lights of the public lamps. The rectifiers consist of a small self-starting synchronous alternating motor, with a commutator at each end of the shaft for changing the alternating into a direct current, and rectifying the two currents. Every direct current machine, as is well known, is an alternator and rectifier combined. Recent experience has shown that there is no difficulty in separating the two portions by a reasonable distance, with the advantage that the plant at the station is of one pattern; that this necessity of keeping spare plant in stock is reduced to a minimum; that separate mains for arc lighting are dispensed with; and still there is obtained the continuous current, so much preferable for arc lighting, owing to the action of the crater in the positive, or upper carbon, as a natural reflector, throwing the greater mass of the light on the street below. Each transformer station is connected to a separate low-tension network of wires in its own immediate district, and all of these independent centres are easily capable of being connected one to the other at will. The pipes and surface-boxes in which the cables run are of cast iron metallically jointed together, so as to provide for an efficient earth connection in case of a fault appearing; and thus all danger is precluded of such an accident as was some months ago reported from Bournemouth, and has, though in less serious form, occurred in other places where such safeguards were not provided. The street illumination is supplied by Siemens' "band" arc lights, arranged as a beginning in four series of twelve lamps each, the current being taken alternately from different circuits, so as to permit of every second lamp being extinguished at midnight when desired. The lamps stand 22ft. high, and are placed for the most part on the edge of the footway, though in a few instances they are in the middle of the road. For the rest, it describes them sufficiently to say that they are of the same pattern as those erected in the City of London, with reference to which the Cardiff Committee say in one of the reports:—"The best example of electric street lighting we have seen in England is that carried out by the Brush Company in Queen Victoria-street, where the arc lamps are placed at an average distance of forty-five yards apart." All the cables, it may be added, are from the Silvertown works. As to the question of cost, it is safer to deal with the estimates than the actual outlay, which cannot yet be reckoned up. The original figures were: for the mains, £8000; the transformers, underground chambers, &c., £2000; arc lights, lamp-posts, &c., £3000; buildings and chimney stack at Canton Common, £5600; boilers, £2500; engine steam pipes, condensers, £3500; an item set down as accessories, £5000; site credited at £1500; railway siding and turntables, £400; contingencies, £1000.

The works have been executed entirely by the Cardiff Corporation, under the direction of the borough engineer, Mr. W. Harpur, C.E.; but the credit, and in some sense the responsibility, of the installation rests mainly with Mr. W. H. Massey, M. Inst. C.E., of Queen Anne's Gate and Twyford, who has been retained from the first as consulting engineer. Mr. Massey has been most efficiently represented in Cardiff, throughout the progress of the work, by Mr. R. H. Fletcher.

## AMERICAN ENGINEERING NEWS.

(*From our own Correspondent.*)

*Railway operating statistics.*—The latest report from which I have been able to take details of actual operating expenses of railway operation is that of the Chicago, Rock Island, and Pacific Railway for the year ending March 31st, 1894. This road operates 3571 miles of railway, or 4472 miles of single track, including second and third track and sidings.

| | |
|---|---|
| Gross earnings—dols. | 21,039,073 |
| Operating expenses—dols. | 14,137,267 |
| Net earnings—dols. | 6,061,594 |
| Percentage of operating expenses to gross earnings | 67·20 |
| Passengers carried | 5,768,441 |
| Passengers carried one mile | 329,360,986 |
| Average journey per passenger—miles | 57 |
| Average rate per passenger per mile—cents | 1·9 |
| Earnings from sleeping cars—dols. | 92,902 |
| Earnings from dining cars—dols. | 114.879 |
| Total passenger earnings—dols. | 6,538,568 |
| Average receipts per passenger—dols. | 1·13 |
| Freight carried—tons | 7,056,569 |
| Freight carried one mile—tons | 1,288,576,685 |
| Average rate per ton per mile—cents | 1 |
| Number of loaded cars | 556,061 |
| Average load per car—tons | 13 |
| Total freight earnings—dols. | 12,852,978 |
| Number of men employed | 12 117 |
| Payments to employés per month—dols. | 659,443 |
| Passenger train mileage | 6,601,512 |
| Freight train mileage | 10,898,552 |
| Total train mileage | 22,174.795 |
| Earnings per freight train mile—dols. | 1·18 |
| Earnings per passenger train mile—dols. | 1·11 |
| Expenses per mile run—dols. | 0·68 |
| Cost of maintenance of track and bridges per mile run—dols. | 0·13 |
| Number of passengers carried one mile for each mile run by passenger trains | 50 |
| Average mileage per engine | 39,317 |
| Locomotives, cost of repairs per mile run—cents | 3·28 |
| Locomotives, cost of fuel " " | 6·41 |
| Locomotives, cost of oil and waste " " | 0·26 |
| Locomotives, cost of engineman, fireman, and wipers per mile run—cents | 6·58 |
| Locomotives, miles run per ton of coal | 29·64 |
| Number of cars per passenger train | 5·27 |
| Number of cars per freight train | 17·90 |
| Number of locomotives | 564 |
| Number of cars, passenger service | 462 |
| Number of cars, freight service | 15,840 |
| Gravel, hand, and work cars | 1,517 |

*Relining tunnels.*—On the Louisville, Evansville, and St. Louis Railroad the old timber lining and dry packing of some of the tunnels is to be removed, and the tunnels lined with brick. The ballast will also be removed, and the rails carried on wooden stringers, 12in. by 12in., while the invert is being built. The centreing ribs will be composed of four thicknesses of 2in. planks, with the extrodes trimmed to the arch radius. Upon these will be 2in. by 4in. lagging, breaking joints on the ribs. The lining will be of smooth, hard burned "paving" brick, of 4000 lb. per square inch crushing strength, laid in cement mortar composed of one part cement and two parts sand, with a tensile strength of 100 lb. per square inch seven days after mixing. The bricks will be thoroughly wet before laying, and all spaces will be filled in with mortar or grouted. In the side walls the bricks will be laid in English bond, with five stretcher courses to one header course, but there will be no headers in the arch rings. Where dry rubble masonry is built, as at the portals, &c., one fourth of the stones must be headers the full thickness of the wall. The packing will be of concrete composed of four parts of stone, two of sand, and one of hydraulic cement, mixed with water and rammed in layers. Weeper holes will be left in the tunnel walls, connecting with stoneware drain tiles laid in the concrete backing. The portals will be of first-class masonry, with brick or stone parapets and wing walls. The work must be carried on without interfering with the traffic, the track being cleared ten minutes before any train is due.

*Steel fire-boxes.*—There is considerable difference of opinion as to the best grade of steel for use in fire-boxes, as shown in the recent report at the convention of railway locomotive superintendents. Some prefer a soft steel of 50,000 lb. to 58,000 lb. ultimate strength, while others prefer a harder steel of 55,000 lb. to 65,000 lb. From the records of several hundreds of worn-out fire-boxes it was found that the tensile strength varied from 77,000 lb. to a little over 50,000 lb., while the mileages varied from 500,000 to a little over 50,000 miles. The results of the examination were quite conflicting, as was to be expected, considering that the use of the fire-box on the road had more to do with its life than the original quality of the metal of which it was constructed. It was found, however, that hard and soft steel might be found in both long and short-lived fire-boxes. The weight of evidence was, however, toward steel having a tensile strength of 60,000 lb., as giving the best results. There is a prejudice against hard steel as being more liable to crack, but improved methods of manufacture—such as machine flanging—and more careful methods of washing out boilers, are found to be removing many of the difficulties formerly encountered, and, after it has once been flanged, steel of 60,000 lb. tensile strength will give better results than that of 50,000 to 55,000 lb., while the harder steel holds the screw threads better and is less liable to bag between the stay bolts. The specifications recommended were as follows:—Fire-box steel is to have a tensile strength of 55,000 lb. to 65,000 lb., with 60,000 lb. desired, and an elongation of 28 per cent. in 8in. preferred. The chemical composition desired is: Carbon, 0·18 per cent.; phosphorus, not above 0·03 per cent.; manganese, not above 0·4 per cent.; sulphur, not above 0·02 per cent.; silicon, not above 0·02 per cent. Plates will be rejected having a tensile strength less than 55,000 lb., or over 65,000 lb.; an elongation less than 22 per cent. in 8in., and in ¼in. plates less than 20 per cent.; a failure to stand bending and quenching test as given for shell steel; any seam or cavity more than a ¼in. long in any of the fracture or homogeneity tests. Plates shall also be rejected having carbon over 0·25 per cent., or below 0·15 per cent.; phosphorus over 0·035 per cent.; manganese over 0·45 per cent.; silicon over 0·03 per cent., or sulphur over 0·045 per cent. The homogeneity test shall be made in the following manner: A portion of the broken test piece shall be nicked with a chisel on opposite sides alternately, the nicks being about 1in. apart, and the piece broken by a number of light blows, the bending being away from the nicks. If the laminations are more than ¼in. long, the piece shall be condemned. The object of this is to open and reveal seams, due to failure to weld up, or to foreign interposed matter, or cavities due to bubbles in the ingots. Shell plate steel is to have a tensile strength of from 55,000 to 65,000 lb., and an elongation of not less than 20 per cent. in 8in. Test pieces having rough edges removed by filing, grinding, or machining, shall, without annealing, bend over itself both while cold and at a cherry red heat and dipped in water at 80 deg. Fah. without showing cracks and flaws in the outside edge. There shall be no chemical requirements.

## THE IRON, COAL, AND GENERAL TRADES OF BIRMINGHAM, WOLVERHAMPTON, AND OTHER DISTRICTS.

(*From our own Correspondent.*)

In connection with the important engineering question mentioned in my letter of a fortnight ago, regarding the possibility of Staffordshire becoming a producer of steel girders of H section for warehouse and other similar building purposes, interesting information is forthcoming in the announcement that steel girders are already rolled in this district in the ordinary bar mills, and that the Staffordshire Steel and Ingot Iron Company is producing girders up to 7in. by 4in. If there were sufficient demand, the Staffordshire works would be ready to put down machinery for the rolling of larger sizes, but, as I before pointed out, this is a very expensive matter, and it is estimated that the requisite rolls necessary to engage in all departments of the trade would cost fully £20,000, and probably £25,000 or £30,000. A good girder mill will turn out from 100 to 150 tons of girders per shift, according to sizes on order, or 50,000 to 75,000 tons per annum. It is understood here that the mills of Messrs. Dorman, Long and Co., of Middlesbrough, would do this, and that the firm have in stock about 10,000 tons of steel girders in England, besides large stocks abroad. A great portion of the trade is export. As regards iron girders, up to the present no English firm can compete with the Belgians in price, but in steel the English makers fairly command the whole market.

Steel makers report more business doing on account of the Scotch strike, and the inability of the Scotch steel masters to execute orders. One leading local concern has just taken a big line of steel sheets for gasometer construction, and the way in which steel is increasing in favour among constructive engineers as a gasometer material, is a very gratifying experience of the steel makers at the present time.

Last week I announced that the Great Western Railway Company was intending to erect at Wolverhampton new works for the manufacture of oil gas for the lighting of railway carriages. I am now in a position to state that not only is this so, but that the company is also intending to enlarge its engine-building works at Wolverhampton. It has just purchased about seven acres of land adjoining the present works, with the object of putting down additional boiler-making and fitting shops, as the present plant is unequal to the strain in output put upon it. The wages paid at this large works now amount to about £2500 per week, and the new extension will mean the employment of a considerable number of additional hands.

It has this week been intimated that the notice which has already been served—as previously mentioned—upon the men of the Corngreaves Ironworks, of the New British Iron Company, Cradley Heath, and which was to expire on the 31st inst., will have to take effect, as all efforts to sell the works have been unavailing. Messrs. Barnett and Son, of Wolverhampton, the auctioneers, will therefore be instructed to prepare forthwith for the dismantling of the works, and for the disposal of the various portions of the estate by means of a forced sale. The works were founded in 1825, and are now among the largest and best equipped in the kingdom. In the prosperous years, between 1873 and 1880, when trade was good, and best Staffordshire iron was in great demand, a golden harvest was reaped, but this has been more than discounted by the depression of trade since then. At present there are about 1700 workpeople employed under the company, who receive something like £1500 to £2000 in wages weekly. The aggregate freehold surface area is about 230 acres, with a mineral area of 530 acres. Some years ago a steel making branch was added and fitted up with the most modern appliances, and as time went on a chain factory, a brick works, and other departments were entered into. Six collieries have also been acquired.

All interested in the progress of coal mining in South Staffordshire are expressing satisfaction at the fact that the South Staffordshire Mines Drainage Bill, which has already passed through the House of Lords, has now also passed its committee stage, and will in due course be reported for its third reading. By the Act of 1891 the Commissioners were authorised to raise a money loan of £100,000 for pumping operations to clear South Staffordshire mines from water. They have already expended a large sum of money for that purpose, and the whole of that expenditure is likely to become useless unless the works can be kept going and the water in the mines actually overcome. The Commissioners have previously obtained powers to create a new charge of £100,000, but on application to the Public Works Loan Commissioners and others to lend this money, it was considered that the security under the Act was not sufficient. Therefore, after a great deal of negotiation between the parties concerned, the term of the Bill has been agreed to, the effect of it being to make certain mines up to a certain figure collateral security for the money advanced.

## NOTES FROM LANCASHIRE.

(*From our own Correspondent.*)

*Manchester.*—The wages settlement in the coal trade has necessarily been a matter of considerable discussion during the past week. So far as the colliery owners are concerned, it can scarcely be said that the agreement come to by the Conciliation Board has given general satisfaction, and although practically it has been ratified by the Federated Coalowners, not a few of them are very dubious as to the wisdom of the step that is being taken, whilst outside the Coalowners' Federation, and even on the part of one or two of its prominent members, there is a strongly expressed opposition to being bound to the proposed fixed rate of wages over the next couple of years, and it is not improbable that some of the collieries in the district may decline to commit themselves to the Conciliation Board agreement. The question has consequently arisen whether the Miners' Federation will take any action with regard to the collieries that decline to be bound by the agreement to the extent of not allowing the miners in such cases to work at the 10 per cent. reduction, until such collieries signify their assent to be bound to the agreement. Upon this point I do not hear of any really definite arrangement having been come to; but it is not improbable the official leaders of [illegible] Miners' Federation may co-operate with the Federated C[illegible]wners to secure a general acceptance of the terms of agreement—and there would almost seem to be some sort of tacit understanding that those collieries which have hitherto been the cause of the underselling in the market, shall be dealt with one way or another, so that a check may be given to the excessively-low cutting in prices. On the part of the miners in Lancashire there is also no very general satisfaction with regard to the agreement, so far as it carries out a reduction in wages; but there seems to be very little doubt that—on the advice of their official leaders—they will, like the Federated Coalowners, give their assent to the proposed terms of settlement.

Business in the Manchester Iron Market drags on in a lifeless hand-to-mouth fashion, and the continued absence of any indication of improvement is inducing rather a despondent tone as to the future. In pig iron buying is restricted to the smallest possible quantities, and for local and district brands prices continue low and weak. Lancashire makers, to meet the competition of Lincolnshire iron, have to give way considerably upon the nominal quoted rates, and with regard to forge qualities these would seem to be more a matter of offers than of any actually fixed price; 39s. to 39s. 6d., less 2½, at the works, is what local makers have been quoting, but considerably under these figures would have to be taken to secure business. For foundry qualities, occasional sales to special customers are made at something like their quoted rates, but 41s., less 2½, represents more nearly the figure which has to be taken. Lincolnshire brands are now being quoted at 38s. for forge to 39s. for foundry, net cash, delivered Manchester, and 3d. under these low figures would, in some cases, be accepted to secure orders. Derbyshire foundry varies considerably according to quality, ranging from about 43s. 6d. up to 45s. and 45s. 6d., net cash, delivered Manchester. The continuance of the miners' strike of Scotland is necessarily tending to keep up a firm tone for outside brands offering here, but except that in one or two cases Scotch makers have put up their quotations for special brands, late prices are not much more than maintained, and certainly business is extremely difficult at any higher prices. For good foundry Middlesbrough prices still average 43s. 10d. to 44s. 4d., net cash, delivered Manchester. There is so little Scotch iron offering, that prices can scarcely have much value, but it may be stated that Eglinton is quoted at 46s. 6d. to 46s. 9d.; Glengarnock, 49s. 6d., and Gartsherrie, about 50s. to 50s. 6d., net prompt cash, delivered at the Lancashire ports.

The manufactured iron trade remains generally in a very depressed condition, makers still reporting no weight of new business coming forward, and it is difficult to keep works going more than three to four days per week. Quotations for Lancashire bars remain at £5 7s. 6d., and for Staffordshire £5 10s., delivered here, but in special cases something under these figures would be accepted. Lancashire sheets are still quoted about £6 17s. 6d. to £7 2s. 6d., Staffordshire about £7 5s.; Lancashire hoops, £5 17s. 6d. for random, and £6 2s. 6d. for special cut lengths, delivered Manchester or Liverpool.

Nut and bolt makers report trade as becoming, if anything, more and more unsatisfactory. Very few orders are to be got, and these are competed for at continually receding prices.

In the steel trade only a very limited weight of business is being put through, and prices are somewhat irregular. For ordinary foundry hematites, 52s. 6d., less 2½, delivered Manchester, remains about the average quoted figure; ordinary basic billets do not average more than £4 net cash, delivered here, and could be bought at under this figure, in some cases, while Bessemer acid billets are reported to have been offering at as low as £4 net cash, delivered. In steel boiler plates, quotations vary, ranging, according to circumstances, from £6 7s. 6d. to £6 10s., and £6 12s. 6d. per ton, delivered in this district.

The outlook in the engineering trades remains much as reported for some time past. Only in exceptional cases are establishments at all busy, and this mainly upon work of a special character. The general run of engineering continues for the most part very quiet, and new work comes forward but slowly—with the result that very few engineering establishments are kept more than moderately going from hand to mouth; and there is still no indication of any revival of activity, at any rate in the immediate future.

In the coal trade business during the past week has been to a very large extent practically in abeyance, owing to buyers holding back in the expectation that with the reduction of wages, which comes into operation next month, there will be some corresponding further giving way in prices. It is not improbable that the large stocks held at many of the collieries, and which there will now be no necessity to retain, will be a source of weakness, as it is not at all unlikely that these in many cases will be forced upon the market, and that to effect clearance sales some concessions upon current rates may be made. With regard, however, to the general quoted pit prices, although the tendency of the market will no doubt be in a weakening direction, it is scarcely probable that there will be any very material change as regards lower prices in this direction, as the exceptionally low point to which prices have been gradually forced down ever since the commencement of the year has much more than discounted the reduction in wages that has been agreed to by the Conciliation Board. In anticipation that amongst buyers there would be a good deal of pressure for some further concessions in prices, to accompany the reduction in wages, special meeetings of the various districts of the Lancashire Coal Sales Association were held in Manchester on Tuesday to consider what action should be taken with regard to prices, and in all cases resolutions were passed that the official list rates should remain unchanged—these resolutions afterwards being confirmed by the Council, and in the afternoon, at a general meeting of the Coal Sales' Association, a resolution was unanimously passed "that as the prospective relief in wages has been already discounted by the prices of fuel having been so materially reduced during the last few months, there be no further reduction in wages." Prices, however, are just now scarcely really tested, as there is so little business stirring, and they are for the moment barely more than nominal; quotations, however, remain at about 11s. to 11s. 6d. for best house-fire coals, 10s. to 10s. 6d. for second qualities, 8s. to 8s. 6d. for common house-fire coals, with steam and forge coals quoted at 7s. to 7s. 6d. at the pit mouth, although the minimum figures may be taken as representing more nearly the prices at which actual business would be done. With regard to engine fuel, supplies have become very plentiful in the market, and rather lower prices would be taken, common slack being obtainable at 3s. 9d. to 4s. 3d.; medium sorts, 4s. 6d. to 5s. 3d.; with best qualities quoted at 5s. 9d. to 6s. 3d. per ton at the pit mouth.

A general holding back from placing out further orders has also been noticeable in the shipping trade, this being due to the prevalent expectation of a reduction in prices, and very little business has been doing during the past week. Quotations, however, remain as last given, and for delivery at the ports on the Mersey about 9s. to 9s. 6d. per ton is still quoted for Lancashire steam coal.

Messrs. James Russell and Sons, of Wednesbury, have opened a warehouse at 33, King's-street, West Manchester, for the convenience of customers in this district.

*Barrow.*—No change can be noted in the condition of the hematite pig iron trade. Makers are very indifferently supplied with orders, and their trade is not sufficient to dispose of all the iron they make, even with only thirty-six furnaces in blast. The only department in the trade which is in any sense active is that of the local demand on the part of makers of steel. Prices are not practically changed. Hematite is still quoted at 43s. 11d. for warrants, sellers net cash, and 43s. 10d. buyers. Makers quote 1s. to 1s. 6d. per ton above these figures, but it is only special brands which can be sold at these figures, and all parcels are of small dimensions. Forge and foundry iron is extremely quiet.

Iron ore finds a poor market at present in Scotland, and the local trade is also very quiet. Old quotations are ruling, average qualities being at 8s. 6d., net, at mines, but it is impossible to get ore cheaper, as practically no profit is left to the raiser at this price.

Steel makers are busy at the plate mills, and to the ordinary home trade, a foreign and colonial business is being gradually added. There is a fair demand for shipbuilding material, and makers are still fairly supplied with orders. Heavy rails, are however, in quiet demand, and there is practically nothing doing in light, colliery, or tram sections. Only a poor business is reported in billets and tin-plate bars, while blooms, slabs, and wire rods are scarcely ever inquired for. Heavy steel castings are still in demand, and large forge work is brisk. Steel wire is very little worked in the district.

Shipbuilders and engineers are still very busy. The Barrow Company launched on Saturday the first of three torpedo-boat Destroyers of the Havock type, which are being built at Barrow. She was named the Sturgeon. This is the first torpedo-boat Destroyer which has been launched out of the twenty-seven which were ordered at the end of last year by the Admiralty. The Sturgeon, which is to steam 27 knots an hour, is being fitted with Bletchynden's patent water-tube boilers. The Naval Construction and Armaments Company has secured another order from the London County Council for a sludge boat to carry 1000 tons of sewage out to sea. This is the sixth order for this class of vessel which has been placed with the Barrow Company. The Unioni, a Norwegian oil ship, built at Barrow two years ago, has been brought to the Barrow yard for repairs after a collision with an iceberg in the Atlantic.

The coal and coke trades are very quiet. The demand is small, and the consumption is limited. Prices are steady.

Shipping is still further depressed. The exports of pig iron and steel from West Coast ports during last week were 22,352 tons, compared with 38,892 tons in the corresponding week of last year, a decrease of 16,540 tons. The shipments to date this year have reached 430,756 tons, compared with 424,760 tons in the corresponding period of last year, an increase of 5996 tons.

Stocks of iron in warrant stores have increased during the week 6024 tons, and now represent 155,606 tons, an increase since January 1st of 60,983 tons.

## THE SHEFFIELD DISTRICT.

(*From our own Correspondent.*)

THE strike in the North has not had the stimulating influence upon the South Yorkshire coal industry that was looked for. Large manufacturers and merchants appear equally disposed to wait for reductions, a circumstance which clearly indicates the real condition of the coal trade in this locality. The demand is about as it was before the Scotch strike occurred, the fluctuation in values which that dispute brought about for a short time having entirely disappeared. The fine weather, with recent developments in the wages question, has had considerable effect in restricting business. It has already been stated that the men strongly disapprove of the action of their leaders in conceding the 10 per cent. reduction, whilst many of the coalowners feel that the 30 per cent. minimum wage for two years will be a great drag on the trade. There is every evidence, however, that opposition will gradually be lessened and ultimately evaporate.

House coal is in quiet demand. No better reports are received from the London market, and quotations remain the same as last week. Prices have a downward tendency and merchants are not disposed for business at the present rates. The quotations for Silkstone house coal are 9s. 6d. to 11s. per ton; Barnsley house, 8s. 9d. to 10s. per ton; inferior qualities from 8s. 3d. per ton. The demand for steam coal is still well maintained, and accounts continue good from the Humber ports, the local ports having a large proportion of the trade. Barnsley hards are at 7s. 9d. to 8s. per ton; lower qualities, 7s. per ton. Gas coal is in moderate request at 7s. 6d. to 8s. 6d. per ton. Manufacturing fuel can be easily obtained at from 4s. 6d. to 5s. 6d. per ton. Poor demands are still reported for smudge and small coal, which is quiet at 2s. to 3s. per ton. Coke in fair request at 9s. to 11s. per ton.

Reports from abroad still confirm what has already been heard about trade depression in America and elsewhere. A Sheffield manufacturer, who has just returned from the United States, says that the production of pig iron in that country has fallen from over 9,000,000 tons per annum, when the Iron and Steel Institute were visiting the States, to between 3,000,000 and 3,500,000 tons. Mr. Abraham Hewitt, who is one of the leading ironmasters in America, states that in his opinion the cause of the falling off is over-production, and that until some of the old works have been weeded out, and the demand again increases, there will be but little change in the commercial situation so far as the American pig iron industry is concerned. Pig iron for steel-making costs in America about the same as it can be bought in England, but the price paid by American manufacturers for fuel is much lower than the price paid in this country. One firm in the United States, who bring their fuel a distance of 400 miles, actually pay less than Sheffield manufacturers, who buy it on the spot. This is one of the reasons why the Americans put their productions on the market at such rates as would barely leave any profit for their English competitors.

It was mentioned some time ago that a dispute had occurred at the works of Messrs. John Crowley and Co., ironfounders, Meadow Hall, and Kelham Ironworks, Sheffield. It terminated in the labourers coming out on strike for an advance of 2s. per week, and the moulders ceased work in sympathy with the labourers. It was pointed out at the time how unreasonable and how untimely the strike was. Work was very slack, and the condition of trade did not warrant any increase in wages. The men appear at last to have taken this view, for they have asked to be permitted to return to work at the old rate of wages, the company promising that when there is a revival in trade they will then consider what can be done. Business has been proceeding as usual during the dispute, and the firm will take on as many men as they can, consistently with dealing justly towards the new hands, who had offered their services and are now in their employment.

In last week's ENGINEER it was mentioned that Sheffield makers of military material had discovered the secret of the new Russian shell, which had given such good results against the Harveyed plates at Ochta, near St. Petersburg. Messrs. Thomas Firth and Sons, Norfolk Works, have written to the War-office and the Admiralty offering to supply samples of these shells in a few days if the authorities will undertake to have them fired. The improvement in the Russian projectiles is said to be one that can neither be patented nor kept long secret. At the same time the shell is admitted to be an advance upon anything that has been manufactured up to the present time. Shells on the new system are being prepared in Sheffield and are ready for trial. Experiments are shortly to be made with shells manufactured by the Hadfield Steel Foundry Company and other Sheffield firms.

Anxiety continues to be felt in commercial circles respecting the delay in passing the United States Tariff Bill. The Wilson measure proposes important reductions in the duties on various classes of pig iron, and makers in the Sheffield district are hoping that these changes will be effected. If the present proposals become law an active demand for iron for the American market is anticipated. As many furnaces are now idle and stocks are very low, a perceptible increase in the demand would at once send up prices. A revival in the iron trade would have the further gratifying effect of benefitting the coal industry. At present the inquiry for finished iron in its various classes continues dull, the consumers contenting themselves with ordering for immediate requirements. Hematites are still quoted at 51s. to 52s. 6d.; common forge iron from 37s. 6d. to 38s. per ton; bar iron £5 10s. to £5 15s.; iron sheets, £8 10s.; common wire rods, £5 5s.; Bessemer billets of guaranteed temper £5 7s. 6d. to £5 10s.

An improved demand is reported for heavier railway material, due chiefly to the setting in of a demand from railway companies, both in these and foreign parts. Rolling stock had been allowed to get so low, that the accession of fresh orders was merely a question of a short time. There is an idea that we are on the verge of an improvement in the railway material trade. Shipbuilding, on the other hand, continues as dull as ever. There is not sufficient employment for anything like the number of existing ships. Grain and wool, as well as silver, remain so low, that no improvement is possible until there is a change. No new ships will be placed upon the stocks so long as freights remain at these unprecedentedly low rates.

Our local firms concerned in the production of articles required for husbandry are still well off for work, in view of an expected abundant harvest. The outlook in the country is most gratifying on every side, and farmers are buying very freely the newest appliances for rapidly dealing with the getting and storing of the crops.

The lighter trades of the city continue as last reported. The American houses chafe over the suspense caused by the delay in the American Tariff; their heavy stocks still being increased to prevent discharging their men. Travellers give very poor reports of the London and leading provincial markets. The special season trade in prizes for competitions is keeping one department of several of our best electro-platers and silversmiths fairly busy. Edge tools are again in increased demand; the season in garden implements has also been a good one, and in the kindred departments there is no lack of work.

Mr. John Barker, manager of the Grimesthorpe Steel Works, belonging to Messrs. Charles Cammell and Co., has just retired after forty-five years' service. The managers and staff presented him with an address and a purse containing fifty guineas. Mr. Barker, in acknowledging the gift, gave some interesting facts. Amongst other things he mentioned that the annual production of steel in his department alone has for some time past exceeded the whole output of Great Britain when his business life commenced.

## THE NORTH OF ENGLAND.

(*From our own Correspondent.*)

WAGES questions form the chief subject of attention in connection with the trade of this district, and as long as the strikes continue there is not much chance of improvement. Though the Scotch miners' strike has caused such a marked decrease in the production of pig iron, it has led to very little increase in the demand for pig iron made in this competing district, indeed it has caused a decrease in the sale of all kinds of pig, except No. 3, as it has stopped so many local as well as Scotch works consuming Cleveland forge and hematite pigs. The strikes, however, which most injuriously affect the business of this district, are those of the moulders and patternmakers, which have now been in progress nearly nineteen weeks, and which, though directly affecting only some 1500 men, have thrown over 16,000 out of employment. Some efforts have during the last few days been made to bring about a settlement of the difficulty, but unfortunately they have as yet led to no result. The desirability of forming a Conciliation Board seems to be conceded by both sides, but they do not appear to be able to agree upon the terms. In the first place, the men's representatives suggested the Mayor of Newcastle as mediator, and offered to at once resume work if the employers would agree to the formation of a Conciliation Board with a neutral chairman. The employers thereupon offered that ten of their representatives should be appointed to meet an equal number of the representatives of the men under a neutral chairman—the Bishop of Newcastle—to arrange for the formation of the Conciliation Board, but they required that the men should at once return to work, and that they should entirely abandon the present claim for an advance of wages, while they stipulated that there was to be no interference with any men who have worked during the strike, and intimated that they could not, owing to scarcity of work, undertake to find employment for all the men now on strike. The following were the gentlemen appointed to act with the men in forming the Conciliation Board:—Sir Andrew Noble, Sir B. C. Browne, Messrs. George Clarke, J. H. Irwin, E. Towers, G. H. Baines, T. Richardson, T. Westgarth, J. Pilling, and Dalrymple. This offer of the employers was generally regarded as a fair one, but the men did not so esteem it, because they are not prepared to abandon their present claim for advanced wages, but want that to be referred to the proposed Conciliation Board. Nothing further has been done to bring about a termination of this most disastrous strike, a strike from which so many more than those immediately concerned are serious sufferers, and for their sakes alone something more should be done without delay to effect an adjustment of the difficulty.

The Cleveland ironstone miners set the moulders an example, for, seeing that trade has gone back, they have abandoned their claim for 7½ per cent. advance of wages, which they made several months ago, and have renewed since. With regard to the eight hours' movement at the blast furnaces in the North of England, the men have decided to hold their demonstration on Saturday, August 11th. They had intended that it should take place on a Wednesday, but finding that such an arrangement would lead to the stoppage of the Eston, North-Eastern, and Consett steel works, they decided to have it on a day of the week which would cause the least inconvenience to consumers, but whenever it may be held it is calculated that it will cause a loss of £30,000, because the men will sacrifice £10,000 in wages for their day's holiday, and the masters will lose £20,000. It was suggested at the recent conference of masters and men that if one of the firms connected with the Cleveland Ironmasters' Association would undertake, at the joint cost of the whole Association, to experiment on the eight hours' shift, with a view to its general adoption if it was found to answer, the men would forego the demonstration. But the employers were not prepared to agree to this. A Middlesbrough firm, outside the Association, is about to adopt the eight hours' shift, and two other firms—non-members—have started it. Under these circumstances it would appear the wiser course for the men to wait and see how the scheme works out, and then they would have an unanswerable case when, if successful, they claimed the general adoption of the eight hours. It is admitted that at present the matter is a question of experiment in the North of England, and the proposed demonstration is not likely to bring about its earlier adoption.

Owing to the strikes and the smaller consumption the pig iron trade is dull, and only for No. 3 Cleveland pig is there anything like a fair demand. That quality is needed more largely for export to the Continent; so much so that the shipments oversea this month are the largest that have been reported in July for many years, and are the heaviest of any month this year. The Continent is taking more than usual from this district because there is less to be had from Scotland, and, moreover, both prices and freights are low, and the carriage of the iron from the coast to the inland works is more easily and cheaply effected than is general at this time of the year, when usually the rivers are very low, and the barges can only be loaded to half their capacity. The total pig iron shipments from the Tees this month have reached 74,264 tons, as compared with 67,678 tons last month, and 65,650 tons in July, 1893, all to 25th. On account of the extra foreign demand for No. 3 the supply has been considerably reduced in makers' hands; in fact, the stocks at some of the works is entirely exhausted, and there are cases where makers are not able to deliver all the No. 3 they have contracted to supply. Yet in spite of this the value of No. 3 does not improve, because if it were put up consumers would buy warrants, and makers' iron can hardly advance when warrants do not move upwards. Thus the quotation for No. 3 Cleveland G.M.B. pig iron is kept at 35s. 6d. for prompt f.o.b. delivery, and not less is taken. No reliable price is ascertainable for forward delivery, as people are not prepared to buy. Cleveland warrants have moved very little this week, not more than a halfpenny, the quotation being 35s. 5½d. cash sellers. Little iron is being taken out of the public store, and on Wednesday night

Messrs. Connal and Co. held 97,594 tons of Cleveland pig, or 437 tons decrease this month. The demand for all other quantities of pig iron than No. 3 has slackened, and forge qualities have again become rather a drug upon the market, for while the output has been increased, the consumption owing to the strikes has fallen off, both locally and in Scotland. No. 4 forge is 34s. The same may be said of hematite iron, mixed numbers of which can be obtained at 43s. per ton, f.o.b. Foreign ore has dropped considerably in price, and whereas for months nothing less than 12s. 6d. per ton, delivered Tees, was taken for best Rubio ore, there have been sales at 11s. 9d., and 12s. will now be taken for forward delivery. Most of the makers of hematite iron are now well stocked with ore, and merchants who have cargoes coming in which are unsold, have some difficulty in getting rid of them if they stick out for more than 11s. 9d. The freight Bilbao-Tees has further fallen to 4s. 10½d.

The finished iron and steel manufactories are badly employed, especially the former, few doing more than run half time, and reductions in prices have no effect in tempting consumers. The nominal prices are:—Common iron bars, £4 17s. 6d.; best bars, £5 7s. 6d.; iron ship angles, £4 12s. 6d.; iron ship plates, £4 15s.; steel ship angles, £4 12s. 6d.; steel engineering angles, £4 17s. 6d., and steel ship plates, £4 17s. 6d., all less 2½ per cent., and f.o.t. Heavy steel rails are nominally £3 12s. 6d., and steel sleepers, £4 17s. 6d., both net and at works. The Consett Iron Company will pay 9s. per share to the ordinary shareholders, and the Consett Spanish Ore Company 5s. per share, which are £1 paid. The members of the North-East Coast Institution of Engineers and Shipbuilders visited the Consett Works a few days ago.

The half-yearly meeting of the Board of Conciliation and Arbitration for the Manufactured Iron and Steel Trades of the North of England, which has been in existence since 1869, is to hold its half-yearly meeting at Newcastle on Monday.

The shipbuilders of the North-East Coast have agreed with the Executive Council of the Boilmakers and Iron and Steel Shipbuilders' Society—the action of the latter being confirmed by the general body of the men, 15,950 being for and 11,940 against—that a Conciliation Board shall be formed, the scheme to be tried for five years, and to be afterwards terminable by six months' notice on either side. As to alterations in wages, it is agreed that no general alteration shall be made until after six calendar months have elapsed from the date of the last alteration, and that no single alteration be more than 5 per cent. A standing committee of three on each side—exclusive of the delegates on each side—shall be appointed for each river to consider local disputes.

The members of the Cleveland Institution of Engineers on Friday last visited the waterworks now in course of construction in Baldersdale for the Stockton and Middlesbrough Corporations.

A fair business is being done by the coal trade of this district, but the shipments are not equal to what they should be at this time of the year, especially when the whole of the Scotch collieries are idle. The Northumberland coal trade have established a Conciliation Board for the purpose of settling wages disputes. At the first meeting held on Tuesday, it was officially reported that the average realised price of Northumberland coal during the three months ended May 31st had been 6s. 4·72d. per ton, and the masters claimed a reduction of wages, as this figure was considerably below that of the previous quarter. It was decided that the reduction should be 5 per cent. The Northumberland and Durham Coal Sales Association has now been fully established, and among the subscribers are the Marquis of Londonderry, the Earl of Durham, Sir James Joicey, Bart., Sir Charles Mark Palmer Bart., Mr. Lindsay Wood, Mr. David Dale, and Mr. W. Stobart. The price of best Northumberland coal this week is 11s. per ton. Good Durham coke is firm in price, and 12s. 6d. per ton delivered Middlesbrough, can readily be got, while 12s. 9d. is generally asked.

## NOTES FROM SCOTLAND.

(*From our own Correspondent.*)

THERE has been very little doing in the Glasgow iron market this week. The transactions in warrants have been confined mainly to what was incident to former accounts. Operators continue to keep out of the market and consumers are quite indifferent, their wants at the moment being few and unimportant. There is comparatively little change in the price of warrants.

The special brands of makers' iron show a decided advance, owing to their scarcity and to so many furnaces being out of blast. G.M.B. f.o.b. at Glasgow No. 1 is quoted 43s. 6d. per ton; No. 3, 42s. 6d.; Monkland No. 1, 47s.; No. 3, 42s. 6d.; Carnbroe No. 1, 48s.; No. 3, 45s. 6d.; Clyde No. 1, 54s.; No. 3, 48s. 6d.; Calder No. 1, 54s. 6d.; No. 3, 48s. 6d.; Summerlee No. 1, 55s.; No. 3, 48s. 6d.; Gartsherrie No. 1, 57s. 6d.; No. 3, 48s. 6d.; Coltness No. 1, 57s. 6d.; No. 3, 52s. 6d.; Glengarnock at Ardrossan No. 1, 52s.; No. 3, 48s 6d.; Eglinton No. 1, 50s.; No. 3, 45s. 6d.; Dalmellington No. 1, 49s.; No. 3, 45s. 6d.; Shotts at Leith No. 1, 55s.; No. 3, 51s. 6d.

The shipments of pig iron from Scottish ports in the past week amounted to 3600 tons, against 4821 in the corresponding week of last year. There was despatched to Canada 207 tons, South America 100, Australia 130, France 315, Germany 140, Holland 921, Belgium 40, other countries 115, the coastwise shipments being 1632, against 2712 tons.

Since last report seven additional furnaces have been put out of blast. There are now in operation three at Coltness, four at Shotts, and four at Glengarnock, total blowing in Scotland eleven, as compared with eighteen last week, and sixty-two at this time last year.

The market for manufactured iron and steel continues quite inanimate. Very few of the works have yet resumed, and there is no change in the position of business, which is that of complete stagnation.

The iron and steel manufactured goods shipped from Glasgow in the past week embraced sewing machines worth £8645; other machinery, £27,233; steel goods, £4880, and miscellaneous iron goods, £21,145.

At most of the shipyards in the Glasgow district the holidays are now over, work having commenced on Tuesday last. It is reported that many builders and engineers have good supplies of coal in stock, which will last in some cases four or five weeks.

The prospects of the locomotive engineering department are fairly satisfactory. Messrs. Neilson and Co., of Glasgow, have received an order for ten heavy locomotives for the Great Indian Peninsular Railway, and Messrs. Dubs and Co., of the Glasgow Locomotive Works, have obtained an order for engines from Russia, as well as from the Midland Railway.

The coal market continues disorganised owing to the miners' strike, which has now lasted for about five weeks. The holidays have of course greatly curtailed the demand, but those who are in want of coals have little difficulty in obtaining supplies, there being plenty on offer both from Fifeshire—where considerable stocks are kept—and from England and Wales.

Great distress already prevails in a number of mining districts, the miners and their families being reduced to the necessity of begging for their daily bread. The support sent from England, although no doubt generous enough from the point of view of the English miner, has proved altogether inadequate to meet the necessities of from 60,000 to 70,000 miners and their families. As for the employers, they appear quite resolved to wait until the men ask to be re-admitted to the mines, and so much injury has been done to trade by the strike, that it is doubtful whether the miners will be allowed to resume at the old wages. The pig iron industry has of late years repeatedly been subjected to very serious loss by strikes of miners, and the almost complete stoppage of the manufacture, on this occasion, shows how resolute the ironmasters are, and how hopeless the position of the men on strike. The miners' leaders have, so to speak, struck down the iron industry for the time, and in iron circles any proposals for arbitration are regarded as utterly futile.

## WALES AND ADJOINING COUNTIES.

(*From our own Correspondent.*)

THE inquiry into the Albion explosion still continues, and a mass of evidence has been given by the various witnesses, including one or two survivors, who were able to describe the actual state of things just previous to the disaster. The under-manager, examined on Tuesday, had formed a similar opinion to that expressed by the manager, as to the starting point of explosion in Grover's level, and to the probable cause—a large collection of gas dislodged from a cavity by a great fall. Upon this head, methods of blasting, watering, "bashing," sending out rubbish instead of building them up, testimony is borne that will be of importance in assisting to give a decision, and no doubt will be valuable in directing operations in the future. The very fact that there were men in the first shift, who went on again in the second shift, points out one probable cause—the haste of the men to "rush out coal," and possibly to the neglect of wise precautions for their own safety. Another body was brought up this week.

There has been no falling off in the coal trade, and in every direction a good deal of vigorous work is being done, both with regard to existing collieries and in sinking new ones. The Tredegar Company, by sinking to the deep at the Pochin Collieries, will inaugurate another bold winning of the lower measures of Monmouthshire, a good deal of which remain practically intact, considering the large area. It is interesting to note that great iron companies, such as Gadlys, Abernant, Plymouth, Rhymney, and Tredegar, are now solely devoted to coal getting, and the "iron works" are represented by a few fitters, smiths, and others.

It is a debateable subject in the district, that an ironworks laid by rarely, if ever, resumes operations. Still, with regard to Rhymney and Tredegar, which are well equipped with the best steel plant, I do not see any reason to doubt but that a restart might follow in the track of better times in steel. The public will be in a position to form a shrewd judgment regarding the steel work on the hills when the full completion of "Dowlais-on-sea" has been brought about. This is being rapidly done. It would have been very opportune to have finished the works, and completed the sinking of the Dowlais Cardiff Collieries at the coming of age of the heir of Lord Wimborne, but I do not think that this is practical.

A local authority comments with some force upon the various schemes of the year, illustrating the industrial progress of South Wales. These I have touched upon as they have been brought to the front. First among these is the Bute Docks addition, which, when completed, will give Cardiff a high position amongst the leading ports of the country. One significant point concerning this addition is the deepened channel which is intended, and is to be constructed with a view to admit of steamers of 5000 to 10,000 tons, which the commentator justly observes, "are to be the boats of the future."

Next in importance come the Port Talbot Dock and Railway. This, and a railway to Maesteg, will bring a great tract of coal country into full development. It is pointed out that at present coalowners shipping from this district at Cardiff pay 1s. 4d. to 1s. 6d. The Maesteg line, connected with Port Talbot, will do this for 6d. per ton. Some may think that this will tell seriously upon Cardiff, but I have a strong belief that, as in the case of Barry, there will be ample business for all.

The prophets, who anticipated a decline in steam coal prices, are "out" completely. Present quotations on Cardiff Exchange are as firm as ever. Latest mid-week prices were: Best steam, 12s. to 12s. 6d.; seconds, 11s. 6d.; best Monmouthshire, 11s. to 11s. 6d.; dry kinds, 10s. 6d. to 10s. 9d.; small, 6s. to 6s. 6d. House coal keeps up unusually well, and the slack and depressed season, both in quantity and price, appears to keep aloof. It was noticed on 'Change this week that booking forward was exceptionally brisk. Latest prices are:—Best, 11s. to 11s. 3d.; No. 3, Rhondda, 10s. 9d. to 11s.; brush, 8s. 9d. to 9s.; small, 6s. 9d. to 7s.; No. 2, Rhondda, 10s. to 10s. 3d.; through, 7s. 3d. to 7s. 6d.; small, 5s. to 5s. 3d.

Coke has begun to show greater firmness; the demand is better, and prices firm. Latest are:—Cardiff: Furnace, 15s. to 16s.; foundry, 17s. to 17s. 6d.; and special, 20s. to 21s. Pitwood and patent fuel in moderate request; prices unchanged. Swansea has had another good week of patent fuel shipments, France taking 2130 tons, Turkey 2200, Italy 3950, and Algeria 1550 tons. Swansea price, 10s. 6d. to 11s. For iron ore the requirement is less. Good cargoes continue to arrive, the principal going to Tapson and Son, La Société Commerciale, Ebbw Vale Company, and Blaenavon. Figures are lower. Rubio is quoted at 11s. to 11s. 3d.; Tafna and Garucha, 10s. 6d.; and Porman, 10s. Pig iron stocks are large at various places, and the import also is large from Middlesbrough and other quarters. Last week Swansea imported 590 tons.

Swansea coal quotations are:—Steam coal, from 11s. 6d.; No. 3 Rhondda, from 11s.; anthracite, from 8s. 9d. to 12s. 6d., according to quality.

There is little or no change in the iron and steel trades, and make continues moderate, even in steel bar. Steel rails, though admittedly at the lowest point in price, are only in slight demand. The latest quotations on 'Change, Swansea, this week were as follows:—Glasgow pig, which has taken a stationary position, 41s. 11d. to cash buyers; Middlesborough, 35s. 5d.; hematite, 43s. 7d. for mixed numbers f.o.b.; Welsh bars, £5; sheet iron, £5 15s. to £6 10s.; steel sheets, £5 to £6 5s.; steel rails, heavy section, £3 15s. to £4; light, £4 7s. 6d. to £4 10s.; sleepers, angles, channels, &c., according to section and specification.

Bessemer steel:—Tin bars, £4 to £4 2s. 6d.; Siemens best, £4 2s. 6d. to £4 5s. Cardiff prices vary slightly from this. Bessemer blooms are offered at £3 17s. 6d.; tin plate bar, £4 5s.; and Siemens best, £4 5s.

I am glad to continue favourable reports of Briton Ferry. This week six mills were at work at the Villiers, four at Vernon, three at Baglan Bay, and three at Gwalia. The make of pig iron and steel bar is well maintained, and demand, I hear, is quite up to the make.

The history of the iron and steel trade of Wales, from earliest times to the present, is one of the forthcoming works, uniform with the history of the coal trade. In it, amongst a variety of interesting annals of men and works, we are told all that is known of Trevitheck, and his labours in Wales. Our South Wales correspondent mentioning it, says, I have lately been upon the track of his earliest locomotive, which ran along the Merthyr tramway in 1804. Many persons imagine that it is in the Kensington Museum, and several have declared that it was exhibited at Tynemouth Museum. The fact is that, after doing duty on the tramway, it was relegated to pit work. The Penydarran Company, in sinking their deepest pit, utilised it at Winch Vaun, by the side of the Penydarran incline, and there it was to be seen, old people aver, "with the piston fastened in the boiler, and with three cocks doing duty instead of safety valves." Then it was put to work at the incline, was "restored" bit by bit, and finally disappeared. I do not despair, however, yet, of getting a fragment.

Swansea harbour trade continues satisfactory, the only decline being in tin-plate, which is going through a course of "ups and downs." Short delivery continues to be the leading feature, and the thirty-six box rule promises to assume a critical form, leading to important stoppages, unless the men exercise common sense. The engineer to the Trust has been instructed to prepare working plans for the extension of the Prince of Wales Dock. Permission has been given to the executors of the late Mr. Walker to make an entrance from the Prince of Wales Basin to their proposed Commercial Dry Dock. Mr. Westlake proposes to construct a pontoon, gidiron, &c., for the repair of vessels of the largest channel capacity.

A meeting of the Albion colliers was held on Monday to consider a proposal from the manager of the colliery, that they should revert to the system which was in vogue before the explosion, of working daily shifts of ten hours. This was discussed and refused, so a temporary halt has been the result. Mr. W. T. Crawshay has generously given £100 in aid of the widows and orphans of the calamity.

Newport coal trade is very brisk. The Plymouth strike, which has lasted seventeen weeks, to the grave detriment of funds, has come to an end, with some slight but acceptable concessions.

Tin-plate shipments last week only amounted to 37,079 boxes; receipt from works, 49,570 boxes; present stock, 289,597 boxes. Latest prices tin-plates, Swansea:—Bessemer cokes, 10s. 3d. to 10s. 4½d.; Siemens, 10s. 4½d. to 10s. 7½d.; best charcoal, 11s. 6d. to 12s. 6d.; ternes, 19s. to 23s. Wasters, 6d. to 1s. less than primes; odd sizes, usual extras; all delivered in Prince of Wales Dock, Swansea. Cash, usual discount.

Block tin is at £66 15s. to £67 5s.

The Western Wagon Company, Bristol, again show good results. The directors recommend a dividend of 8 per cent.

Coal and iron shares are moderately good. Albions are about 11¼, W. Dawes and Sons 13$\frac{5}{16}$, Norths £2 12s. 6d. Rhymney iron, old, 32s. The new shares are brisk at 17s. and 16s. 9d.

## NOTES FROM GERMANY.

(*From our own Correspondent.*)

THOUGH general iron business over here does not show much animation, the tendency of prices may still be called a pretty firm one. For export there have been very few inquiries stirring, but the demand experienced on home account remains fairly satisfactory, so that the majority of the works report themselves tolerably well engaged.

A somewhat better tone has manifested itself on the Silesian iron market this week. The orders that come in for bars and sectional iron, though of small weight generally, have increased in number. The business in heavy plates continues weak, but that in sheets is decidedly improving. Tube foundries as well as wire mills are likely to be well engaged for some time to come, a fair amount of new work having come to hand lately, while at the machine factories but very few orders are being booked.

In Austria-Hungary the iron industry continues well employed in all departments. The demand for pig iron is good, and that for malleable iron has been decidedly satisfactory all through last week. Here and there fair orders for building requirements have been secured, and it is now considered as tolerably certain that autumn business will develope quite favourably. An advance in quotations has not yet been taken into consideration, but it is very probable that prices will soon show an inclination to rise.

The situation of the French iron business remains pretty favourable, for both raw and finished iron orders are coming in regularly; and although the prices paid leave, on the whole, but little profit, the tone of the market is hopeful and firm, the more so as there is good reason to expect a lively autumn business.

In Belgium the pig iron trade is still languid, and there has been next to no inquiry coming forward in the finished iron department. Prices are, nevertheless, pretty firmly maintained this week, and the general tendency is, perhaps, less despondent than formerly. Comparing the quotations of June and July of present year, no change whatever is noticeable except in plates, No. 2 having advanced from 130f. p.t. on 132·50f. p.t., while No. 3 rose from 150f. on 152f. p.t.; steel plates also advanced from 140f. on 142·50f. p.t.; sheets are still quoted 160f. p.t., and steel rails also remain on 95f. p.t. The number of blast furnaces in blow on the 1st of July was the same as in the beginning of June. The following shows the production of pig iron in Belgium for June and during the first quarter of 1894 and 1893:—

| | June. | | January to June. | |
|---|---|---|---|---|
| | 1894. | 1893. | 1894. | 1893. |
| | Tons. | | Tons. | |
| Forge pig.. .. | 36,600 .. | 34,350 .. .. | 189,220 .. | 211,670 |
| Foundry pig .. | 7,050 .. | 6,600 .. .. | 47,415 .. | 39,820 |
| Basic.. .. .. | 34,500 .. | 21,300 .. .. | 207,150 .. | 127,625 |
| Totals .. .. | 78,150 .. | 62,250 .. .. | 443,785 .. | 379,115 |

Although the Rhenish-Westphalian iron market has but slightly changed since last week, that change has, generally, been in the direction towards improvement. Prices for raw as well as finished iron are, as a rule, decidedly unremunerative, and in no proportion to those of the raw materials, but as there has been an improvement in the demand for some sorts lately, the more sanguine ironmasters think an advance in quotations is very likely to follow. The iron ore trade is quiet, but all things considered, there is not much cause for complaint, consumption being about equal to production, while prices show a pretty firm tendency, both in Siegerland and Nassau. Spathose iron ore fetches M. 7·40 to 7·90 p.t.; for roasted do. M. 11 to 11·50 p.t. is given. Nassau red iron ore, 50 p.c. contents, costs M. 9·20 p.t. free Dillenburg.

A fair demand is experienced in Luxemburg-Lorraine minette, and prices have stiffened a little; for red minette, 40 p.c. contents, M. 3·40 p.t. is given, while inferior qualities are noted M. 2·40 to 2·70 p.t. net at mines. For crude iron the demand has, in a few instance, improved, and the further development of the pig iron business is looked forward to with confidence. In the Siegerland the demand for some requirements has been steady, and prices are fairly maintained; orders from abroad still come in very slowly.

The price noted for spiegeleisen, 10 to 12 p.c. grade, is still M. 52 p.t.; Rhenish-Westphalian forge pig, No. 1, M. 46 to 47; No. 3, M. 40 p.t.; Siegerland good forge quality, M. 44 to 45 p.t.; hematite, M. 45 p.t.; foundry No. 1, M. 63 p.t.; No. 3, M. 54 p.t.; basic, M. 45 p.t.; Bessemer, M. 49 to 50 p.t.; iron for making steel, Siegerland sorts, M. 45 p.t.; Rhenish-Westphalian brands, M. 47 p.t. at works; Luxemburg forge pig costs 48f. p.t. free Luxemburg. Makers of manufactured iron report themselves fairly well occupied, the demand for bars having slightly improved upon the week. Girders are in moderate request, and prices continue depressed, Hoops are rather brisk of sale and pretty firm in quotation. The plate and steel trade is in exactly the same position as during former weeks, and there is also not the slightest change noticeable in the wire department, demand and sale remaining extremely limited. A pretty large outturn is going on at the tube mills, prices have shown a stiffening tendency; the machine and wagon factories, on the other hand, are extremely short of orders, and complain of unremunerative quotations.

The following are the latest list prices per ton at works:—Good merchant bars, M. 110; angles, M. 120; girders, M. 90 to 95; hoops, M. 113 to 118; billets in basic and Bessemer, M. 81; heavy plates for boiler-making purposes, M. 150; tank do., M. 130 to 135; steel plates, M. 125; tank do., M. 115 to 120; sheets, M. 140; Siegen thin sheets, M. 130; iron wire rods, common quality, M. 115 to 120; drawn wire in iron or steel, M. 105 to 120; wire nails, M. 125; rivet iron, M. 130; rivets, M. 150 to 155; steel rails, M. 112 to 115; steel sleepers, M. 106; fish-plates, M. 115; complete sets of wheels and axles, M. 270 to 280; axles, M. 220; steel tires, M. 215 to 230; light section rails, M. 95.

The total production of pig iron in Germany, including Luxemburg, was for June of present year 471,922 t., of which 127,430 t. were forge, pig, and spiegeleisen; 54,059 t. Bessemer; 214,473 t. basic; and 75,970 t. foundry pig. Output in June, 1893, amounted to 409,473 t.; in May, 1894, production was 468,981 t. From January 1st to June 30th, 1894, 2,649,071 t. were produced, against 2,401,960 t. for the same period the year before.

THE GEOLOGISTS' ASSOCIATION.—This Association will commence their long excursion to the County of Shropshire on July 30th, at Wellington, ending up on August 4th, at the same place. Members who wish to join excursion should notify their intention to the excursion secretary, Mr. Thomas Leighton. They should also apply for the programme, which is most complete, including all necessary maps, sections, &c., and railway arrangements.

## AMERICAN NOTES.

(*From our own Correspondent.*)

NEW YORK, July 19th.

THE situation from the manufacturing standpoint can be clearly seen by reference to the report of railroad earnings for June, which shows them to have been 21·84 per cent. below gross earnings of June last year. The railroad strike is said to be over, but the strikers have not formally yielded. Railroad earnings fell by one hundred million dollars for the first six months. During that time 25 per cent. of the reporting railroad mileage went into receivership, which is temporary bankruptcy.

Prices are declining. The iron trade is dull. Blast furnace production is increasing. Forge is 10 dols. to 11 dols.; Bessemer, 13 dols.; billets, 19 dols.; steel rails, 24 dols. There is no disposition to enter into contracts for full delivery. The rolling mill facilities were never in more complete shape for cheap and rapid work. The industrial stagnation may be terminated very suddenly, and buyers will then find themselves facing an empty market. Prices cannot much longer continue at almost the cost basis.

## LAUNCHES AND TRIAL TRIPS.

On Thursday, the 19th inst., there was launched from the yard of the Tyne Iron Shipbuilding Company, of Wellington Quay-on-Tyne, a steel screw steamer, built to the order of Messrs. Burrell and Sons, of Glasgow, and of the following dimensions, viz.:—Length, 350ft.; breadth, 43ft.; depth, 30ft.; and to class 100 A1 at Lloyd's on the spar deck rule. This vessel has water ballast fitted right fore and aft, on the cellular system, and is also fitted with all modern improvements for the rapid loading and discharging of cargo, including six double-cylindered steam winches, direct-acting steam windlass, large multitubular donkey boiler, steam steering gear by Messrs. Caldwell and Co., and Hastie's screw gear aft. The engines, which are to be supplied by the North-Eastern Marine Engineering Company, are of the triple-expansion type, having cylinders 24in., 40in., and 66in. by 45in. stroke, with two single-ended boilers fitted with Howden's system of forced draught, to work at a pressure of 170 lb. The vessel on leaving the ways was named the Strathneyis, by Miss Bone, of North Shields.

On Thursday, the 19th inst., Messrs. Palmers' Shipbuilding Company launched from their yard at Jarrow-on-Tyne the steamer Ranza. She is of steel, build on the three-deck class, and her principal dimensions are: — Length, 410ft.; breadth, moulded, 49ft.; depth, moulded, 34ft. She is constructed to carry fully 8000 tons deadweight on Lloyd's summer freeboard. The owners are Messrs. the Caledonia Steamship Company, of Liverpool, one of whose steamers, the Ratho, built in the same yard and with the same general features, has run with special success and economy. The engines will have cylinders 27in., 44½in., and 73in. in diameter by 48in. stroke, and steam is to be supplied by three large single-ended boilers. The engines and boilers are also built by Messrs. Palmers, and the hull and machinery are being constructed under the superintendence of Messrs. Flannery, Baggallay, and Johnson, of London and Liverpool, who are the owners' regular consulting engineers. Exceptional facilities will be offered for loading and discharging the cargoes, and there are six winches and portable derrick posts in addition to the usual fittings at the masts. She will be one of the finest and most modern equipped cargo steamers afloat, and has been laid down for quick service, and is designed for high speed at sea.

A few days since there was launched from the yard of Earle's Shipbuilding and Engineering Company, Hull, the new steel twin screw steamship Vienna, the fourth of a fleet of handsome vessels built by them for the Great Eastern Railway Company's new route to the Continent, *viâ* the Hook of Holland. The previous boats now on the station are the Chelmsford, Berlin and Amsterdam. The Vienna is 302ft. long, 36ft. beam, and 16ft. 3in. depth of hold, and she is built with a long partial awning deck and poop, under the former of which are situated the first-class dining saloon, ladies' room, state-rooms, lavatories, and the accommodation for officers, together with pantries, bar, galley, &c. On the lower decks, and entirely forward of the machinery and boilers, are the first-class state-rooms, with separate compartment for ladies where desired; and in a large deck-house on the awning deck are the saloon entrance, state-rooms, and captain's room, with a spacious trunk skylight for light and ventilation to the saloon. The total number of first-class passengers provided for is 218, and the whole of the fittings and equipment for these are of the most modern and complete description, every detail being carefully considered which might add to the comfort of the passengers, and the arrangement is generally the same as in the Chelmsford, but with various additions and extensions with the object of increasing the efficiency, amongst these being a handsome state-room capable of being divided, when required, into two, and constructed of polished hard woods of special design, this being intended for the accommodation of distinguished passengers. The system of fan ventilation now adopted in all the Great Eastern Railway steamers is in this one extended and elaborated so as to obtain a most ample supply of fresh air to the various spaces, and steam coil stoves are provided for heating the vessel throughout. The second-class accommodation is of a very comfortable kind, and established in the poop and after 'tween decks for 120 passengers. The Vienna will be schooner rigged with two light pole masts. Three powerful winches, with derricks and gear, are fitted for working the cargo, which, although quite subordinate to the passenger accommodation, requires to be handled with great despatch. Provision is also made in the 'tween decks forward for the carriage of horses. Water ballast for trimming purposes is also provided, and the equipment of boats will be stowed on a boat deck overhead, which will afford rain shelter for passengers besides forming a promenade on top. There are two sets of triple-compound engines to develope 4500 indicated horse-power collectively, steam being supplied by five large steel boilers. For use in calm weather and to ensure a good supply of air to the furnaces large fans will be fitted in the engine department, and the machinery generally is of the most modern type, and designed to meet all the requirements of their high rate of running. The speed expected to be attained by the Vienna is 18 knots.

On Tuesday, the 17th, the steel screw steamer Ceylon left the Cleveland Dockyard of Sir Raylton Dixon and Co., Middlesbrough, for the purpose of testing the general working of the vessel and her machinery by a run along the coast. This steamer has been built for the Peninsular and Oriental Steam Navigation Company, of London, being the third which these builders have constructed for the same company, and the Ceylon is fitted and finished in a very similar manner to the s.s. Aden, completed about two years ago for the same company's Eastern Line. The principal dimensions are: Length 390ft., beam 47ft., depth moulded 30ft. 10in., with a deadweight carrying capacity of about 6000 tons. The steamer is of the three-decked type, and takes Lloyd's highest class, but many of the scantlings are in excess of Lloyd's rules. She has also been built to fulfil the Admiralty requirements for unarmoured transports. The midship part of the vessel is very handsomely fitted up for the accommodation of first-class passengers, the saloon being tastefully decorated and panelled in white oak. Bath-rooms, lavatories, awnings, pneumatic bells, &c., are in sufficient number to ensure the comfort of the passengers at sea, and a spacious promenade deck extends the whole length of the bridge-house. The vessel is lighted throughout by electricity, and the 'tween decks are available for carrying troops or third-class passengers, being fitted with the necessary latrines, cooking and washing arrangements, &c. All the exposed decks are of teak, and the main deck is of steel sheathed with pitch pine, the orlop deck being of pine. The deck machinery for the working of cargo comprises seven large steam winches and two powerful cranes, the masts being fitted with double derricks and outriggers. The engines are by Messrs. Thos. Richardson and Sons, of Hartlepool, the cylinders being 30in., 49in., 77in., by 48in., with two large double-ended steel boilers, the propeller being of manganese bronze. The hull and the machinery of the steamer have respectively been constructed under the supervision of Captain C. E. Baker, who will command the ship, and Mr. J. W. Sellex, chief engineer. A large party of friends were present, at the invitation of Sir Raylton Dixon, and the owners were represented by Captain Angove, marine superintendent, and Mr. Manuel, superintending engineer, who expressed themselves very highly satisfied with the manner in which the contract had been carried out in every respect. The speed attained was 14·3 knots per hour, everything working satisfactorily. At the termination of a most successful trial trip, the steamer returned to the Middlesbrough Dock, where she will ship about 3000 tons of iron and coal, and then proceed to London to complete her cargo for India and China.

LEEDS ASSOCIATION OF ENGINEERS.—On Saturday, July 14th, the members of this Association visited Wakefield, and proceeded to the works of the Seamless Steel Boat Company, when they were met by Messrs. Richardson and Wright. The seamless steel boats, the manufacture of which was commenced at these works in 1890, are made in various sizes, from 15ft. to 30ft. in length. The 15ft. boats are pressed out of one sheet, but larger boats are composed of two plates, one on each side, with a strong T bulb bar between, forming the stem, stern, and keel. The two sides and keel bar are punched and riveted by hydraulic pressure. The press in which the boats are made is about 34ft. long, worked by six rams of 15in. diameter each, with a pressure of 875lb. per square inch. This press and the whole of the hydraulic machinery are by Messrs. Henry Berry and Co., of Leeds. There is also a very large plant for the deposition of zinc on the boats by electrolysis, which prevents corrosion in sea-water, and is, of course, applicable to any kind of ironwork required to withstand the weather. The boats are now in large demand by leading steamship companies. The party next proceeded to Messrs. Spurr, Inman, and Co.'s Calder Vale Boiler Works, where they were met by Mr. Sheard, managing director. The first machine to which he drew attention was a bending machine with four rollers, which would bend a plate 1⅛in. thick by 7ft. wide right up to the extreme ends, no hammering being necessary, as was formerly the case with the three-roller machine. The rollers are vertical, so that the edges of the plates are not damaged. After the plates are bent, they are placed in a machine built like a vertical lathe, which turns up the edges, and afterwards, by means of a slotting arrangement, slots each end. The shell courses thus prepared for drilling are lifted on to the drilling machine by a powerful travelling crane. There are three of these machines, enabling the firm to drill 15,000 rivet holes per week. The riveting is done by hydraulic machinery having pumps recently supplied by the Leeds Engineering and Hydraulic Company. The flues are welded by a steam flue-welding hammer made by Messrs. Pilkington, of Accrington. After being flanged, they are turned up on their edges, drilled, and riveted, a pressure of 45 tons being put on each rivet. The circular-end plates having been flanged and turned up on their edges, flue openings cut out, oval manholes cut out at one operation, and the boiler completed, a huge travelling crane lifts it to its place in the yard. The party had also been invited to inspect the works of Messrs. J. Rhodes and Sons. There they were met by Mr. George Rhodes, who drew their attention to the numerous improved presses, dies, and special machines designed by his firm for producing with great rapidity almost every description of sheet metal goods, from match-boxes to travelling trunks, &c. Metal casks to contain from 36 gallons are stamped out in four pieces, ingeniously bent, and securely fastened together. Other specimens of work were equally novel and interesting.

## THE PATENT JOURNAL.

*Condensed from "The Illustrated Official Journal of Patents."*

### Application for Letters Patent.

⁂ When patents have been "communicated" the name and address of the communicating party are printed in italics.

*11th July*, 1894.

13,426. Sley Caps, L. Bulcock and W. J. Threlfall, London.
13,427. Fixing Broom Handles, L. Bulcock and W. J. Threlfall, London.
13,428. Pneumatic Tire Pumps or Inflators, A. E. Moore, Dublin.
13,429. Automatic Door Holder, A. E. Moore, Dublin.
14,430. Puzzle, R. G. Graham, London.
13,431. Preventing Pipes Bursting, C. M'Carthy, London.
13,432. Hair-curling and other Pins, J. Leoboldti, London.
13,433 Electric Telegraphy, C. J. A. Munier, London.
13,434. Optical Lanterns, S. J. Levi and A. J. Jones, London.
13,435. Stud for Wearing Apparel, H. H. Lake.—(*A. F. Richter, Germany*)
13,436. An Ointment, E. Hopkins and E. Frost, London.
13,437. Camera "Magazine Backs," J. McL. Dobson, Lanarkshire.
13,438. Trousers Protector, H. M. Lynn and R. E. Caunter, London.
13,439. Apparatus for Drying Tea, H. Hemans, London.
13,440. Destroying Insects on Plants, P. P. Gieve, London.
13,441. Cycle Adjusting Pins, F. and E. Warwick, Birmingham.
13,442. Puzzle or Game, J. G. East, London.
13,443. Fast Dyes, C. D. Abel.—(*The Actien Gesellschaft für Anilin Fabrikation, Germany.*)
13,444. Curtain Poles, W. Woolf, London.
13,445. Signal Whistles, Alarms, &c., L. P. Garrett, London.
13,446. Siccative Drying Ointments, O. Troplowitz, London.
13,447. Sash Fastener, A. J. Ball and J. C. Hickton, London.
13,448. Ships' Hatches, J. Lefeuvre, London.
13,449. Perambulators, W. Andrew, London.
13,450. Breech Mechanism for Guns, A. Welin, London.
13 451. Velocipedes, S. Dyson, London.
13,452. Garment Supporters, F. G. Davis, London.
13,453. Miners' Safety Lamps, J. A. Noel, London.

*12th July*, 1894.

13,454. Appliances for Shipping Coal, C. R. Soar, Derbyshire.
13,455. Anchor, A. E. Muirhead, Glasgow.
13,456. Preventing Yarn from Twisting, D. and J. Smith, Blackburn.
13,457. Wire Fabrics, W. Waterhouse and T. W. Blantern, Birmingham.
13,458. Pannier Net Shafts, H. W. Rowland, Liverpool.
13,459. Clearers for Spinning Machines, G. Paley, Preston.
13,460. Velocipedes, G. L. Scott, Manchester.
13,461. Water-closets, J. Shanks, Glasgow.
13,462. Manufacture of Wood Pulp, T. Thornley, Manchester.
13,463. Rests for Billiard, &c., Cues, G. Moore, jun., Birmingham.
13,464. Construction of Waistcoats, W. C. Butler, Edinburgh.
13,465. Construction of Shirts, W. C. Butler, Edinburgh.
13,466. Divider Attachment to Scale Rules, E. H. Blake, Reading.
13,467. Rail Joints for Railways, E. Rees, Blaenavon, Mon.
13,468. Shuttle Guard for Looms, T. Ashworth, J. Rawson, and J. T. Cornall, Rochdale.
13,469. Dark-room Lamp, J. Davies, Birkenhead.
13,470. Iron Picker for Looms, A. Mosley, Huddersfield.
13,471. Wood Pavements, T. Gare, Manchester.
13,472. Construction of Cloth, J. G. Brook and A. Beaumont, Huddersfield.
13,473. Clothes Pegs, J. R. Brailsford and Vann and Co., Birmingham.
13,474. Apparatus for delivering Goods in Exchange for Coin, H. Millar, Newcastle-on-Tyne.
13,475. Stoppering Barrels, &c., J. S. Lowe, Birmingham.
13,476. Steam Boiler Furnaces, W. McG. Greaves, Manchester.
13,477. Automatic Barrel Tilters, J. Ames, Manchester.
13,478. Electric Arc Hood, S. G. Brown, Chelmsford.
13,479. Bottom Brackets for Bicycles, W. Smith and W. R. Fletcher, Birmingham.
13,480. Newspaper Reading-stand, H. A. Shuttleworth, Birmingham.
13,481. Driving Gear for Cycles, C. B. Lawson, Glasgow.
13,482. Preventing Vibration in Road Vehicles, W. Jones, Glasgow.
13,483. Cord for Window Blinds. A. Bell, London.
13,484. Trusses for Surgical Purposes, W. D. Lewis, London.
13,485. Alarm Bell, G. Leclercq.—(*F. Marti, France*)
13,486. Puzzle Game, J. Benford, E. J. Hayball, and H. Harcourt, London.
13,487. Towel Roller, J. Titley, Staffordshire.
13,488. Cycle Pedals, R. Wootton and B. Hewitt, Birmingham.
13,489. Steam Trap, J. Schofield, Manchester.
13,490. Counting Apparatus for Typewriters, W. Ollerhead, London.
13,491. Lock as a Sash Fastener, C. Barr, London.
13,492. Manufacture of Alcohol, R. Zdarck London.
13,493. Anchors, F. A. Crispin, London.
13,494. Soles for Boots and Shoes, T. Newman, London.
13,495. Portable Stands, J. R. Selbach, London.
13,496. Stirrup, W. P. Thompson.—(*J. M. L. Haddorf and H. F. H. Egyers, Germany.*)
13,497. Combined Walking-stick and Pipe, W. P. Thompson.—(*H. Wimmel, Germany*)
13,498. Fastening Scythes to Scythe-poles, W. P. Thompson.—(*C. F. L. Grabner, Germany*)
13,499. Decomposition of Alkali Salts, A. Sindin-Larsen, London.
13,500. Artists' Easels, A. Slocombe, London.
13,501. Metal Letters for Shop-signs, E. E. and C. F. Gloss, London.
13,502 Ladies' Veiling, A. A. Smith, London.
13,503. Holder for Dominoes, R. W. Hassom London.
13,504. Resiliency of Pneumatic Tyres, R. E. Phillips.—(*The Overman Wheel Company, United States*)
13,505. Crank Axles for Cycles, R. E. Phillips.—(*The Overman Wheel Company, United States.*)
13,506. Manufacture of Explosives, H. H. Lake.—(*Dynamite-Actien-Gesellschaft vormals A. Nobel and Co., Germany.*)
13,507. Tobacco Pipes, S. R. English, London.
13,508. Mouthpieces for Tobacco Pipes, S. R. English, London.
13,509. Coal Boxes, H. E. Newton, London.
13,510. Ships' Berths, E. Lawson and J. Harvey, London.
13,511. Furnace Grates, M. F. Mulready, London.
13,512. Axle Bearings of Tramway Trucks, A. H. Wallis, London.
13,513. Filters, J. N. Carey, London.
13,514. Railway Carriage Door Guard, C. W. Martindale and S. Handscombe, London.
13,515. Holder for Twine Thread, &c., J. N. Carey, London.
13,516. Printing, J. H. Corthésy, Richmond.
13,517. Pianos, H. Wagner, London.
13,518. Stone Crushing Apparatus, C. W. Thompson, London.
13,519 Cooking, &c., Stove, A. J. and A. A. Stonely, London.
13,520. Locking or Securing Cycles, E. Beebee, Birmingham.
13,521. Floor Clamping Apparatus, T. H. Wyatt, Birmingham.
13,522. Facilitating the Turning of Vehicles, H. Carmont, London.
13,523. Electric Arc Lamp Reflectors, C. Coerper, London.
13,524. Gas Engines, A Vermersch, London.
13,525. Sewing Machine Attachments, W. Ross, London.

*13th July*, 1894.

13,526. Cycle Driving Gear, P. L. Renouf and F. Westwood, Birmingham.
13,527. Construction of Washing Coppers, W. Smith, Crayford.
13,528. Brakes for Bath Chairs, &c., A. Squire, London.
13,529. Inlet and Outlet for Lavatories, W Matthews, Manchester.
13,530. Cycle Wheels, H. Montgomerie, Newcastle-on-Tyne.
13,531. Device for Catching Beetles, G. E. Winter, London.
13,532. Upright Piano Action, R. Burn.—(*F. E. Wood, United States*)
13,533. Cases for Holding Fishing Flies, T. F. Edgeworth, Bristol.
13,534. Securing Window Cords, A. E. Hacking and R. A. Hall, Nottingham.
13,535. Fishing-line Winder and Drier, H. Brooke, Liverpool.
13,536. Lubricators, C. Ankers, Leicester.
13,537. Lamps, J. T. M. Hircock and J. T. B. Bennett, Birmingham.
13,538. Metal Bath Casting Moulds, J. McAllister, Glasgow.
13,539. Cycle Cranks, G. Pirnie, Dundee.
13,540. Propelling Ships, J. M. Gorham and A. V. Gifkins, Westminster.
13,541. Couplings for Railway Vehicles, J. Fyfe, Glasgow.
13,542. Cuff Links, T. Morton, Birmingham.
13,543. Railway Carriage Windows, W. Purdon, Leeds.
13,544. Engine, J. W. Gall and J. Penn, Leicester.
13,545. Tobacco Pouches, S. I. Whitfield, Birmingham.
13,546. Controlling Gas or other Motors, P. Burt, Glasgow.
13,547. Locomotive Steam Boilers, F. W. Webb, Crewe.
13,548. Bleaching Fibres, K. T. Sutherland and G. Esdaile, Manchester.
13,549. Working Electric Tramways, C. Anderson, Leeds.
13,550. Working Electric Tramways, C. Anderson, Leeds.
13,551. Driving Apparatus for Velocipedes, J. W. Flavell, Birmingham.
13,552. Hooks, G. E. Hughes, Wolverhampton.
13,553. Fencing Jackets, W. Johnston, Co. Kildare.
13,554. Nails, C. Schmidt, London.
13,555. Clips for Wearing Apparel, H. B. Birnbaum, London.
13,556. Closing, &c., Windows, S. Hill and R. Hodges, London.
13,557. Coin-freed Apparatus, S. F. Cohen and H. Rowse, London.
13,558. Puncture-proof Tire Covers, C. F. Newman, London.
13,559. Oiling Apparatus, W. L. Wise.—(*J. H. Turner and J. M. McKnight*, ——.)
13,560. A New Musical Toy, L. C. Heyermans, London.
13,561. Manufacturing Infants' Boots, A. Cunnington, London.
13,562. Filters, A. Smith, London.
13,563. Music Stools, H. Brooks, London.
13,564. Attachments for Shirts, H. S. Cawthorn, London.
13,565. Manufacture of Cigarettes, A. G. Goodes, London.
13,566. Stencil Sheet Printing, J. Joseh, J. Fordham, and G. H. Smith, London.
13,567. Planimeters, W. F. Stanley and A. Amsler, London.
13,568. Electric Switch, F. and F. W. Tallack and L. Hendlé, London.
13,569. Railway Signalling Apparatus, J. Johns, London.
13,570. Apparatus for Weaving Carpets, I. Ginzkey, London.
13,571. Brooms for Washing Purposes, W. Fairclough, London.
13,572. Ladies' Shirt Fronts, &c., F. W. Mugford, London.
13,573. Book-mark, R. H. Campbell, London.
13,574. Drawing-off Liquids, F. H. Nalder, C. W. S. Crawley, and A. Soames, London.
13,575. Self-steering of Ships, &c., Nehmer Bros, London.
13,576. Sovereign Purse, C. and W. T. Smith, Birmingham.
13,577. Nitrosamines, J. Y. Johnson.—(*The Badische Anilin and Soda Fabrik, Germany.*)
13,578. Rotary Pumps and Turbines, O. Reynolds, London.
13,579. Coin-controlled Apparatus, J. O. Frost, London.
13,580. Window Curtains, W. P. Thompson.—(*A. Ockler, Germany.*)
13,581. Electric Cables, S. P. Thompson, Liverpool.
13,582. Mangling Machine, W. P. Thompson.—(*H. Dührkoop and A. Bogaske, Germany.*)
13,583. Shaping Machines, T. J. Wilkie, London.
13,584. Apparatus for Weaving Carpets, I. Ginzkey, London.
13,585. Cans, W. Pratt, London.
13,586. Steam Superheaters, J. Grouvelle and H. Arquembourg, London.
13,587. Vegetable Food, T. H. L. Bake and H. A. Leverett, London.
13,588. Hair Brushes, J. Knowles, London.
13,589. Manufacturing Bedstead Mounts, W. H. Bagley, London.
13,590. Clinical Thermometers, L. Peroni, London.
13,591. Cycle Tires, B. J. B. Mills.—(*P. B. Carante and J. Bocuze, France.*)
13,592. Stick for Carrying Umbrellas, &c., A. Bachmann, London.
13,593. Chimney Cowl, E. W. Lovegrove, London.
13,594. Electric Heating Apparatus, H. Helberger, London.
13,595. Files for Papers, E. Edwards.—(*W. Beller, Germany.*)

*14th July*, 1894.

13,596. Artificial Whalebone, J. P. O'Donnell.—(*J. A. Schweitzer, France.*)
13,597. Smoke Extractor, J. H. Ashworth and A. and W. Gillespie, Oldham.
13,598. Burners for Hydrocarbon Oils, W. H. Parker, Birmingham.
13,599. Finishing Woven Fabrics, J. Duxbury, Manchester.
13,600. Bobbins, H. W. Wilson, Manchester.
13,601. Golf Clubs, H. Fawsitt, Manchester.
13,602. Air-inflated Horse-collar, C. A. Garvie, Leith.
13,603. Finishing Velvets, J. and R. Dutton, Manchester.

13,604. Propulsion of Ships, E. J. Warmington, Southminster.
13,605. Wire Mails and Healds, J. A. Greenwood, Bradford.
13,606 Displaying Tickets on Boots, &c, W. Potter, London.
13,607. Wooden Blocks for Paving, R. Y. Ardagh, Birmingham.
13,608. Ejecting Mechanism of Small-arms, W. Baker, Birmingham.
13,609. Lamp-wick Winding Mechanism, W. T. Webber, Birmingham.
13,610. Jacquard Machines, A. Lockwood, Keighley.
13,611. Pipe Joints, E. Chrisfield, Milton-next-Sittingbourne.
13,612. Filters, A. Turnbull, Glasgow.
13,613. Hanging Garments, M. W. Frosch. —(*B. Walter, Germany.*)
13,614. Wrapping Card Fillets on Cylinders, F. G. Dransfield, Manchester.
13,615 Cooking, &c, Appliances, J. H. Ross, Birmingham.
13,616. Brush for Photographic Negatives, J. B. Brooks, Birmingham.
13,617. Syphon Cisterns, P. Hitchcock, Liverpool.
13,618. Looms, The Chlidema Company, Ld, and E. Burgham, Birmingham.
13,619 Combined Ruler and Rule, W. Evans, sen., Birmingham
13,620. Apparatus for Washing Rags, J. Joiner, London.
13,621. Machine for Scattering Manure, E. Scheiblich, London.
13,622. Wire Mattresses, W. McLaren and H. E. Brown, London.
13,623. Invisible Electric Switch, T. E. Waltham, London.
13,624. Dust Bins and the like, F. S. Salberg, London.
13,625. Window Sash Fasteners, G. W. Pollard, Liverpool.
13,626. Making Abraiding Covers, W. H. Staynes, London.
13,627. Preventing Bad Smells, F. A. Bates, Manchester.
13,628. Dry-hopping Apparatus, H. B. Hollis, London.
13,629. Manufacture of Sardine Boxes, E. R. Peltier, London.
13,630. Putting Matches in Frames, &c., F. Durant, London.
13,631. Carriage Harness, &c., C. H. Burgess, London.
13,632 Heating Apparatus, A. G. Bessemer, jun., London.
13,633. Roller Skates, C. J. Markey, London.
13,634. Arc Lamps, J. W. Rogers, London.
13,635. Machinery for Locomotives, A. E. Hodder and F. W. Matthews, London.
13,636. Transmitting Messages, &c., H. Whawell, London.
13,637. Registering Physiological Subjects, De B. Birch, London.
13,638. Apparatus for Walking, &c., J. Lewthwaite, London.
13,639. Shirt Collars, J. E. Jack, London.
13,640. Medico-electric Pad or Bandage, A. Owen, London.
13,641. System of Musical Notation, W. S. Seaton, London.
13,642. Hot-water Apparatus, F. B. Hill and R. D. Brett, London.
13,643. Heating Apparatus, L. Degache, London.
13,644. Machines for Writing in Cipher, R. Harte, London.
13,645. Manufacture of Barrels, E. Redman, London.
13,646. Manufacture of Barrels, E. Redman, London.

*16th July*, 1894.

13,647. Duplex Teapot, J. Crabtree, Lincoln.
13,648. Flying Apparatus, E. J. W. P. Birnbaum, London.
13,649. Movable Stretching Back, W. J. Irvine, Belfast.
13,650. Testing Fabrics, J. W. Fawcett and W. Shambrook, Huddersfield.
13,651. Treating Irons for Ironing, J. A. Holmes, Leeds.
13,652. Electric Switches, C. Esson, London.
13,653. Paper Testing Machines, G. O. Woolley, Gloucester.
13,654. Footstool and Fire-escape, R. Loescher, London.
13,655. Hand Circular Saw, J. W. and G. Cuffling and R. Hudson, Chesterfield.
13,656. Iron or Steel Roller Frames, J. Bousfield, York.
13,657. Pressure Gauge, J. R. Jackson and E. L. Mare, Manchester.
13,658 Cycle Saddle Securing, J. B. Brooks, Birmingham.
13,659. Press-drills for Attaching Ploughs, E. Bennett, Great Driffield.
13,660. Velocipedes, A. T. Andrews, Birmingham.
13,661. Toy Windmill, R. Wattleworth, M. A. Mason, and J. M. Brindle, Manchester.
13,662. Marine Governor, A. Wilson and W. Morrison, Hull.
13,663. Combination Cot Chair Bedstead, T. Pool, Birmingham.
13,664. Lamp Chimneys, J. and J. Hinks and Son, Birmingham.
13,665. Covers for Vessels, A. W. Montgomery-Moore, London.
13,666. Ventilating Railway Vehicles, B. H. Thwaite, London.
13,667. Candied Lemon and other Peel, C. Greenhalgh, Manchester.
13,668. Compressing and Sewing Jute, W. E. S. Garde, Accrington.
13,669. Railway Tickets, &c., F. A. Ludlow, Birmingham.
13,670. Elastic Tires for Wheels, &c, J. Tonks, Birmingham.
13,671. Binding Framework of Windows, R. Cussons, Bradford.
13,672. Extracting Suint from Wool, E. R. Lagerie Manchester.
13,673. Paper-marking Rollers, R. Brown, Glasgow.
13,674. Projectiles, H. V. Keeson, London.
13,675. Gas, Oil, and other Stoves, H. V. Rippingille London.
13,676. Negatives for Raised Type, W. Cordeaux, Yorks.
13,677. Extracting Potash from Grease, F. R. Lagerie, London.
13,678. Selvedge Motions for Looms, &c, J. Cork. London.
13,679. Portable Copying Press, &c., E. Smith, London.
13,680. Tablet Memorandum Case, &c., E. Smith, London.
13,681. Instructing Children in Colours, L. Smith, London.
13,682. Egg-cruet, M. Emanuel and A. Pappenheimer, London.
13,683. Chemical Extraction of Copper, J. P. Ploeg, London.
13,684. Lifting and Feeding Paper, A. Reisser, London.
13,685 Automatic Closing of Valves, B. Hannen, jun., London.
13,686. Preventing Bottle Accidents, G. Stubbs, Worthing.
13,687. Fastenings for Bracelet, J. W. Rohde, London.
13,688. Attaching Handles to Bowls, A. R. MacLean, London.
13,689. Syphon Waste Preventers, E. G. Highton, London.
13,690. Pendulum Clocks, B. J. B. Mills.—(*La Société Anonyme pour l'exploitation des Brevets Dardenne, Belgium.*)
13,691. Protecting Pastern Joints of Horses, J. Fabry, London.
13,692. Arrangements of Buildings, J. F. Spencer, London.
13,693. Hydraulic Lifts and Appliances, M. T. Medway, London.
13,694. Sewing Machines, P. A. Newton.—(*The Keats Maschinen Gesellschaft, Germany*)
13,695. Anthraquinone, O. Imray.—(*The Farbwerke vormals Meister, Lucius, and Brüning, Germany*)
13,696. Ensuring Safety on Railways, &c, E Tyer, London.
13,697. Sodium Persulphate Disinfectant, L. Lederer, London.
13,698. Armoured and other Hose, J. Thompson, London.
13,699. A New or Improved Fining Funnel, G. Porter, London.
13,700. Switch-board Mechanism, J. E. Kingsbury.—(*The Western Electric Company, United States*)
13,701. Spring Centres for Swing Doors, T. Pearl, London.
13,702. Ventilation for Public Buildings, W. Perry, Tottenham.
13,703. Apparatus for Printing Tickets, P. Reiner, London.
13,704. Automatic Delivery Machines, P. Reiner, London.
13,705. Jacquard Card Punch-selecting Machines, J. Hough, London.
13,706. Electric Light Shade, A. H. Entwistle, H. J. Stephens, and A. Dubber, London.
13,707. Cover for Velocipedes, B. Vichmann and C Pawlin, London.
13,708. Elastic Tires, C. K. Welch, London.
13,709. Forcing, &c., Liquid Substances, J. Taylor, London.
13,710. Generating Steam from Refuse, T. W. Baker, London.
13,711. Cigars, A. J. Boult.—(*A. Bollard, Canada*)
13,712. Sterilisation, &c, of Milk, R. G. Nash, London.
13,713. Air Propellers, J. D. Sutcliffe and W. Casmey, Manchester.
13,714. Blasting Charges in Mines, L. Jaroljmek, London.
13,715. Fastening for Cellar Flaps, E. G. Coumbe, London.

*17th July*, 1894.

13,716. Automatic Disinfector, C. G. Picking, London.
13,717. Turning Over Leaves of Music, F. S. Whittell, Huddersfield.
13,718. Game and Vermin Trap, C. E. P. Groth, London.
13,719. Wheels for Road Vehicles, J. Dakers, Aberdeen.
13,720. Tab for Braces, G. Buckley and F. Buckley, Halifax.
13,721. Manufacturing Fibrous Materials, T. Sloper, Devizes.
13,722. Producing Butter from Milk, S. H. Wright, Hereford.
13,723. Serving Rigging with Yarn, C. Searle, Stockton-on-Tees.
13,724. Twine Holders, A. Cole, Dublin.
13,725. Cycling Gear, W. P. Smith and E. Gear, London.
13,726. Belt Fastener, C. C. Walker, Walsall.
13,727. Connecting Warp to Warp Beams, G. D. Sykes, Halifax.
13,728. Pole for Overhead Wires, A. Dickinson, Darlaston.
13,729. Producing Designs or Surfaces, J. Scott, Glasgow.
13,730. Feeding Paper to Printing Machines, G. Duncan and T. W. T. Carran, Liverpool.
13,731. Turn-screw, W. Ward, Bristol.
13,732. Water-closet Apparatus, &c, J. Shanks, Glasgow.
13,733. Steam Boilers, A. Stirling, Glasgow.
13,734. India-rubber and Ink-eraser Case, M. Jeffery, Wombwell.
13,735. Driving Gear for Bicycles, F. L. Heeley, Birmingham.
13,736. Machine for Planing Wood, S. S. Hazeland, Cornwall.
13,737. Vehicles, A. Fehlen and The Princess Company, Ld., London.
13,738. Printing Blocks, F. I. Getty and National Chromatic Printing Company, Manchester.
13,739. Printing Blocks, F. I. Getty and National Chromatic Printing Company, Manchester.
13,740. Tubes for Feeding-bottles, &c., G. Raines, London.
13,741. Watch Glasses, E. Alawebb, London.
13,742. Medical Bags and Cases, &c., T. Bailey, London.
13,743. Wickless Safety Oil Lamp, J. Patterson, London.
13,744. Electro-magnetic Massage Roller, J. E. Spratt, London.
13,745. Fastening Boots and Shoes, J. Burgess, London.
13,746. Obtaining Power from Water, W. R. Bigsby-Chamberlin and W. M. Baker, London.
13,747. Electrical Coupling, W. H. Stevenson, London.
13,748. Machine-strap Fasteners, W. H. Chase, London.
13,749. Electric Signalling Apparatus, C. A. Allison.—(*The Standard Electric Signal Company, United States*)
13,750. Electric Signalling Apparatus, C. A. Allison.—(*The Standard Electric Signal Company, United States.*)
13,751. Electric Signalling Apparatus, C. A. Allison.—(*The Standard Electric Signal Company, United States.*)
13,752. Construction of Boxes and Cases, G. A. Farini, London.
13,753. Serving Boards, &c., W. Armstrong and A. H. Sansum, London.
13,754. Lamp for Advertising, G. C. Downing.—(*E. and L. Charlot, France*)
13,755. Zinco Plate Bevelling Machine, A. Shiner, London.
13,756. Electrolytic Cells, C. N. Waite, London.
13,757. Oil Cans, J. Schwiebert, Germany.
13,758. Apparatus for Manufacturing Gas, F. Mayer, London.
13,759. Machines for Filling Bottles, S. B. Smallwood, London.
13,760. Grain Driers, I. G. Hooper, London.
13,761. Regenerative and other Furnaces, S. M. Trapp, London.
13,762. Electric Railways, C. D. Jenney, London.
13,763. Brake Shoes, W. D. Sargent, London.
13,764. Handles of Golf Clubs, &c., C. H. Clarke, London.
13,765. Electric Railways, E. H. Johnson and R. Lundell, London.
13,766. Cash-registering Machines, J. J. Webster and C. H. Little, London.
13,767. Coin-freed Machines, G. A. Brachhausen and P. Riessner, London.
13,768. Displaying Advertisements, A. F. Bird, London.
13,769. Mechanical Musical Instruments, J. Schanz, London.
13,770. Shoulder Straps and the like, E. Rice, London.
13,771. Electric Railways, E. Lachmann, London.
13,772. Spinning Machinery, A. R. Erbslöh, London.
13,773. Parallel Rules, C. H. Beeler, jun., London.
13,774. Valve Gear, J. E. Wallis and Wallis and Steevens, Ld., London.
13,775. Manufacture of Boots and Shoes, D. Bryan, London.
13,776. Manufacture of Wheel Rims, C. S. Dikeman, London.
13,777. Purifying Effluent Waters, W. J. Pughsley, London.
13,778. Mimeograph Sheets for Copying, W. J. Peart, Birmingham.
13,779. Middlings Purifiers, R. Lund, London.
13,780. Carrying Military Accoutrements, W. S. Oliver, London.
13,781. Manufacture of Flanged Tubes, H. Howard, London.
13,782 Water-closets, S. Jennings and J. Morley, London.
13,783. Presses, O. W. Ketchum London
13,784. Twisting Machines, G. L. Brownell, London.
13,785. Pens, W. C. Hawtin, London.
13,786. Pneumatic Tires, G. Pickhardt, London.
13,787. Fire-arms, A. J. Boult.—(*P. B. Latrige France*)
13,788 Steam Engines, W. P. Thompson.—(*E. Gschwind, United States.*)
13,789. Boiler and Steam-pipe Covering, J. Douglas-Foulis, Liverpool.
13,790. Process for Making Paper Boards, W. N. Cornell, Leeds.
13,791. Electric Lamps, W. L. W. Williams and G. H. Morgan, Liverpool.
13,792 Water Heaters, W. P. Thompson —(*A. H, F. J., and H. S. Humphrey, ———.*)
13,793. Velocipede Bearings, J. F and D. H. Lewin, London.
13,794. Electric Conduits, &c., J. W. Eisenhuth, R. Herman, and E. M. Herman, Liverpool.
13,795. Electro-plating, W. P. Thompson.—(*C. M. Barber, United States*)
13,796. Balancing Devices, &c, H. P. Lavender, London.
13,797. Moulds for Casting Glass Balls, J. Slaytor, London.
13,798. Preservation of Photographs, &c., A. H. Church and W. S. Simpson, London.
13,799. Wheels for Cycles, W. Gilliam, London.
13,800. Hot-water Apparatus, D. J. Ross, London.
13,801. Tipping Gear for Road Wagons, C. Davis, London.

*18th July*, 1894.

13,802. Locking the Triggers of Fire arms, C E. and J. W. Batcock, London.
13,803. Automatic Nosing Motion, &c, L. Rushworth, Manchester.
13,804. Connecting Metal, &c, Pipes, T. Robinson, Lancashire.
13,805. A Game, J. M Porter and A. Mitchell, Leeds.
13,806. Chimney and Ventilator Hood, E. W. Astle and C. E. Terry-Terry, Derby.
13,807. Cooling Beer, &c., J. Scouller, Glasgow.
13,808. Beaded Fabrics, J. A. C. Leistner, Manchester.
13,809. Bearings for Spinning Spindles, A. Hitchon, Accrington.
13,810 Reversible Window Sashes, E. G. Kendall, Staffordshire.
13,811. Pneumatic Tires and Pumps, P. A. F. Pratt, London.
13,812. Blowers, T. Duncan, Oldham.
13,813. Brick-making Machinery, W. Wilkinson and H. Alexander, Leeds.
13,814. Brick and Tile Presses, W. Wilkinson and H. Alexander, Leeds.
13,815. Pirn-winding Machines, W. Whiteley, Halifax.
13,816. Securing Pneumatic Tires to Cycle Rims, T. Guthrie and W. T. Hall, Newcastle-on-Tyne.
13,817. Securing Studs to Garments, J. Walker, Birmingham.
13,818. A Motor, H. Tee, Liverpool.
13,819. Anchor, H. O. Dunn, Liverpool.
13,820. Air-heating Apparatus, J. A. Wade, Liverpool.
13,821. Expanding Pulleys, R. Pippette, London.
13,822. Cask Tilter, J. H. and W. F. Filbee, Birmingham.
13,823. New Compound, O. Thiele, Liverpool.
13,824. Bag Locks, J. B. Brooks, Birmingham.
13,825. Caloric Engines, W. Arschauloff, Glasgow.
13,826. Uniting the Frames of Velocipedes, W. F. Taylor and G. J. Philpott, Croydon.
13,827. Kitchener, W. E. Fox, Eastbourne.
13,828. Rim for Lawn Tennis Racket, C. Burrows, Workington.
13,829. Boxes for Carrying Hats, C. Blyth, Manchester.
13,830. Flexible Pipe Couplings and Clips, J. Kippax, London.
13,831. Appliances for Preventing Sea-sickness, M. Runkel, London.
13,832. Brace or Suspender Buckle, J. S. Römpler, London.
13,833. Self-acting Tongued Harp, E. Lamprell, Northamptonshire.
13,834. Protecting Clothing, J. Nadler and R. Merkelt, London.
13,835. Nicotine Trap Pipe, F. Watts and R. W. Shepherd, London.
13,836 Apparatus for Collecting Gases, C. J. Yarnold, London.
13,837. Cycle Gears, S. G. Tripp and S. J. Clay, London.
13,838. Artificial Cork Manufacture, G. Hagemann, London.
13,839. Expanding Lock, M. H. Newtoh, London.
13,840. Double-action Safety Valve, G. W. Linford, London.
13,841. Gas Making Retorts, A. Scott and P. McLean, Galashiels.
13,842. Pistons, E. E. Wigzell, London.

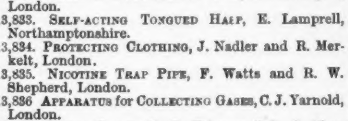
## SELECTED AMERICAN PATENTS.

*From the United States Patent Office Official Gazette.*

**516,014.** Mortising Machine, *D. Hepp, Chicago, Ill. —Filed November 28th, 1893.*

*Claim.*—(1) A mortising machine, comprising a central bit, side bits geared to the central bit and of less length than the said central bit, and hollow chisels incasing the side bits, substantially as described. (2) A mortising machine, comprising a central bit, side bits geared with the central bit and provided with extensions of less diameter, said side bits being of less length than the central bit, and hollow chisels incasing the large portion of the side bits, substantially as described. (3) In a mortising machine, the combination with a bearing box, a central bit mounted in the box and provided with a gear wheel, side bits, shafts mounted in the box and provided with gear wheels meshing with the gear wheel of the central bit, and bits carried by the said side shafts, of hollow chisels secured to the box and inclosing the said side bits, the said chisels being apertured, substantially as described.

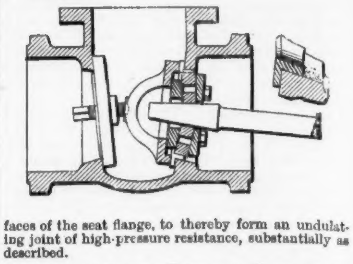
516,014



**516,658.** Process of Seating Valve Bodies, *F. H. Richards, Hartford, Conn.—Filed July 11th, 1892.*

*Claim.*—The herein-described process of seating valves, which consists in casting the valve body with an annular undercut seat flange having rough or unfinished surfaces, making a seat blank with a seat ring and anchorage flange having rough or unfinished surfaces, applying the seat blank with the seat ring resting upon the seat face of the seat flange and with the anchorage flange projecting below said seat face, and simultaneously pressing the seat ring to its bearing and internally rolling the anchorage flange outward on lines at an inclination to the plane of the seat ring, and at the same time bedding the roughened faces of the seat blank into the roughened faces of the seat flange, to thereby form an undulating joint of high-pressure resistance, substantially as described.

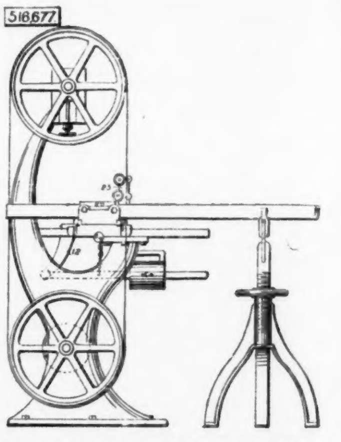
516,658



**516,677.** Automatic Feed for Band Sawing Machines, *F. E. Cross, Waterbury, Conn.—Filed May 15th, 1893.*

*Claim.*—(1) A feeding attachment for band sawing machines consisting of a frame 17 having an opening, a carriage provided with fixed and movable jaws adapted to travel in said opening, suitable means for adjustably securing the frame in place, and suitable means for moving the carriage forward. (2) A feeding attachment for band sawing machines consisting of a frame having a standard extending upward therefrom, an arm 25 adjustably secured to the standard and guide rollers on the arm between which the saw runs, a carriage adapted to travel in the frame, suitable means for moving the carriage forward, and a clamp, bolt, and set screw by which the frame and carriage may be adjusted at different angles to the normal plane of the saw, the operative portion of the saw being at the same time twisted into a plane at right angles to the plane of the carriage. (3) A feeding attachment for band sawing machines consisting of a frame having an opening 16, suitable means for securing the frame in position, a carriage for the bar to be operated upon adapted to travel in said opening, a bracket 10 having a pulley 9 and an arm 12, a lever pivoted to said arm and carrying an adjustable weight, and a chain passing over said pulley and connected to the carriage and lever. (4) In a band sawing machine the combination with the table, saw, and standard, of a movable carriage for the bar to be operated upon, suitable means for adjusting the line of travel of the carriage at different angles to the normal plane of the saw and for twisting the operative portion of the saw into a plane at right angles to the line of travel of the carriage, a carrier B having rollers 35 for supporting the outer end of the bar, a support 34 having stops 36 upon which the carrier travels, a suitable stand for said support, and suitable means for raising and lowering the support on the standard.

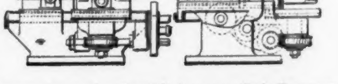
516677



**516,678.** Slide Rest for Lathes, *H. Eckhardt, Dortmund, Germany.—Filed May 11th, 1892.*

*Claim.*—(1) In a tool rest slide, the combination of the main frame, two or more slides mounted and adapted to slide thereon, a screw for moving the slides to and from each other and connections from said screw to the cam for moving the slide transversely to the screw, substantially as described. (2) In a tool rest slide, the combination of a main frame, slides mounted and adapted to slide thereon, seats for the cutting tools adapted to slide on the slides, means for moving the slides to and from each other, and cams to slide the tool seats independently of each other, substantially as described.

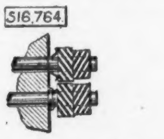
516,678



**516,764.** Apparatus for Forging Screws by Rolling, *C. Fairbairn and M. Wells, Manchester, England.—Filed July 28th, 1893.*

*Claim.*—(1) In screwing machines in which the screws are forged between rotary grooved rollers, and in which the grooves are formed upon the peripheries of the rollers, a roller divided transversely into two or more parts, of which the front part only is fixed upon the roller spindle, substantially as and for the purpose hereinbefore described, and as illustrated by the accompanying drawings. (2) In screwing machines in which the screws are forged between rotary grooved rollers, and in which the grooves are formed upon the peripheries of the rollers, the combination with transversely divided rollers, the front portion of which alone is fixed upon the spindle, of a spring tending to resist the longitudinal motion of the back portion or portions of the roller, substantially as hereinbefore described, and as illustrated by the accompanying drawings.

516,764



## INTERNATIONAL NAVIGATION CONGRESS.

(*By our Special Commissioner.*)

The sixth Congress has been occupied during the past week in considering the papers which have been sent in. Nearly five hundred members out of the total number of subscribers have put in an appearance. Only a very small proportion of the large number of Americans who were guaranteed as members have attended at the Hague.

The first section has been occupied chiefly with matters relating to the construction and maintenance of canals and navigable waterways, under the presidency of M. Van Bosse. The second section, of which M. Van Zuylen is president, has been occupied with papers relating to stoppages on waterways in winter from ice, and the best means of preventing them. The third section, over which M. Deking Dura is president, has dealt with tolls on navigable waterways; and the fourth section, of which M. Van Diesen is president, has dealt with tidal waterways, and the relation which exists between the curves in channels and the depth and width.

On Monday the members of the Congress were received by the Minister of the Waterstaat, and on Wednesday by the Municipality of the Hague, at the Town Hall. On Thursday evening an official dinner took place at Schevingen.

On Monday there was an excursion to Rotterdam and the Hook of Holland, in which more than four hundred members were present. The party left the Hague by train at 7.30 a.m., and went to the new station at the Hook of Holland, where they embarked on a steamer, and were taken a short way down the river to look at the jetties which train the river into the North Sea. On the way the Amsterdam, the last new steamboat put on the Harwich line by the Great Eastern Railway Company, was passed. The party were then taken up the river to Rotterdam and through the harbour, all the ships and barges lying there being dressed with flags for the occasion. The new iron bascule bridge was opened, and the boat steamed through into the Deephaven and back again. The party then landed, and were entertained with lavish hospitality at luncheon by the city of Rotterdam; after which they proceeded in a long procession of carriages through all the principal streets of the town, back to the steamboat, and then up the Maas to Gorinchen; here the lock on the new Merwede Canal was inspected. It is a very fine piece of work, and varies from most structures of the kind in having a double set of gates at each end, each pair of gates pointing different ways, so as to be adaptable to the condition of the water on whichever side, a flood in the river might be the highest. In passing up the river an object lesson was given which, if only the British workman had the sense to see it, would show him the harm that is being done to England by strikes and high wages. At a shipbuilding yard on the banks of the river was to be seen the dredger which is being built for the River Wear Commissioners, the contract for which was placed in Holland, because owing to the lower rate of wages it could be supplied at a price several thousand pounds below the lowest tender that could be obtained in England. After being received by the authorities at Gorinchen, the party proceeded by train to Dordrecht, where they were entertained at dinner by the town authorities. The arrival at the Hague was not accomplished till midnight. The following particulars of the port of Rotterdam are taken from the paper contributed to the Congress, and read on the previous day by M. De Jongh, Director of Public Works, and the paper of Mr. W. Gustav Triest, of New York.

### THE PORT OF ROTTERDAM.

The Netherlands owe their development and prosperity principally to their geographical position. Situated between the countries bordering on the Baltic and those of Southern Europe, and at the mouth of a river which penetrates to the very heart of the Continent, they were in the Middle Ages the most important market of the world. Bruges, Ghent, Antwerp, were at that time the great meeting-places for merchants from all countries. Spanish and Portuguese ships brought to these cities the varied merchandise of the South of Europe and the Indies, and the products of Russia and the countries of the North found their way thither by the navigation of the Baltic, as well as by the Rhine and Moselle.

Rotterdam at one time was but a fishing village. The discovery of the art of salting and packing herrings in barrels, so that they could be exported, opened a new era to the Netherlands. In 1562 the number of boats, called buses, engaged in conveying the salted fish to other countries, was estimated at 700, and the merchant vessels nearly 1000. The Dutch at that time had acquired the pre-eminence at sea. In Elizabeth's reign the two provinces of Holland and Zealand possessed more vessels and seamen than the whole of Great Britain. By the help of their ships the Dutch were able to hold their own against the Spaniards, and while commerce forsook Antwerp and the Belgian cities, the trade of Holland was regularly maintained in the Spanish and Portuguese ports, and the Dutch traders sent there grain and timber, and even munitions of war. Owing to the seizure of Dutch ships in Spanish ports, and the Dutch being hindered from buying the produce of India in the markets of Spain, they resolved to go in search of it in the land of its production, and thus laid the foundation in the East Indies of the opulent colonial empire, and of the establishment of the Dutch East India Company, which paid an average dividend for several years of 35 per cent., and in which 20,000 persons were interested. Thus was shown the remarkable fact in the seventeenth century of a small strip of land which, with enormous labour, had been rescued from the sea, and with great difficulty was maintained in safety, making war upon—at that time—the most formidable kingdom of the world, who had the disposal of the treasures of both the Indies, and seizing from Spain her monopoly. This small country of Holland was then overflowing with merchandise which she did not produce, growing very little corn. Yet no country in the world had its granaries more richly supplied; growing little or no flax, yet largely engaged in weaving; with small flocks or herds, still abounding in woollens and cloths; with no vineyards, yet affording a market for wine from Germany and France; with no forests, yet building more ships than all the rest of the continent. This prosperity was reflected in the extension of her harbour and shipping accommodation. At the beginning of the 17th century Rotterdam could boast of eight docks, some of them over 200ft. in width. After this, the navigation of the port received a check, and it was only towards the middle of the present century, when steam navigation was established, that it became necessary to develope the works of the port. Between 1850-60 the Boompjes were provided with quays of masonry, and several wharves were built along the river. The dredging of the Voorne and Putten Canal, in 1820-27, rendered Rotterdam accessible at high water to vessels drawing 18ft., but the locks did not admit of the passage of larger vessels than 155ft. in length and 45ft. beam. In 1863 it was decided by the Government to open out a new mouth to the river Maas by cutting through the sand dunes at the Hook of Holland. The navigable depth of water up to Rotterdam was increased from 13·88ft. at high water in 1875, to 31·65ft. in 1893, the rise of tide being 5¼ft. The number of vessels in the meantime has increased from 1970, with 393,393 tons burden, in 1850, to 4770 ships, with 3,614,654 tons burden, being an increase of 80 per cent. in the tonnage of the maritime shipping; while at the same time the inland shipping has increased 75½ per cent.

The method of carrying on the shipping trade has entirely altered since the introduction of steam. Formerly, after a voyage to the Indies, the vessel lay up very much at her ease, and it was only after several months that her cargo was disposed of and she again put to sea. Navigation was then very profitable, and often in two or three voyages the profits were sufficient to pay for the building of the ship. Now, despatch in the loading and unloading of steam vessels is one of the first essentials of a port, and the machinery and equipment necessary for this purpose must be provided. For this purpose a large number of steam and also hydraulic cranes have been fixed on the quays, and coal-tips on Sir William Armstrong's plan provided. An experiment made in the use of electricity for working the cranes was so satisfactory that this system is to be extended. The electricity is obtained from the Tower electric light station. A contract has been entered into for the supply of six cranes, costing £920 each, warranted by the makers to run at 315 watts while engaged in the following work:—A load of 1500 kilos. deposited on the quay to be lifted to the maximum height, lowered 48½ft., then replaced on the quay on the other side of the crane. It is anticipated that the power which by the descent of the load will be returned to the cable, will reduce the consumption to 240 watts. The electricity is to be produced for this work under a tension of 700 volts in a continuous current, and first directed to two accumulator stations, one on each side of the harbour, whence it will be divided upon the system of five conductors. The cranes work with a tension of 440 volts. The engines will be always ready to work, and only use electricity when lifting or turning round. Upon the descent a certain quantity of the electricity will be returned to the system, the motors then revolving in opposite directions.

The development of the inland navigation has had to be taken into account in the plans for the enlargement of the works of the port. The sea-going vessels which have to tranship their cargo into the boats of the Rhine are not moored at the quays, but in the middle of the harbour, so that the barges can lie on both sides. For this purpose moorings have been laid down for twenty ships. The construction of the Riju haven and of the Katendrecht docks has been designed with the same object, the width reaching over 1300ft.

The paper of Gustav Triest dealt principally with the construction of the new waterway from the Hook of Holland to Rotterdam.

Four papers were contributed on the "Means of Preventing Stoppages on Canals by Ice," by M. Camerée and M. Rigaux, engineers of the Ponts et Chaussées, respectively at Paris and Charleville; and by M. Bekaar and Nelemans, engineers of the Waterstaat in Holland. The importance of this subject may be inferred from the fact that during the winter of 1890-91 the interruption of the navigation of the Seine by ice continued for forty-three days from the 14th of December to the 26th of January. On the Seine near Surenes, above Rouen, one large ice bank extended over a length of about half a mile, by a width of 350ft., and was composed of a layer of strong ice, varying from 6in. to 10in. in thickness, from under which pieces emerged on the up-stream side at an angle of 30 deg., forming projections 2ft. thick, and below this layer the thickness was increased by a mass of fragments frozen together, and mingled with a quantity of rotten ice. In order to get rid of this block, which by stopping the flow of the ice from up stream had become dangerous to a railway bridge, recourse was had to the simultaneous use of ice-breaking boats and blasting. A channel was first made along the side on which the ice was thinnest by a boat protected by iron sheeting, which was hauled by four horses, a rolling motion being given by twelve men on board. When their passage was opened out, holes were dug in a line parallel with it, by means of pickaxes, to a depth of 15in., and at distances apart of 9ft. to 10ft. In these were placed charges composed of cartridges of melinite connected together by fuses united by a single fuse ending in a Bickford match. With this main line of fuses transverse lines at about 100ft. apart were connected. The charges were covered with broken ice by way of tamping. After the discharge, blocks from 900ft. to 1000ft. long, and 40ft. to 50ft. wide, were detached from the ice bank, which were sufficiently small to allow of their passing through the opening of the bridge, their progress being assisted by a tug boat protected by iron plates.

Where the ice was less densely packed, single cartridges placed at intervals of about 10ft., in holes about 5in. deep, were found sufficient to break up the mass. By this operation the bank was broken up and the channel opened in one day. Other blocks were dealt with in the same way, and a total length of 2·66 miles was cleared by a week's work, at a cost, including the explosives, of £600—equal to 31·75 pence per yard lineal.

Before the general breaking-up of the ice, the whole bank which covered the basin above the locks of Bougival over an area of about 6000 square yards was dislodged by a gang of workmen in a boat, a steam-tug boat, and cartridges laid on the surface. The melinite cartridges, containing from 100 to 135 grains, were attached, at intervals of 3ft. apart, to wooden rods 13ft. long, and joined together so as to form lines from 160ft. in length, and laid in grooves cut with pickaxes, filled with snow and ice. By this means a channel about 10ft. wide was opened in a coating of strong ice, from 6in. to 1ft. in thickness. The detached blocks were then broken up by the boat and by men with axes. During the explosion several windows were broken in the houses, at a distance of 650ft. This plan was therefore abandoned, and the following substituted:—In the middle of the channel to be opened holes were bored every 16ft., through which charges composed of five cartridges were let down below the ice, and fired by a Bickford match. The explosion of these cartridges formed holes 10ft. to 12ft. in diameter, which remained separated by strips of dislodged ice, which the workmen demolished with axes. Above the Dam or Marly the ice was dislodged by the use of saws, worked by two men in cuts 13ft. apart, the pieces sawn through being broken up by axes. A trench 13ft. wide and 2354ft. long was made in a day and a-half by twenty workmen, and cost about 5 cents a lineal yard, including the purchase and hire of materials. The use of dynamite placed on the surface has been tried, but not found to answer.

Several other examples of ice breaking are given, but the above gives a sufficient representation of the methods adopted. The second paper dealt chiefly with the method of breaking ice by means of boats having their bows protected by strong wooden frames cased with sheet iron. The boat, being weighted in the stern, is drawn along by from ten to fifteen horses going at a trot and run at the ice, so that the stem rises on it and breaks it down, a rolling motion at the same time being given by the men in the boat. This method is not adapted for ice of more than 6in. thick. The ice breakers attached to the boat cost from £6 to £30.

The paper by Messrs. Bekaar and Nelemans deals with the means taken to break up the ice on the North Sea Canal and the Tiernenzen Ship Canal. Between 1828 and 1891 there were twelve winters in Holland when the ice was sufficiently thick to stop navigation, the temperatures on these occasions varying from 2 deg. to 11 deg. Fah. On the North Sea Canal a company was formed in 1879 for the purpose of keeping the waterway free from ice. They had constructed an ice breaker, which was attached by chains to one or more tug-boats. This ice breaker was 45¼ft. wide, having at its stern a cavity to receive the bow of the tug-boat, its total length being 64½ft., and the height varying from 6in. at the stem to 7·84ft. at stern. The weight was 82½ tons, and cost £2190. The results obtained were satisfactory in ordinary winters, when the thickness of the ice did not exceed 8in. For a thickness of from 4in. to 8in., two tugs of 50-horse power were required. The expenses mounted up to as much as £37 a day. A charge of 3d. per ton was levied on vessels navigating the canal from November to March, to cover the cost. This company was dissolved, as it was found that when the frost was severe this method did not answer, the ice in the winter of 1890-91 reaching nearly to 1·86ft. in thickness. During this winter attempts have been made to open a channel by cutting through the ice by hand labour, and dispersing the pieces thus broken by a steamer. Subsequently two torpedo boats were sent by the Government to break the ice by means of explosives. Charges of powder of from 8 lb. to 20 lb. were placed from 3½ft. to 4ft. below the ice at distances of about 35ft.; the holes made by the explosion were 13ft. to 30ft. in diameter. Altogether 838 charges were exploded, using 11,057 lb. of powder. The company spent in the winter of 1890-91 £3750. Subsequently another company was formed which had constructed two special ice-breaking boats, of which the larger is 139ft. long, and 35ft. beam, having engines of 830-horse power, and costing £15,950; and the other 103ft. long, 27½ft. beam, with engines of 350-horse power, and costing £6800. The keels have an inclination so that the stern of the boat may run on to the ice and break it down. The expense of working the larger boat is reckoned at £11 10s. a day, and of the smaller £7 10s. Since the construction of these boats the winters have not been sufficiently severe to test their efficiency in breaking the ice where it is very thick.

On the Tiernenzen Canal the passage of the waterway was to a certain extent kept open by the steamers going to and from Ghent. Of these the Ouse, running between that port and Goole, did most service, and when other boats refused to run, went down the canal and opened out a passage in "a splendid way." Leaving Ghent at 7 a.m., she reached Tiernenzen at 5 p.m., the distance being 21 miles. The cargo had been stowed so as to make the steamer down at the stern by 1ft. When the ice resisted the progress of the steamer it glided slowly on to it, and broke it down by the weight.

In ordinary winters it has been found that the constant passage of the steamers up and down the canal has been found sufficient to prevent the ice forming to any thickness and to keep the waterway open.

The Sixth Congress was brought to a close on Saturday, the 28th ult., by a general meeting of all the members present, when it was decided, after a discussion, by a large majority, that the two congresses of interior and maritime navigation, which hitherto have been separate, and met at different times, should be united, and that in future the title should be simply the International Navigation Congress. It was also decided to form a permanent organisation having a representative for each country, from whom information as to the proceedings may be obtained, and to whom communications could be addressed. The necessity for this, if the Congress is to be permanent and representative, is obvious. As regards the Congress which has just terminated, it was impossible in England to obtain information at a period sufficiently early to be of service as to when and where the Congress was to be held, or as to the nature of the proposed subjects to be discussed; consequently there was not a single paper contributed by English engineers, and very few were present.

Invitations were read at the meeting from the representatives of Italy and Portugal inviting the Congress to meet at one of those places, and it was decided that the meeting in 1896 should take place in Italy.

## INSTITUTION OF MECHANICAL ENGINEERS.

### MANCHESTER SUMMER MEETING.

The summer meeting of the Institution of Mechanical Engineers, which is being held this week in Manchester, has proved the most successful gathering of the kind that has been held for a number of years past, nearly five hundred members intimating their intention of taking part in the proceedings, and there has not been so numerous an attendance since the London meeting in 1886. No doubt the exceptional interest attaching to Manchester as the centre of one of the most important engineering districts in the kingdom has been a great attraction, and certainly a programme of visits to engineering and other works in the immediate neighbourhood was provided which would much more than completely occupy the whole of the time the members had at their disposal.

The proceedings were formally opened on Tuesday morning with a reception of the President, Professor Alexander B. W. Kennedy, LL.D., F.R.S., and the Council and members of the Institution, in the Owens College, by Mr. Alderman Joseph Thompson, the Chairman of the Council of the Owens College, who acted as deputy for the Lord Mayor of Manchester, who had been unavoidably prevented from carrying out his original intention of being present to receive the President and members, and by Alderman Sir Wm. H. Bailey, the Mayor of Salford.

Alderman Thompson having explained that he had been requested by the Lord Mayor of Manchester to act on his behalf in receiving the members, said it gave him the greatest pleasure to extend to them a very cordial welcome to the city, and by virtue of the official power given to him by the Council of the Owens College, he bade them a cordial welcome to that building and to its use during their meetings. With regard to the Institution of Mechanical Engineers, although the study of their special branch of science did not go back to the beginning of things, its history spoke of times upon which memory fondly lingered. He thought it was not too much to say that the work which tended to make life happy was that which came from such societies as their own, which bridged their rivers, and made their streams, which gave them ease of locomotion and safety. This was the work which was entrusted to them, and they would receive their reward for it. He thought it peculiarly fitting that they should meet in the Owens College, where they taught not only the theory, but, to some extent, the practice of mechanical engineering. Then they knew that their branch of science was associated with various separate forms of training; the engineer must be a mathematician, and this they taught in the college, both applied and pure mathematics; the engineer must also be a chemist, and know something of the composition and mixture of his metals, and with regard to this branch of science, he must not forget to tell them that in the very hall in which they were assembled, the teaching of Roscoe, Schorlemmer, Thorpe, and others, in the past, and of Dixon and Dawkins at the present, had been heard. Engineering was also allied to electricity, and in the Owens College they had Professor Schaffer, as electrician, holding crowded classes. He repeated his words of welcome, in the name of the Corporation of Manchester, and on behalf of the Council of Owens College.

Sir Wm. H. Bailey (Mayor of Salford) welcomed the Society on behalf of the borough he represented. As Mayor of Salford, "the little borough across the stream," it was, he said, his duty to welcome the members of the Institution to the district, and he thought it would be difficult for them to find a place which possessed more interest to mechanical engineers than the district they were now visiting. Whether they looked at the historical development of mechanical tools, or even of the modern locomotive, they would find that the inventors of the district had exercised a remarkable influence. He would mention the names of Nasmyth, Whitworth, and Joule (who was born in Salford) as amongst the local inventors who had done service to engineering. The most successful engineers of the present were those who were well acquainted with the doings of the engineers of the past, and it was only by the study of the failures of those who had gone before that they could achieve success. In conclusion he joined with Mr. Thompson in giving them a cordial welcome to the district of Manchester and Salford, and they would, he must assure them, do their best to make their visit both pleasant and profitable.

The President—Professor Kennedy—thanked Alderman Thompson and Sir William Bailey on behalf of the Institution for their welcome to the city. It gave them great pleasure to meet in Manchester, which was, perhaps, the most interesting city in the country from the Society's point of view, and it was therefore extremely gratifying to be welcomed so heartily by the municipal and academic authorities.

The Secretary then read a paper by Dr. John Hopkinson, F.R.S.,

### On New Electric Lighting Works, Manchester.

The system adopted is a direct continuous current, with five conductors supplying consumers at a pressure of 100 volts, the total pressure between the outer conductors being 400 volts. The conductors are partly bare copper in concrete culverts, and partly india-rubber insulated cables in cast iron pipes. The arrangement of conductors is very similar to that which has been adopted in many other places, but is here carried out on a somewhat more extensive scale, the Portland-street culvert containing a total area of copper of 9¾ square inches. It will be observed that the sectional area of the three intermediate conductors is small, only ¼ square inch for each; whereas the total sectional area of the outer conductors in this case is no less than 4½ square inches. As might naturally be expected, such small intermediate conductors are in themselves inadequate to effect a perfect balance; the balance is therefore perfected by means of motor-generator machines fixed in outlying parts of the system. Each of these machines is wound with two circuits, so that the pair contains four circuits, each circuit being connected with two conductors of the five-wire system. The two machines being connected mechanically with each other by a coupling, any excess of current demanded from one section will be supplied by the circuit connected thereto, and the power required to effect this supply will be derived from one or more of the other circuits. As a compensating device this arrangement is found to work perfectly; it does not claim any originality, as it has been in use for some time in many places. Electricity can be supplied to customers at four different pressures, according to their requirements.

The system of bare conductors has the disadvantage that the general insulation is poor; but this really causes no trouble, as it is a general small leak over the whole system, and does not tend to get worse. There is one curious fact in connection with this defective insulation—the insulation of the positive conductor is always good, while that of the negative is always bad. The fact has been generally known for some time, but the author did not realise its importance till he experienced it. Electrolysis will deposit upon the negative conductor hydrogen from the moisture on the insulators; hence, this exceptionally defective insulation is not calculated to injure the conductor. The explanation, so far as the author is aware, was not known. The difference in insulation between the positive and negative conductors arises from electric osmosis, which may be explained as follows:—Suppose two vessels containing water to communicate by a cotton wick, and two electrodes differing much in potential to dip into the two vessels; then it is found that water passes over continuously from the vessel into which the positive electrode dips to that into which the negative electrode dips. This fact has long been known to physicists as a laboratory experiment. Next suppose two electrodes to be carried on porcelain insulators which dip into water, and the water to be maintained at earth potential, and the two electrodes to be one positive and the other negative; then, if the current leaking from each electrode into the water be measured, it is found that the leak from the negative is many times the leak from the positive. This experiment the author has himself tried. The action of bare conductors is the same upon a large scale. The main source for moisture is from the walls and floor of the culvert; this moisture will constantly creep over the porcelain insulators towards the negative conductor, but will creep away from the positive conductor, drying the neighbourhood of the latter and improving its insulation. With the five-wire system the troubles have been few, and all easily met; with the bare conductors there have been no troubles at all.

In the first instance, six engines and six dynamos of about 100-horse power each were put up, and also four engines and four dynamos of 400-horse power each. The six smaller dynamos give nearly 600 ampères at a little over 100 volts; the four larger give 600 ampères at a little over 100 volts. The engines are all vertical compound condensing, and drive their respective dynamos by link belts carried under jockey pulleys. The jockey pulleys work in every respect as well as simple belts of adequate length; and the loss of power is increased to only a very small extent, if at all. Compared with ordinary belt driving the saving in space is considerable. In comparison with high-speed direct driving, there is the advantage of entire freedom as to speed, both of engines and of dynamos; and there is less liability to vibration. On the other hand high-speed engines take less space, and the author thinks if single acting they make less noise. In his opinion there is no great balance of advantage in one system over the other. The condensers are ejector condensers, the condensing water being lifted some 30ft. in order to give an adequate head. These condensers have been found effective, giving a vacuum of 25in.; and they prove most convenient. The regulation of electric pressure is effected by adjustment of the governor whilst running. Two more engines and dynamos of 400-horse power, exactly like those already erected, have been ordered after the experience of last winter.

The boilers are of Lancashire type, 30ft. long and 8ft. diameter; at present they are six in number, and a seventh is now being added. They work at a pressure of 125 lb. per square inch, and are fitted with mechanical stokers, and the water is heated by economisers. The steam-pipes, feed-pipes, valves, and economisers are all in duplicate. The boiler-house, 77ft. long by 70ft. wide, is covered from end to end by a steel water tank weighing about 160 tons, constructed in seven compartments, and holding 205,000 gallons of water.

In addition to the engines already on order, there is room for eight more large engines and five additional boilers. Hitherto no accumulators have been used; but, in the author's opinion, the present reduced price of these, and their increased durability, justify their introduction into large stations as well as small. There will, of course, be no difficulty in adding them when it is desired.

There are connected to the mains 18,600 incandescent lamps of 16-candle power, 250 arc lamps, and motors to the extent of 16-horse power. This is an encouraging result when it is remembered that a preliminary supply on the two-wire system was begun only just a year ago. The average price to the consumer up to March 31st was about 5½d. per unit.

Mr. Alderman Higginbottom, at the request of the President, added a few further particulars. When the works were first laid out they were intended to supply the demand in Manchester for at least three years; but after five months' working the whole power laid down was virtually taken up, and they had to make a large extension for the next winter. Commercially, the results had been satisfactory, as they had close upon £5000 revenue on the five months' working, and he contemplated they would this year have £25,000 revenue.

Mr. Parker said he should like to know something more about the motor generators. When he had applied them—at Chelsea, Crystal Palace, and Oxford—they had done good work, but the manner of application was different from that followed in Manchester by Dr. Hopkinson. At first sight it appeared to him that by their method of application in Manchester, they would prove inefficient, and he would therefore like some particulars as to their behaviour.

Mr. Charles Hopkinson, in reply to a request for some particulars as to the buildings of the installation, said their arrangement was very simple, the plant was easy to keep clean, and no space whatever was wasted. The foundations were one solid mass of concrete, and there was consequently no vibration transmitted outside the building.

Mr. Jeremiah Head said he should like to know, in view of the great extensions contemplated, whether it would not be better to alter the engines to triple-expansion, with a much higher pressure to the boilers; this had been done in other parts of the country. He noticed that the engines they were ordering were simply duplicates of the present ones.

Mr. Gresham Francis, in reply to a question, said that ball bearings had been fitted to the motor generators with a view to economising power by reducing the friction, and to overcome as far as possible any liability to stoppage through inattention on the part of the attendant. They had a small dynamo fitted with these bearings, running at 1300 revolutions per minute continuously from 9 a.m. to 6 p.m. without oil or any attention whatever, and without any signs of heating. Readings taken from the ammeter every fifteen minutes during the day showed a gain in pressure of about 10 per cent. over similar readings taken the day before, under as nearly as possible the same conditions when the dynamo was fitted with the ordinary bearings. In designing these bearings, both the balls and their races must be made from the highest grade of steel, and as hard as possible, as owing to their small bearing surface they would speedily wear out of truth if soft iron case-hardened was tried, but proved a failure, the surfaces soon giving out, and thus causing far more friction than ordinary bearings. The bearings had to be entirely self-contained and easy to adjust, so that any ordinarily intelligent fitter could fit them in place, and adjust for running without any special training. In these bearings the balls were readily got into position by slipping the first of the rings over the flanged sleeve, which was held with the flanged end uppermost. The first row of balls was then placed on the ring and held in position between the ring and the flange, while the whole was turned the other way up. The second row of balls and the second ring were then added, and so on; finally the loose flange was put on and the whole held together by two nuts.

The complete bearing could then be put on to the bracket or pedestal, which was bored to fit the rings, and could be sprung slightly open to allow them to adjust themselves properly, and the whole adjusted by the nuts until the sleeve turned freely, without the slightest shake. The bearings were then ready to be fitted to the shafts. The sleeves were made to fit the shaft snugly unless lateral motion was required, which was sometimes advisable in dynamos, &c. In this case they were arranged to fit freely, and were kept in position by a small sunk key. The number of cored rings depended upon the number of rows of balls required to carry the load, and they were all ground to an angle of 45 deg. with the axis of rotation of the balls. By this arrangement each series of balls was adjusted from a single pair of nuts; the balls were readily put into position, and the whole could be made for a reasonable sum, considering the high quality of the work required. With regard to the thrust on the bearing, there was rubbing at the point of contact between the flanges and the balls; but in bearings where the thrust was light it was so slight, that if the balls were properly hardened the wear was inappreciable.

Mr. Maw asked whether the jockey pulleys were weighted.

Mr. Wordingham, the engineer of the station, did not think the five-wire system any more difficult to work than the three-wire. The bare copper mains were in every way satisfactory, and in his opinion were a better system than any other put down.

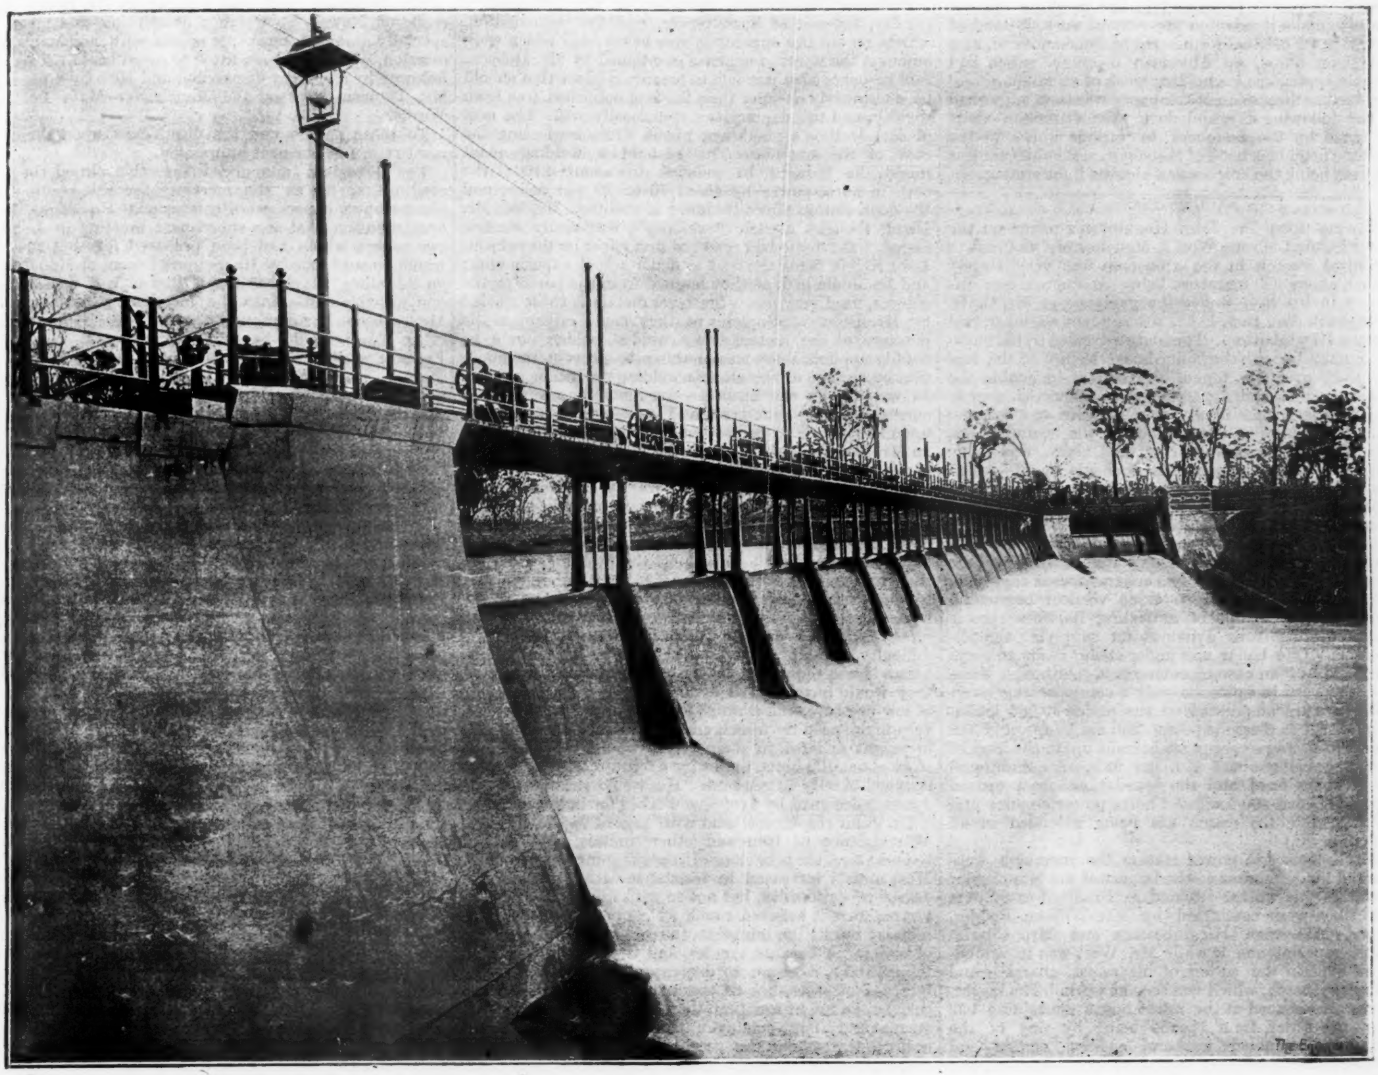
Dr. Edward Hopkinson said, in regard to the ball bearings, he thought they contributed very materially to the good results of the machines.

Mr. C. Richards suggested that to avoid friction in ball bearings, but more particularly in roller bearings, free rollers should be inserted between the balls, and of somewhat less diameter, and this would get over the dragging often experienced.

After several other members had spoken, Dr. John

# THE GOULBURN RIVER WEIR, VICTORIA

(*For description see page* 100)



Hopkinson, in replying on the discussion, said with regard to ball-bearings, of which a great deal had been said, these acted to his entire satisfaction. As to the motor generators, a good deal of the advantage secured was due to the high speed at which they ran—about 1400 revolutions. The motor generators had given them complete satisfaction, and annihilated all cause of trouble from inequality of loads in different sections of the stations. Mr. Head had suggested that triple-expansion engines should be used. Without going into the question of whether it would have been advisable to put triple-expansion engines down in the first instance, he considered that it would now be very doubtful policy to change, when the present engines had run satisfactorily. The jockey pulleys were not weighted or loaded, but set up solidly by means of a screw. There, was, he knew, a strong prejudice amongst mechanical engineers against jockey pulleys, but he might say his experience of them was perfectly satisfactory. With regard to the coal consumed, this would be much less in future than it had been, as the coal strike and other causes had made the cost larger than it would otherwise have been. With regard to the ejector condensers, they knew of course they could not get so good a vacuum as in a jet condenser or surface condensers, but there was greatly increased convenience.

The President called attention to the arrangement of the steam pipes, which was very convenient. He was glad to hear of the good results obtained by using bare copper, as he was personally a very strong believer in that system.

A vote of thanks was then passed to Dr. Hopkinson for his paper.

The Secretary, Mr. Alfred Bache, next read a paper by Mr. B. A. Dobson on "Electric Welding"—an abstract of which will be found on page 99.

In the course of discussion Mr. Saxon said the system of electric welding described by the author was, after all, somewhat limited in its application to smithy work in general engineers' workshops. For instance, they were told that the machine was not capable of piecing bars of iron and steel of more than 2in. diameter, and they were called upon, in breakdown and other work, to piece bars of steel from 2in. to 4in. diameter in an engineer's smithy. It seemed to him that it would be less expensive to couple shafts than to apply such a system as had been introduced to them by the author, particularly in designing new work, they might introduce couplings where they could not get bars of iron of a suitable length; but owing to steel makers and iron manufacturers producing bars of greater length than they formerly did, there was not now so much difficulty in that direction. It appeared to him that the mechanical power required for piecing the bars of iron or steel would be excessive. If 80 indicated horse-power were required to weld a 2in. bar, the power for a 5in. or 6in. bar would be enormous. The expenditure for such a plant as that described would be very great for the requirements of a forge or ordinary engineer's smithy. It was a luxury, not a necessity for such a purpose.

Mr. Cockrill said, with regard to the welding described in the paper, he could only say they could do anything if they had power sufficient. Mr. Saxon had spoken of the large cost which would be incurred in piecing a 5in. or 6in. shaft, but he—Mr. Cockrill—thought the cost was very moderate, as it would only take 130 or 140-horse power for a 6in. shaft, and it would only require a few minutes to piece. It could, therefore, hardly be called a luxury.

Mr. Jenkin said it was a very undesirable thing to put down an electric welder to run from a main shaft. Mr. Dobson had, however, succeeded. Concerning the tests for the power, the great difficulty with an electric welder was estimating the time. He would suggest to Mr. Dobson that a continuous recorder should be put on the steam engine, such a one as Mr. Storey, of Manchester, had, which, if put on a machine for electric welding, would give a very accurate estimate of the horse-power for each weld. The proportion of failures was certainly remarkably small—not one out of 500. At Crewe the percentage was much larger.

Mr. Worthington said he thought the method adopted by the firm of finishing the welds, swaging was to a large extent the cause of its success. In irregularly shaped bars which were sometimes welded by electricity it was impossible to swage after the welding had been performed. Mr. Dobson had pointed out that the largest sizes he had welded were 2¼in. in diameter. It had been his good fortune to witness the welding of much larger sizes, although he was sorry to say he could not give the exact power absorbed. Three square inches were frequently welded in making the crossings of electric street rails. The machines used were really treble machines, one being a large welder carried on a crane and simply deposited on the top of a section; then a horizontal machine on either side was brought forward, also in contact with the surface, each welding machine being under the control of a man. The arrangement was such that immediately one weld was finished another section was ready to bring round to the machine, and in this economy of time would lie the success of electric welding machines. With regard to the arc welding, this was very successful for ordinary commercial and other purposes. It consisted of a carbon arc light, one part of which was held in the hand, and screened from the face of the operator by a large semi-opaque disc. The operator had four powers under his control, *i.e.* he could bring one, two, three, or four measures of current to bear upon the work. This process was used chiefly for local welding.

Mr. Webb bore testimony as to the quality of the work done at Messrs. Dobson and Barlows'. The system would not, however, do for a jobbing shop.

Mr. Jeremiah Head thought the term electric "welding" was inapplicable to the process it sought to name; would not electric "fusion" be a better term? What had generally been understood by "welding" was the property of metals, such as iron, of becoming plastic at a temperature somewhat short of fusion, and if the surfaces were perfectly clean, and brought together by some form of pressure, they would apparently become homogeneous. They could scarcely conceive of wrought iron and cast iron being brought together and united in the same way as by what had generally been called "welding." It was more, it seemed to him, a fusion of the surfaces. Some kinds of iron were exceedingly difficult to weld, and the curious thing was that it was the purer or "drier" irons that were the most difficult to weld, because they did not contain any of that silicate of iron or flux which enabled the surfaces to be kept perfectly clean when brought together. How Mr. Dobson managed without the flux he (Mr. Head) could not quite understand.

Mr. Charles Cockson said with a 1in. bar only 23-horse power would be required, and therefore for a section of 2in. 92-horse power would be necessary.

Mr. R. H. Tweddale, London, said there appeared to be great difference of opinion as to the power to be applied in welding to bring the ends together. He had seen in a paper read in America a statement that a 2in. bar required 75-horse power through 95 seconds, whilst Mr. Dobson gave 88-horse power through 250 seconds, and Sir Frederick Bramwell gave 50-horse power through 55 seconds.

Mr. Aspinall said the identical machines described by Mr. Dobson had for three or four months been tried at his own works, and his experience agreed with that of Mr. Dobson, in thinking that when starting they would require only 30-horse power, whereas they needed 80; but, in his case, after going into the matter carefully, and doing a considerable amount of work both with solid bars and tubes, they had to give it up, as they found it impossible to do any "commercial" work with it. It was more expensive than doing the work by hand. One peculiarity about the machine was that it was only adapted for holding straight work; for irregularly-shaped pieces the machine was practically useless, and he was surprised the people interested in the machine did not attempt to make it adapted for general work, instead of leaving it in its original form. He had once noticed, at a Birmingham Show, an American machine, which had admirable appliances for holding work of all kinds.

The further discussion of the paper was then adjourned until the following day, and during the afternoon visits were made by the members to various works in the immediate neighbourhood of Manchester, the chief centres of interest being the corporation electric light station.

### EXCURSIONS.

Following upon Dr. John Hopkinson's paper on the "New Electric Lighting Works, Manchester," the visit to the central station in the afternoon was very largely attended, about 220 members being conducted over the premises in batches, under the guidance of Mr. C. H. Wordingham, Ass. Inst. E.E., the resident engineer, and Alderman Higginbottom. The route traversed by the members commenced with the boiler-house, thence to the coal store, then over the top of the boilers to enable the duplicate system of steam-piping to be inspected, next to the economisers, and, finally, to the engine and dynamo room. Much interest was evinced in the coaling stage, where the fuel, consisting of washed slack, was being raised from barges lying in the Rochdale Canal—which skirts one side of the building—by means of an electric traveller, the gantry for which runs along the range of hoppers for feeding the Vicars' mechanical stokers. This traveller works quietly and smoothly, and the speed, both of traversing and lifting, can be regulated at will by means of a resistance. There were two boilers at work supplying steam at 125 lb. pressure to three vertical compound tandem engines capable of indicating 100-horse power each, and driving three dynamos for supplying the all-day circuit. One boiler was under steam ready to serve as a "stand by" in case of emergency. Although these works have been in existence only a comparatively short period, there are at present on the mains 39,268 incandescent lamps of 8-candle power, 256 arc lamps, and ten motors, the average charge for current up to the end of March last being about 5½d. per unit. An additional boiler is being fixed, and the foundations are prepared for two additional 400-indicated horse power engines and dynamos, while the mains are being extended in all directions.

From the electric power station the members were conducted by omnibuses to the largest of the Manchester Corporation gas works, situated in Bradford-road, over which they were conducted by Mr. William Rodger, manager, Alderman Higginbottom and Mr. Charles Nickson, superintendent, while Mr. West was in attendance to explain the action of his retort charging and drawing apparatus, which was seen at work. The inspection was commenced at the retort house containing 952 retorts, the order from thence being by way of the washers and scrubber washers, coolers, engine and exhauster house, purifying shed, new gasholder tank, and finally to the station meter and governor house. The area covered by these works is nearly fifty-two acres. There are two retort houses capable of carbonising 850 tons of coal and cannel daily, producing 8,500,000 cubic feet of gas. The retort settings are constructed on the regenerator principle. No. 1 house, with 488 mouthpieces, is worked with West's charging and drawing machinery, comprising air compressor, air receivers, air pipes and drums, coal breakers, elevators, and coal hoppers. No. 2 house, with 474 mouthpieces, is at present worked by hand, but arrangements are being carried out for the use of stoking machinery. There are four gasholders with three lifts, constructed on the telescopic principle, with a total capacity of 6,800,000 cubic feet. A new gasholder tank is being constructed by Mr. James Nuttall, of Manchester, for a holder capable of containing 7,000,000 cubic feet of gas. The holder itself is being built by Messrs. Ashmore, Benson, Pease and Co., of Stockton-on-Tees; the outer lift will be 250ft. diameter by 50ft. deep, the middle lift 247ft. diameter by 50ft., the inner lift 244ft. diameter by 50ft. The total cost will be about £250,000. The number of men employed varies from 675 to 353. These works have good sidings for railway wagons, and are in direct communication with the Lancashire and Yorkshire Railway; and the Ashton and Oldham Canal runs by them.

The capacity of these works will be gathered from the following table:—

| RETORT HOUSES. | | | | | | STORAGE. | | | | | | | | | Station meters | | Purifiers. | |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| No. | No. of beds of retorts. | No. of mouthpieces. | System of charging. | Carbonising power. | Producing power. | Gasholders. | | | | | | Cannel. | Coke. | Tar and ammoniacal water. | No. | Hourly capacity. | No. | Hourly capacity. |
| | | | | | | No. | Dia. of outer lift. | No. of lifts. | D'pth of each lift. | | Capacity. | | | | | | | |
| | | | | Tons. | Cubic feet. | | ft. | | ft. | in. | Cubic feet. | Tons | Tons. | Gallons. | | Cub. feet. | | Cub. feet. |
| 1 | 28 | 334<br>154 | M'chine<br>Hand | 410 | 4,100,000 | 1 | 150 | 3 | 33 | 4 | 1,700,000 | 30,000 | 30,000<br>(say) | 1,940,000 | 1 | 150,000 | 8 | 150,000 |
| 2 | 28 | 464 | Hand | 400 | 4,000,000 | 2 | 150 | 3 | 33 | 4 | 1,700,000 | | | | 2 | 150,000 | 8 | 150,000 |

The price of gas in the city of Manchester is 2s. 6d. per 1000ft., and the standard illuminating power equal to twenty candles, to obtain which the fuel employed consists of cannel and ordinary coals in the proportion of about two to one. Alternative visits were arranged to Messrs. Thomas Hoyle and Sons' calico printing works, Buxton-street, London-road; Messrs. S. and J. Watts and Co.'s warehouse, and to the printing works of the *Manchester Guardian* and *Evening News*. In the evening the members attended a conversazione in the Town Hall, on the invitation of the Lord Mayor.

The discussion was resumed on Wednesday, when there was again a full attendance of members. The President, Professor Kennedy, occupied the chair.

Professor Watkinson, referring to the payment of royalty, the cost of horse-power, and the depreciation, which, on electric apparatus, was heavy, and which were amongst the items of expense mentioned by Mr. Dobson, said he believed it possible to arrange a plant that should be enormously cheaper than the one described, free from royalty, and the depreciation practically *nil*. The cost of Mr. Dobson's plant was about £700, neglecting the cost of the engine. The cost of a welding plant might, he thought, be reduced to about £100; the cost in horse-power by about 70 to 80 per cent., and the depreciation almost reduced to nothing. He, like Mr. Head, thought electric "welding" was really electric fusion. Dr. Joule had read the first paper on the subject, Lord Kelvin being the first to make actual experiments; and Dr. Joule had, as they learned from the paper on the subject, used very much the same metals as those welded by Mr. Dobson. So long as they could rely upon the pressure of the metals being welded, which could be readily applied, there was nothing to prevent the adoption by anyone of the electric welding or fusion process. In welding by the incandescent method, a very large current was required at a low pressure, depending upon the metals to be welded and their sectional area. In Mr. Dobson's plant, the large current was generated in an alternator at a high pressure, and then transformed to the necessary pressure by a transformer, and the plant was altogether a very complicated one, and liable to get out of order, to say nothing of the cost. If, instead, they had a dynamo to give them a large current direct, and put the welding table on the dynamo, they would then get over all the difficulties, so long as they only required one or two welding tables, which would be quite sufficient for ordinary works. In ninety-nine cases out of a hundred they would avoid the difficulty of taking the 20, 30, or 40 thousand ampères to where it was required. In the arrangement he suggested they would have a small dynamo to give a large current at low-pressure, and arrange it to be belt driven, using a very high-speed fly-wheel, and then with a wheel 5¼ tons in weight and 6ft. in diameter, it would be possible to store about 100-horse power for a minute, with a decrease in speed of only 10 per cent. He would recommend the dynamo designed by Professor Forbes for large currents.

Dr. John Hopkinson said with regard to the increase of resistance of iron and other metals with rise of temperature, the behaviour of iron was somewhat peculiar. Most metals increased in resistance with a considerable degree of uniformity, but not so with iron. To a certain temperature it behaved much as copper and other pure metals; but as the temperature rose the rate of increase of resistance became greater, and then, at a very high temperature, it began to decrease. With regard to the increase of resistance of conductors with an alternating current, he might mention that, with a large alternating current and a large conductor, they did not get the current uniform throughout the section of the conductor. The current was to a large extent confined to the outer portions of the conductor, owing to magnetic effects, into which he would not enter. The method of electric welding had been called a "luxury," but they must remember that the luxuries of to-day are the necessities of to-morrow.

Mr. Parker said electricians could very much help mechanical engineers in developing electric welding; but at present the method was very cumbersome. He was sorry to hear of the failures at Crewe, and the unsatisfactory results from a commercial standpoint experienced by Mr. Aspinall. He remembered that Sir Wm. Siemens had in 1881 done work similar to that mentioned by the author in welding and fusing steel, platinum, &c., almost in the manner described in the paper.

Mr. Dobson, in replying upon the discussion, said with regard to Mr. Saxon's remarks, that gentleman had somewhat misunderstood him. When he had spoken of bars only up to 2¼in. being welded, he had only referred to the power of one particular machine. They could as easily make a weld on a 12in. shaft as a 2in. shaft. With regard to the unsatisfactory experience at Crewe, he thought the necessity of swaging had been overlooked. In a metal like iron there must be a certain amount of swaging, or the weld would be imperfect. Other metals did not require it, but in the case of iron and some of the lower qualities of steel it was an absolute necessity. Mr. Aspinall, who had had the machines under his control before they came to his own firm, had been less fortunate in his experience than he had. Mr. Hopkinson had asked whether in hard steels the temper was affected by welding. In such cases, after the welding was done, the temper was of course destroyed, but the operation of welding did not appear to put the slightest difficulty in the way of re-tempering, this was done quite as easily all through a built-up bar as it was originally. He did not find that there was any minimum point where the resistance was least, except that, as the current was gradually increased, the resistance at first was least. The President said he had in the winter 1888-90 spent some weeks in the States examining the process Mr. Dobson had carried out successfully in England.

A vote of thanks was then passed to Mr. Dobson for his paper.

The Secretary next read a paper by Mr. Henry Barcroft, of Newry, in which a description was given of specially-designed screw propellers with adjustable immersion, which had been fitted to canal boats. This was followed by a lengthy discussion, and then by a paper by Mr. Thomas Olive on the Manchester Main Drainage Works.

To these papers, and the discussions upon them, we must return in our next impression.

The President announced that this closed the proceedings, so far as the meetings for the reading and discussion of papers were concerned. He might, however, mention that at a subsequent meeting in London, two papers which had been prepared for that meeting would be read, one by Mr. Samuel Dixon, of Manchester, on "Drilling Machines for Cylindrical Boiler Shells," one of which machines the members saw who visited Mr. Joseph Adamson's works at Hyde. The other paper would be by Mr. Charles J. Hewitt, of Prescot, on the "Manufacture of Standard Screws for Machine-made Watches," the interest of which would no doubt be considerably increased by the visit some of the members were paying to the Lancashire Watch Factory at Prescot on Friday. Mr. C. Woodall had also promised a paper on "The Hydraulic Supply Station of the Manchester Corporation;" but this he had not been able to get quite ready, and it would be read at a subsequent meeting.

In conclusion, the President proposed the following votes of thanks, which were heartily endorsed by the members:—To the Council of the Owen's College for their kindness in inviting the Institution to meet there, and the facilities they had offered to the meeting throughout; to the Executive Committee, particularly the Lord Mayor as chairman, the Mayor of Salford as vice-chairman, and Mr. Charles Hopkinson as hon. secretary, for the admirable arrangements they had made for the visit, which would always be a pleasant recollection; to the Lord Mayor—Sir A. Marshall—for his handsome reception at the conversazione in the Town Hall; to the proprietors of the various engineering and other establishments which were open for inspection, and to the several hosts who had so hospitably arranged for the entertainment of the members on the occasion of their visit; to the directors of the London and North-Western and Lancashire and Yorkshire Railway Companies for their kindness in offering special facilities for the excursions over their lines.

The proceedings then terminated.

The Institution Dinner was held at the Grand Hotel, Manchester, on Wednesday evening, and about 300 members sat down. The chair was occupied by the President—Professor Kennedy—and amongst those present were Sir Anthony Marshall, the Lord Mayor of Manchester; Sir William H. Bailey, Mayor of Salford; Wm. Mather, M.P., Alderman Sir Bosdin T. Leech, Mr. John Ramsbottom, first President of the Association; Alderman John Hopkinson, President of the Owen's College; Sir E. Leader Williams, Engineer-in-chief to the Manchester Ship Canal; and Mr. J. K. Bythell, Chairman of the Manchester Ship Canal Company.

The visits arranged for Wednesday comprised the Manchester Ship Canal, the Corporation Hydraulic Power Supply Station, the Manchester Packing Warehouse, and the chief Fire Brigade station in Jackson's-row. Of these, that which received by far the largest patronage was the Canal, the members being conducted from Owen's College to the Pomona Docks on omnibuses, and here they embarked upon the Manchester Ship Canal's Passenger Steamship Company's steamer Eagle, on board of which were also Sir Edward Leader Williams, engineer of the undertaking, and Mr. S. Platt. From the Pomona Docks the vessel steamed up the canal as far as Irlam Locks, passing on her way through the Mode Wheel and Barton Locks. The members were thus enabled to witness the turning of the Trafford-road swing bridge, the Barton aqueduct, which serves to carry the Bridgewater Canal over the principal waterway, and the Barton-road bridge. The otherwise pleasant and interesting trip was somewhat marred by the unpleasant odour which arose from the water, and which seems to have become much more perceptible than when we visited the canal some few months ago. Although this obnoxious smell is no doubt due in a large measure to the pollution of the upper parts of the river Irwell by the numerous and varied factories, chemical and otherwise, which are situated on its banks, yet the delay in the completion of the sewage works of Manchester and Salford is certainly responsible for a large portion of the pollution, since the canal itself acts in large measure as a huge settling tank, in which decomposition takes place. With the completion of the abovementioned sewage schemes, and when the Rivers Pollution Act can be more rigidly enforced, a corresponding improvement will take place in the condition of the water. At Twenty Steps Bridge, near Latchford, a turbine and pump, which we may illustrate in a future number, are being fixed by Mr. C. L. Hett for use in making a subway under the culvert. On the day of the visit there appeared a fair amount of shipping, and some nine or ten steamships were berthed in the docks at the Manchester end. The Pontoons and Dry Docks Company, Limited, whose premises are situate on the bank of the canal at Mode Wheel, received very extensive damage on Tuesday night, owing to a fire, by which a wooden structure serving as an oil and paint shed was entirely destroyed.

Of the other works of interest inspected on Wednesday, the pumping station of the Manchester Corporation Hydraulic Power Supply commands chief notice. The buildings forming this station are in two blocks, divided by a roadway giving access to the yard and to the Rochdale Canal. The main building consists of an engine house, boiler house, accumulator tower, and coal store. The office block has a show room for hydraulic appliances on the ground floor, with offices above approached by a staircase with a hydraulic balance-lift working in the well-hole; behind the office is a residence for the foreman, with workshop and stores. The engines are at present four in number; but two additional engine foundations are prepared, and it is possible that within a year the station will be completely furnished with pumping plant. The type adopted is the inverted triple - expansion surface - condensing pumping-engine, each engine upon trial indicating rather over 200-horse power; the specified duty is the delivery of 230 gallons of water per minute against an accumulator pressure of 1120 lb. per square inch, with 120 lb. per square inch steam pressure, the piston speed not exceeding 240ft. per minute. The steam at 120 lb. pressure is supplied by five steel Lancashire boilers, each 30ft. long by 7ft. 6in. diameter; they are furnished with Vicars' mechanical stokers, and have two Green's economisers of 360 pipes together. The coal is brought from the coal store to the stoker hoppers by means of a ladder elevator discharging into a worm conveyor trough, which is carried along the wall of the boiler-house; this in turn feeds the conveyor extending over the boiler fronts. Coal is delivered to the station either by barge or by road, and is handled by a 30 cwt. hydraulic travelling crane. Three-cylinder Brotherhood hydraulic engines are provided for actuating the conveyors, stokers, and economiser-scrapers in the boiler-house, and also for working the lathe and drill in the fitters' shop. The two accumulators have rams 18in. diameter and 23ft. stroke, and are loaded to give a minimum pressure of 1000 lb. per square inch at the consumers' machinery. The station having been opened in the present year is not yet working to its full capacity. The number of machines already connected, and others for which contracts are pending, is so large, however, that in a few months the four engines already installed will be barely sufficient for the work to be done. The works are in charge of Mr. F. M. Evanson, resident engineer, but were designed by Mr. Corbet Woodall, who has promised to read a paper upon them before this Institution.

## THE IRON TRADES EMPLOYERS' ASSOCIATION.

THE annual general meeting of the members of the above Association was held at the Grand Hotel, Manchester, on Monday, and, being practically at the same time as the summer meeting of the Institution of Mechanical Engineers, also being held in Manchester during the week, there was a good attendance of representatives from the various industrial centres over which the organisation of the Employers' Society extends. The chair was occupied by Mr. B. A. Dobson, the president. The twenty-second annual report of the General Committee of Management, which was presented to the meeting, dealt briefly with various matters of importrnce which had come before the Association during the past year. Commenting, in the first place, on the state of trade, the Committee expressed their regret that they could report no general improvement in the shipbuilding and engineering industries. At the beginning of the current year, a slight spurt took place on the North-East Coast, but since then trade had been on the decline, and was now bad. In nearly all the other districts where the Association had organisations, trade was reported as dull or bad, with little signs of improvement. Some firms had secured a fair amount of work, and were still tolerably busy, but this was confined more particularly to makers of specialities, or machinery where foreign competition was not so much in evidence as in the general engineering trade. The reports of the various trade societies also showed a considerable decrease in their funds, and a considerable increase in the number of unemployed members on their books.

With regard to labour and wages questions, the principal disputes that had occurred to disturb the relations between employers and employed during the year had been on account of wages. On the North-East Coast the Amalgamated Society of Engineers and the Machine Workers applied for advances; the notices were afterwards withdrawn. The moulders and patternmakers, however, went out on strike for an advance of 3s. 6d. time wages, and 10 per cent. piece rates, on the 20th March and 7th April respectively. These demands were afterwards reduced to 2s. and 5 per cent., but no advance of any kind had been granted by the employers, and the men were still out on strike, with little prospect of a settlement, the employers feeling that if they conceded the moulders' and patternmakers' demands, they could not consistently refuse an all-round advance of wages to other workmen, which would result in disaster to the whole trade. After detailing the steps which had been taken to assist their members on the North-East Coast in resisting the demands of the workmen and obtaining a supply of castings from other quarters, the report refers to the action taken in several districts by the leading trades societies who had set their face against overtime, and had made attempts to limit it, at any rate as much as possible, "but, unfortunately," the report somewhat sarcastically adds, "there has been little necessity to work any overtime whatever on account of the state of trade."

Next turning to the eight hours' question, the report goes on to state that there had, during the past year, been a move towards a reduction of working hours to forty-eight per week by several firms unconnected with the Association; and one in particular, Messrs. Mather and Platt, of Salford, had adopted the system. The Government had now followed suit, not only in the various arsenals and workshops connected with the War Department, but since then in the various Admiralty dockyards. The Employers' Association Committee feeling keenly that the hands of employers of labour all over the country might be forced by the recent developments, had done what they could to place the effects of a general movement in this direction before the trade and the public, and with, it was hoped, some beneficial effect. Messrs. Mather and Platt had issued at the end of their trial year a lengthy report, showing the working of the system, and stating that the firm had sustained no loss by the reduction of hours. The committee of the Iron Trades Employers' Association had, however, replied to that on several occasions, and had adduced many forcible arguments which had not yet been traversed by the persons who defended the system of forty-eight hours, and more especially in a pamphlet which was issued to the members and other employers of labour all over the country, as they felt that whatever the effect on an individual firm during a short period in a limited area, once the movement became general it would result in a very large increase in the cost of production, and therefore mean ruin to many firms.

The agreement reached last December between the Iron Trades Employers' Association and the Boilermakers and Iron Shipbuilders' Society for the better regulation of apprentices was also referred to, and the Committee expressed their trust that this agreement would have a good effect upon the relations between employers and their workmen in the above industries in the future. In conclusion, the Committee expressed their regret that Exemption of Machinery from Rating Bill had not yet been passed into law; the amended Employers' Liability Bill had, however, been thrown out by the House of Lords, and the old Act was still in operation.

The President, in moving the adoption of the report, referred to the increasingly antagonistic attitude that was being taken up by trades unionism towards employer generally, and in the engineering trades especially, which had become a serious element in the outlook for the future.

The report having been unanimously adopted, a discussion took place with reference to the moulders' strike on the North-East Coast dealt with in the report, and it was decided that the situation, so far as the employers were concerned, should remain unchanged until September, when the matter would again come under the consideration of the executive.

The usual committees having been appointed, and votes of thanks passed to the retiring officials, Mr. B. A. Dobson—Messrs. Dobson and Barlow, Bolton—was unanimously re-elected president for the ensuing year. The proceedings were then brought to a close with the annual dinner, the President occupying the chair.

## ELECTRIC WELDING.*

*Experience in electric welding.*—Practical every-day working for nearly three years of the process of welding by electric force enables the author to give certain indications of the method considered as a practical workshop operation. During this period his firm has had two machines in operation, worked from the same generating dynamo, and employed on different classes of work: one is specially arranged for piecing bar iron and steel; and the other and smaller machine for special classes of work of a more delicate description, such as brazing and the piecing of clean-finished work, where the fire heat would have destroyed the quality of the work on the adjacent material.

*Mechanical power.*—The statement made with regard to the requisite mechanical power placed great difficulties in the way at first, as it was found that this power had been much understated. Having something like 35 indicated horse-power to spare on a certain engine, and understanding that 30-horse power would be the utmost wanted in order to piece a 2in. round bar, the author determined to drive the dynamo from this engine, particularly as it was in close proximity to the smithy and stretching shed, where this piecing was previously effected by means of the ordinary smith's hearth. By this practical test it was found that not 30-horse power, but as much as 80-horse power seemed to be required for the larger sizes; and until this was understood, the engine was frequently stopped for want of steam, occasioning great loss and inconvenience. The company having control of the welding machine suggested that they should supply a semi-portable engine and boiler; and that this should be tried, with the option of purchase after a certain length of time, if approved. This was agreed to, and a portable engine by Messrs. Marshall, of Gainsborough, capable of working up to 100 indicated horse-power with 80 lb. pressure, was supplied and placed at a distance of about 45 yards from the welding machine. This got over the difficulty of power, but was of course more expensive on the score of separate attendance and other cost. But even with this engine it was found that, when piecing the larger diameters—and as yet nothing over 2¼in. has been pieced—if the work was to be done within a reasonable time, the engine was seriously checked in speed. It was therefore with a view to be certain as to the basis of calculation for the necessary expenditure on driving power that the experiments which follow were conducted.

After some months' working with the portable engine, it was proved satisfactorily that the process was a practical one, and, so far as the results to the author's firm were concerned, a success. As considerable enlargements were about to be made to the establishment, a portion of a large dynamo-room for electric lighting purposes was set apart for the welding dynamo and exciter; the distance of the leads from the dynamo to the welding machine was approximately 100 yards. Having a quick-running vertical engine of the kind made by Messrs. Fleming and Ferguson, making 140 revolutions per minute, with an extra heavy fly-wheel and abundance of surplus power, the author has been able to work the larger diameters without affecting the steadiness of the arc lamps driven off the same engine; and as the load will vary 80-horse power in the tenth of a second, this result speaks well for the arrangement of the engine and for its governing powers. The greatest variation in voltage of the lighting dynamos has been two volts.

*Dynamo.*—The Thomson-Houston welding dynamo is an alternating current machine. Its speed is 1000 revolutions per minute, and it gives at full load a current of 200 ampères at 300 volts, having a frequency of 100 complete alternations per second. The machine is excited from a continuous-current dynamo giving 40 ampères at a pressure of 110 volts. The large welder is capable of piecing iron or steel bars up to 2in. diameter.

*Transformer.*—The primary coil consists of forty-one turns of 0·452in. copper wire. These are coiled round an iron core formed of thin sheet iron plates bolted together. The secondary circuit consists of a single massive copper tube 1¾in. diameter inside and 3¾in. outside, passing through the centre of the core, and connected at the two ends with massive castings 6¼in. broad by 3in. thick, which support the welding clamps; one clamp is kept stationary during the welding, and the other is movable. The pressure is obtained by a screw and hand-wheel, forcing the movable clamp towards the fixed clamp.

*Good and bad welds.*—It must not be imagined that a good weld can always be made by pressure alone. No doubt if the material were perfect in character and thoroughly homogeneous, this might be the case. The iron and steel of commerce are not perfectly pure; and in order to make certain that the work may be subsequently depended upon, it is advisable that the burr formed by the pressure should be reduced by hammering in swages.

The ordinary surfaces of bars, whether cut by shears or broken with the chisel and hammer, are found sufficiently uniform to permit of welding, without further preparation. Should there be dirt or rust upon the surfaces, it is easily expelled when the metal is sufficiently soft to allow of the end pressure of the screw necessary to form union, and the dirt, scale, or oxide makes its way to the exterior.

*Work done.*—In common practice at the author's works the following materials have been heated, and the undermentioned work has been performed. Welding of steel of every quality, iron of every description, from crown to best roller iron and charcoal iron, steel and iron together, wrought iron, and cast iron; different diameters of the same and different materials. Riveting in many varieties; work which previously had to be riveted cold, and which consequently left the strength of the parts uncertain, is now done easily and certainly with the requisite heat. The piecing of counter-shafts and lathe spindles, where the question of exactness of length is of the utmost importance; screwing taps, rollers, and spindles broken in the neck bearings, and brazing of all descriptions have all been successfully treated.

*Power required for electric welding.*—These tests have been confined to the welds required in everyday work, and have varied from ¼in. steel and iron to 2in. as shown in Table 1. The measurement of the alternating-current power supplied to the welding transformers is attended with some little difficulty, owing to the short space of time during which the current and electromotive force are practically steady. As also every piece of iron varies in resistance, though cut from the same bar, the power registered is continually varying in the welding of bars of the same diameter. Another cause, accounting to some extent for the different powers obtained with the same size of shafting, is that the rheostat is not always worked from the same segment of the coils through the adding or deducting of the resistance, and consequently causes a greater or less excitation of the field of the alternator, thereby producing a greater or less electromotive force. A Siemens electro-dynamometer was connected in series with the thick-wire coil of a Siemens watt-meter, the latter being in series with the primary coil of the electric welder. Connected across the terminals of the welder was the thin-wire coil of the watt-meter, in series with a non-inductive high resistance. A Siemens voltmeter for the measurement of alternating volts was also connected across the terminals of the welder. By this means the virtual volts and the virtual ampères were estimated with sufficient accuracy; and at the same moment a reading was taken from the watt-meter, giving the true watts absorbed in the transformer. At the time of taking the instrument readings, indicator diagrams were taken from the engine, which afford a considerable check on the results obtained from the watt-meter. In order to estimate accurately the power taken for each weld, it is necessary to add the power required to excite the alternator, and the power lost in transmission. For this purpose the resistance was measured of the mains supplying the current to the primary coil of the welder, and also the resistance of the mains carrying the exciting current; the former was 0·2 ohm, and the latter 2·6 ohms. The electrical horse-power given in the table is obtained from the true watts shown by the watt-meter, divided by 746, and the loss in the mains and in the exciting current is got by calculation; the loss in friction is the amount of power required to work engine, alternator, and exciter, at no load.

*Conclusion.*—The practical experiments made in the author's works show that in bending cold the weld has rarely given way. But in explanation of this it must be borne in mind that all the piecings of plain bars are more or less swaged. It is well within the mark to state that there is not one out of five hundred welds which turns out a failure or even defective.

The question of cost, which is of course of importance to commercial engineers, has not been alluded to in detail. The author admits, however, that the payment of royalty, the cost of horse-power, and the depreciation which on electrical apparatus is heavy, together bring the cost considerably over the net cost of the ordinary smith's hearth work, while the actual payments in wages and so on are considerably less. The loss in weight of iron is about one-twentieth only. It may be taken that on straightforward welds the total cost will be between 10 and 15 per cent. more than the ordinary smith's work; whereas in delicate work and difficult operations, such as have been alluded to, the cost will probably be one-third of the smith's work. But the real advantage of the apparatus, at any rate as at present arranged, is not so much an economy as a method of securing an absolutely reliable result, and occasionally saving considerable expenditure by its special adaptability.

TABLE I.—*Power Expended in Electric Welding.*

| Work welded. | 1894. | Duration of current. | Electrical horse-power. | | | | Indicated horse-power. |
|---|---|---|---|---|---|---|---|
| | | | $\frac{\text{Watts}}{746}$ | Loss in mains and in exciting. | Loss in friction. | Total. | |
| | May. | Seconds. | E H.P. | E.H.P. | E.H.P. | E.H.P. | I H.P. |

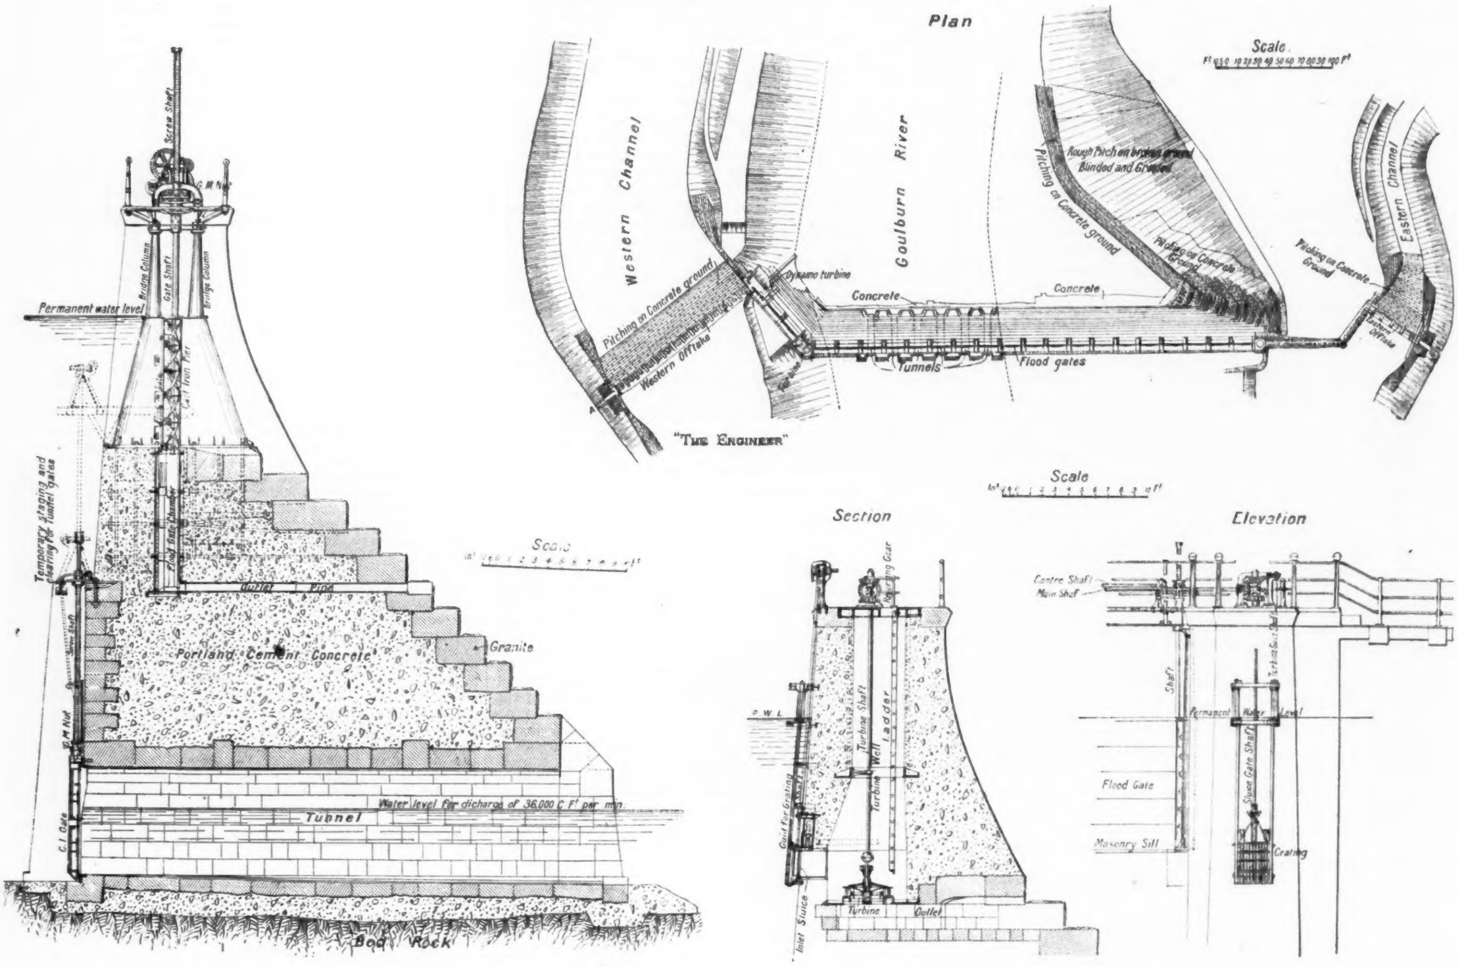
# THE GOULBURN RIVER WEIR, VICTORIA

MR. STUART MURRAY, MELBOURNE, ENGINEER



## THE GOULBURN RIVER WEIR, VICTORIA.

A DESCRIPTION of this weir and its dependent system of works, with numerous illustrations, has been prepared by Mr. Stuart Murray, Chief Engineer of Water Supply, and published at the cost of the Victorian Government. Mr. Murray states in the introduction that this description has been prepared with the expectation that it will prove serviceable as well as interesting to engineers, and in order that the details of a work so important and costly may be subjected to the fullest and widest criticism.

The most serious difficulty with which Australia has to contend is the severe droughts which periodically occur, and there is no question that has attracted so much general attention throughout these colonies as that of irrigation and the storage of water. A Royal Commission, which was appointed in 1884 to investigate this subject for New South Wales, reported that on water conservation mainly depended the prosperity and development of the whole extent of the central and western divisions of that colony; that the purposes for which water conservation and storage are chiefly required are to provide fodder and grain for horses, cattle, and stud sheep; to afford a supply of water to be kept in reserve for saving stock of all kinds in bad seasons; to produce fruit, vegetables, and miscellaneous crops, and to increase generally the productive powers of the land. Following on this Commission a report was prepared by Mr. H. G. McKinney, the Government engineer, detailing the results of investigations made, and advising a scheme for storing and distributing the water of the Upper Murray river at a cost, including the distributing works, of £1,412,250. The reservoir was estimated to be capable of supplying 1800 cubic feet per second, which it was considered would be sufficient to irrigate 270,000 acres, yielding a gross revenue of £177,500 a year, and after allowing for interest on outlay, management, and maintenance, leaving a clear profit of £100,000 a year. So far, the irrigation works in New South Wales have not been carried out to any great extent, and such as exist are due principally to private owners, the supply being afforded generally by pumping. The most successful of these works are those carried out by Messrs. Chaffey at Mildura, where the water is taken from a watercourse in connection with the river Murray and raised by steam power to heights varying from 50ft. to 80ft. There are several pumping stations, the largest working four centrifugal pumps, requiring engines of 1000-horse power. The water is distributed through iron pipes, and sufficient is provided to irrigate about 30,000 acres. The crops grown on the cleared and irrigated land are maize and wheat, and a large area is planted with vines and fruit trees. Mildura has become a fair sized town, and the settlers are reported as being well satisfied with their prospects.

In Victoria works have been carried out by the Government, hereafter described, capable, when completed, of irrigating 775,000 acres of land. There are two Water Trusts which take their supply from the National Channel, and which have about 400 miles of irrigating channels. Within the area of the Rodney Trust 1000 acres have been prepared and planted with fruit trees, and 2000 acres been laid down with lucerne, maize, and various other kinds of fodder crops. The fruits include raisins, vines, wine grapes, apricots, and apples; and the price charged for water by the trust is Rs. ½ for 1000 gallons.

As the result of experience in the use of irrigated land for fruit growing in this district, there is a considerable diversity of opinion. Several of the largest fruit growers who were at one time favourable to the formation of irrigation trusts are now opposed to such a course, contending that crops of fruit can be grown as large and as of good a quality without artificial watering as with it, or, at all events, that the advantages of watering do not pay for the cost it entails, so they are entirely of the opposite opinion. Where, however, the holdings are small, the benefit from irrigation is generally admitted. The works which have been carried out by Mr. Murray for the Victorian Government are of a very extensive character.

The Goulburn river, a tributary of the Murray, is the largest and most permanent of the Victorian rivers. The area of its watershed above the newly constructed weir is 3940 square miles; the area below the weir is 2500 square miles, which consists principally of alluvial plains. The irrigation of this plain has supplied the motive for the construction of the weir and its dependent system of works.

The least volume discharged by the river during nine years when gaugings were taken was 2500 cubic feet a minute, and the greatest volume 1,923,000 cubic feet a minute. Floods do not occur suddenly, but give a fair amount of warning. The greatest rise in the level of the river at the site of the weir in twenty-four hours during the four years the works were in progress was 10ft., and the greatest fall in the same time 8ft.

The Commission reported in 1886, and soon after a Bill was obtained in Parliament authorising the construction of the weir, and declaring it to be a national work, under the provisions of the Irrigation Act. A contract was obtained in the following year, and the work commenced immediately thereafter. The weir is 695ft. long, exclusive of the space occupied by the channel regulators, which add a further 230ft. It raises the summer level 45ft., the extreme depth from the still water surface to the river bed being 50ft. The foundation rests on alternating beds of sandstone, slate, and pipeclay, standing on edge almost vertically. The body of the work is cement concrete, backed with steps of carved granite. Across the natural channel of the river six tunnels were formed beneath the site of the weir, each having a sectional area of 44 square feet. These were designed to carry away the water due to the ordinary flow of the river while the superstructure was in progress. These tunnels were provided with iron gates, which were permanently closed on the completion of the work. As these tunnels provided for the escape of the water in summer, the construction of the superstructure gave very little difficulty. On several occasions the river floods rose sufficiently high to overtop the work in progress, but did not do any material damage.

The body of the weir is not monolithic, but consists of large blocks of concrete banded together, bedded and jointed in cement mortar. This course was adopted with the object of preventing the cracks that are inevitably developed in a mass of monolithic concrete. The blocks are composed of one part of Portland cement, two parts of sand, and four and a-half of stone broken to a 2½ gauge, mixed by hand. The linings and faces of the tunnels are of granite. The down-stream part of the weir is built of granite blocks, in courses ranging from 15in. to 30in. in the tail wall, and above in steps with a uniform rise of 24in. The first eight steps from the tail wall are each 2ft. wide on the tread, while those above are respectively 2ft. 3in., 2ft. 6in., 3ft., and 3ft. 6in. The stones in each course underlie the others 18in., and are cheeked in 1in. The granite had to be carted a distance of fifteen miles over very hard roads. The face of the concrete work in the main body of the structure is rendered with a thick coating of cement mortar.

The waterway in the upper portion of the weir is occupied by twenty-one flood-gates, each having a clear opening of 20ft., and a vertical depth of 10ft. These, when required for the escape of flood-water, can be lowered into recesses in the body of the structure, and can be adjusted so as maintain the water level at the off-takes at the normal level. The frames of the gates are rolled T-iron beams, having 7in. section in the tables, with ¾in. web. They are 13in. deep at the centre, curved to 8½in. at the ends. The frames are filled in with cast iron plates; each gate weighs seven tons. They are worked by screw gearing, carried on the gangway of the bridging, and actuated by three 30½in. Leffel turbines. The turbines can be worked together or separately, and any or all of them can be brought into gear with any of the gates. The head available for working the turbines varies from 3ft. to 13ft., giving 3-horse power, with 78 revolutions per minute, to 27-horse-power, with 163 revolutions. Hand gearing to each gate is also provided in case of accident. For the purpose of working the gates in case of sudden floods coming during the night, an electric plant of five arc lamps, each of 2000 candle power, has been provided. The dynamos are worked by a 23in. turbine.

Immediately in connection with the weir are two regulators for the channel off-takes, one on the western, another on the eastern side. The western regulator has fourteen and the other four gates, each having an opening 10ft. wide and 7ft. high. These gates are of the vertical centre-pin type, of iron frames, filled in with timber sheeting. The quantity of excavation and materials used were:—

| | | |
|---|---|---|
| Excavation .. .. .. .. .. .. .. .. | 120,539 | cubic yards. |
| Granite masonry .. .. .. .. .. .. .. | 72,016 | ,, feet. |
| Cement concrete .. .. .. .. .. .. .. | 15,276 | ,, yards. |
| Pitching and rubble masonry .. .. .. | 671 | ,, ,, |
| Cast iron .. .. .. .. .. .. .. .. | 442 | tons. |
| Wrought iron and steel .. .. .. .. .. | 175 | ,, |
| Gun-metal and brass .. .. .. .. .. | 23,474 | lbs. |
| Timber .. .. .. .. .. .. .. .. .. | 1,839 | cubic feet. |

The cost has been as follows:—

| | £ |
|---|---|
| The Goulburn Weir .. .. .. .. .. .. .. .. .. | 106,262 |
| Land and compensation .. .. .. .. .. .. .. .. | 116,000 |
| Engineering and supervision .. .. .. .. .. .. .. | 7,226 |
| | 229,488 |
| Western Channel Works, including land and all other expenses .. .. .. .. .. .. .. .. .. | 217,995 |
| | 447,483 |

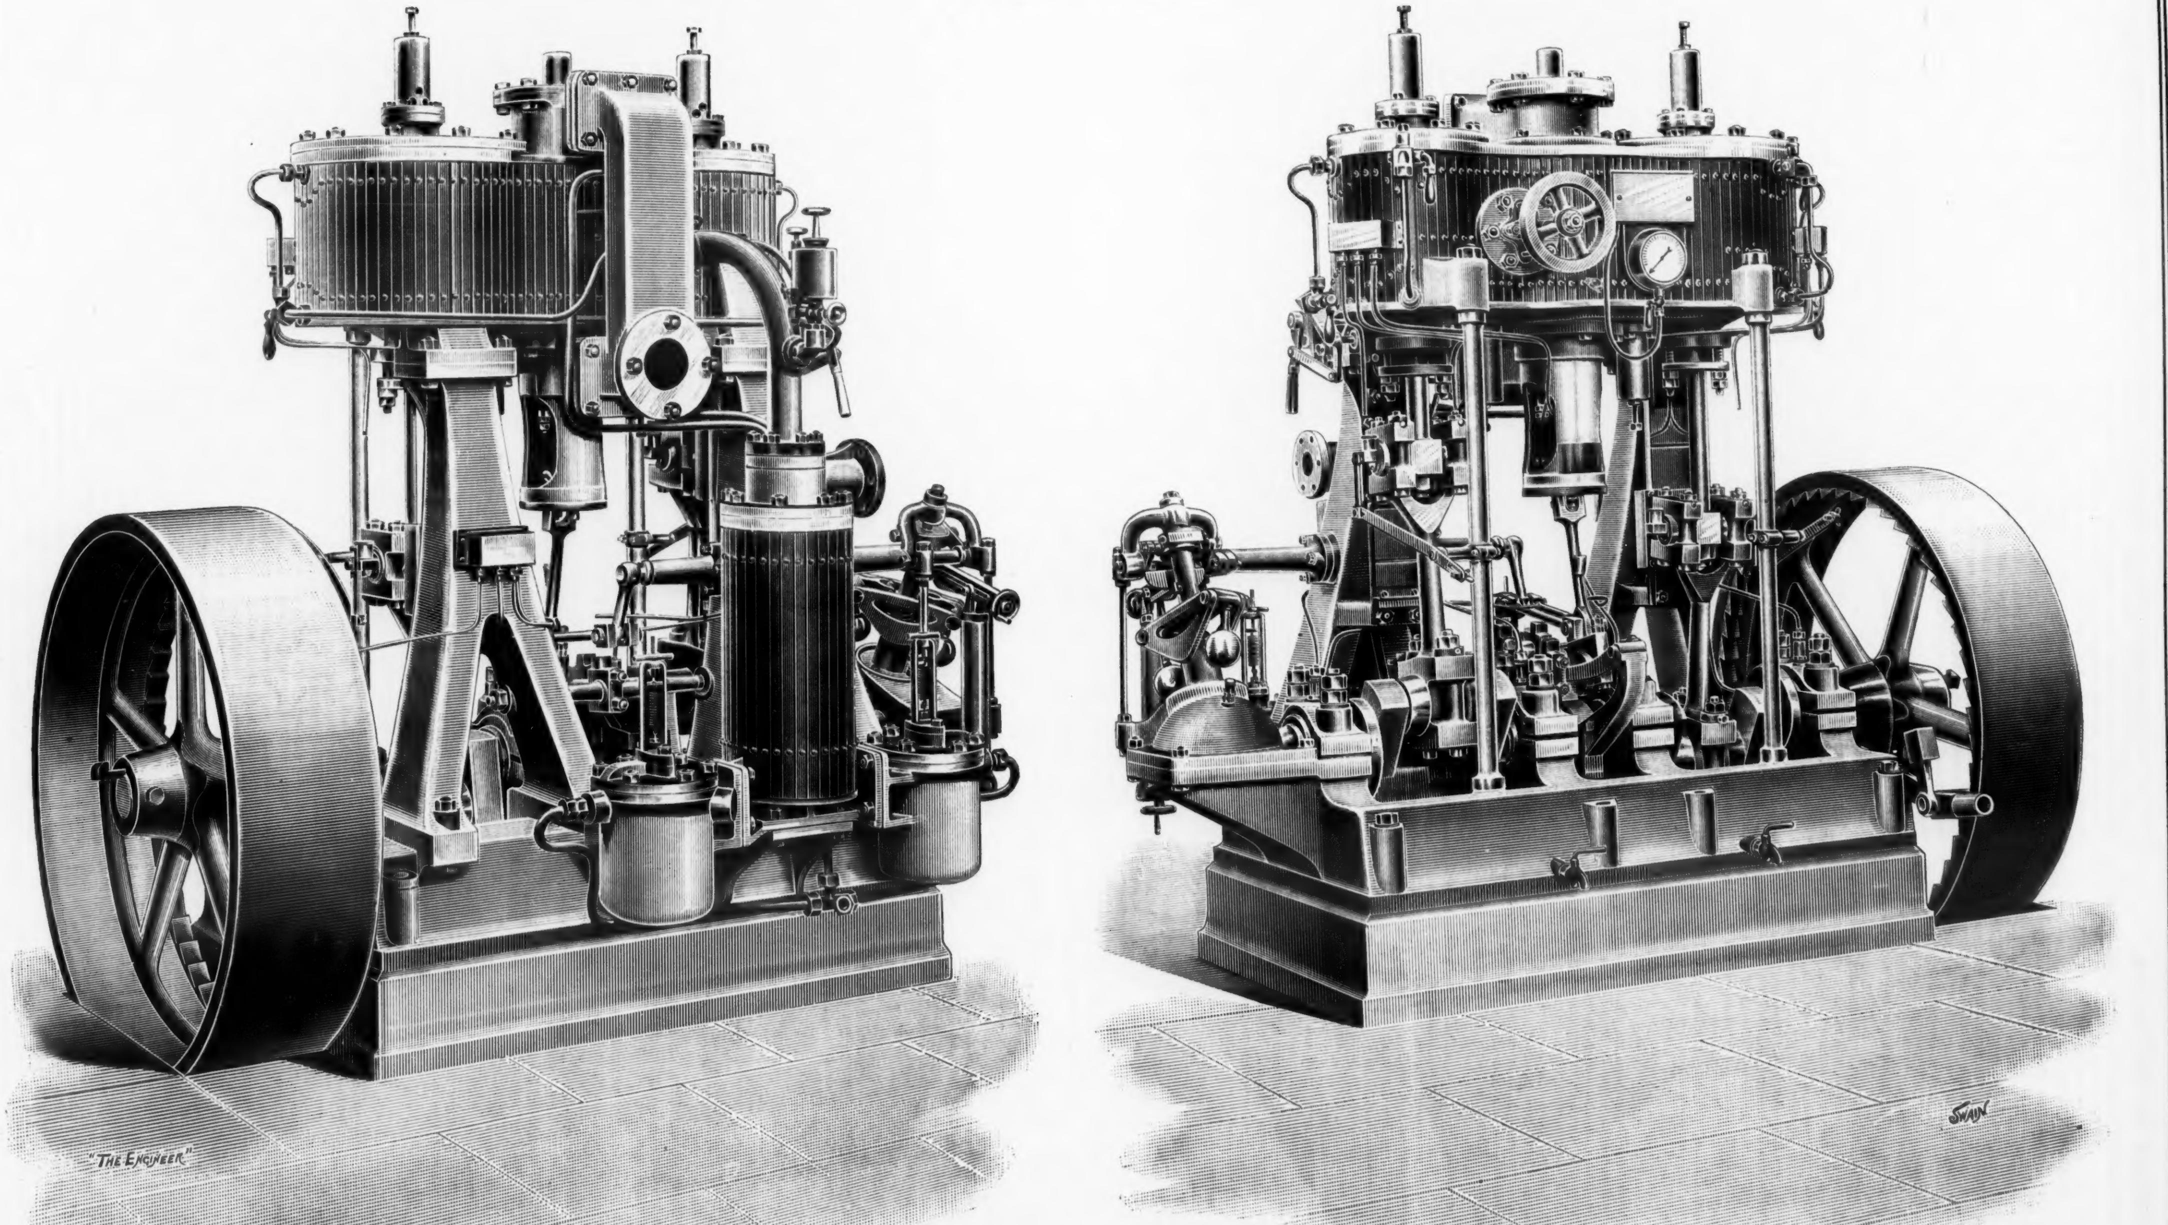
The distributing works on the western side consist of 19½ miles of channel, having a bed width of 110ft. and a depth at full supply of 7ft. The side slopes in cutting are 1½ to 1, and in embankment 2 to 1, with a berm of 5ft. at the set-off of the bank. The minimum height of the embankments is 2½ft. above full supply level, and the minimum crest width 15ft. The new grade is 6in. a mile, and the computed discharge 103,000 cubic feet per minute. The channel on the east side of the river has not yet been constructed.

The report is accompanied by twenty-seven illustrations, from which have been selected one showing—Fig. 1, an elevation of the weir; Fig. 2, plan of the weir; Fig. 3, the turbine wells and turbines; Fig. 4, the tunnel and flood-gate chambers.

HIGH-SPEED ENGINE FOR ELECTRIC LIGHTING

MESSRS. HALL-BROWN, BUTTERY AND CO, GOVAN, GLASGOW, ENGINEERS

(*For description see page* 102)



"THE ENGINEER"

## LETTERS TO THE EDITOR.

(*We do not hold ourselves responsible for the opinions of our correspondents.*)

### MARINE BOILER PRACTICE.

Sir,—When forced draught was first introduced, I read a paper upon the subject, and pointed out the danger and defects of such a system for marine boilers. I have now brought to a conclusion a long series of experiments commenced in 1886, the object of which was to determine the best modes for accelerating the steaming of marine boilers. A few remarks and figures on the subject may be of interest to your readers.

It was necessary to try the various classes of boilers in general use in order to ascertain what was due to construction and what was due to working and management. It soon became evident that however good a boiler might be, much depended upon the system or mode of working it to secure success.

When high authorities lead the van it takes time to arrest the progress of error. Endeavours are made to work boilers upon the cupola or iron-melting system, as in foundries where concentration of heat is required. No such action is safe in marine boiler practice. The blasting process simply converts the furnace into a battery, and the tube-plate into a target to receive the full force of its fire and of the heat generated. No boiler can stand this process long. It is due to the command of good materials for boiler-making that more accidents do not occur; as it is they are frequent enough.

Naval ships are full of delicate machinery. The process employed for working the furnaces causes the decks to become covered with dust and grit, and renders the boiler-room a pandemonium. I do not hesitate to say that a third of the coal is wasted. The error of the system has called forth remedies to mitigate the evils produced. Ferrules are placed in the tubes as fenders to ward off the heat, these in turn reduce the area for draught and the power of the boiler considerably; the fans have to run at increased speed in consequence. It is considered by some that marine boilers cannot be driven at a high speed without forcing, yet we have the loco practice in evidence against this idea. The loco class of boiler is now much used for marine purposes. I have tested them severely. I know of no water-tube or other class of boiler that will equal them for efficiency if treated properly, and allowed to work loco fashion.

An ordinary marine boiler I experimented with stood the highest test possible. High rates had no evil effects upon it whatever. The draught was increased until the coals were lifted from the grate. Coals were burned as fast as they could be put on as a crucial test. A similar trial was made with a loco class of boiler, and from close observation it appeared that the greater the speed the greater the immunity from harm to tubes and tube plates. A furnace working with a partial vacuum and others working with a plenum will bear no comparison. I am unable to send all the results of the various trials, as they are too voluminous. The Admiralty experiments were simply carried out to ascertain the difference between forced and induced draught under the same conditions. The Gossamer's forward boilers were fitted with induced draught. The following tables will give the results:—

*Experiments at Portsmouth Dockyard with Boiler ex H.M.S. Polyphemus.*

| Date of trial. | Description of trial. | Duration of trial. | Average pressure of steam. | Temperature. | | Revolutions of fan. | Total coals consumed in lbs. | Total water evaporated in lbs. | Lbs of water evaporated per lb. of coal. | | Lbs. of coal consumed per sq. ft. of grate per hour. | Water evaporated per sq. foot of grate per hour. | | I.H.P. Approximate. | Lbs of ashes. | Lbs. of clinkers |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | | | | Feed | Atmosphere. | | | | At actual temperature. | At 212 deg | | At actual temp're | At 212 deg. | | | |
| 1890 Aug. 5 to 9 | Induced draught | 96 hrs. | 74·2 | 62 | 69·9 | 485 | 80,600 | 777,044 | 9·64 | 11·13 | 40·4 | 389·6 | 450·37 | 423 | 3628 | 1202 |
| Oct. 28 to Nov. 1 | Forced draught | 93 hrs. | 77·3 | 51 | 49·8 | 372 | 94,500 | 759,338 | 8·03 | 9·3 | 47·3 | 381 | 444 | 395 | 3804 | 1807 |

Length of tubes between tube-plates, 8ft. 6in. Number of tubes, 258. Diameter, 1⅜in. outside. Area of fire-grates, 20·77 square feet. I.H.P. of fan engine, 1·38 per cent. of power produced.

In this case both series of experiments were conducted on the same boiler, the induced draught installation being dismantled after trial and substituted by the forced draught system.

*Experiments at Chatham with Boilers on Board H.M.S. Gossamer.*

| " 22 and 23 | Induced draught | 24 | 1000 | 1004·04 | Two forward boilers, fitted with Martin's patent doors. | 410 | 426 | 12·709 | 79 | 1·60 |
| " 27 | Forced draught | 6 | 1000 | | Trial abandoned on account of priming. | | | | | |

Grate surface, 143·32 square feet. Tube surface, 5722 square feet. No. of tubes, 1728. Length, 7ft. 1½in. Diameter, 1½in.

These trials were made with the ship moored in the basin for the convenience of registering results. The boilers were originally arranged for forced draught. The tube ends were reduced to allow more water against the tube-plate; this also reduced the steaming one-third, so that the maximum induced draught rates could not be developed. The test lay between the two systems of draught. A sea trial of about ten days full speed was also made on the annual manœuvres. The following is an extract from the Commander's report:—

"The stokeholds are open, in consequence of which there is a free exit for men in case of emergency, and the firemen can work more efficiently and with less discomfort and exhaustion than with closed stokeholds. From personal experience of the closed and open stokeholds, there is, in my opinion, absolutely no comparison between the two systems in this respect, for while with induced draught the stokehold is perfectly light and well ventilated, with forced draught quite the reverse is the case, and a large amount of coal dust is constantly blown about, causing great discomfort to the men. The combustion is more perfect, as evidenced by the very small amount of smoke emitted from the funnel, which also remained comparatively cool, whereas the forced draught funnel under an equal air pressure emitted large quantities of smoke and turned black from the heat, both being painted in the same manner. A sudden increase of speed can be more readily obtained, as the fans are always running and there is no necesity to close stokeholds. I have failed to discover any compensating advantage whatever attached to the forced draught system."

All the boilers were fitted with tubes with their ends reduced and ferruled, so that the area for draught was reduced to about half the ordinary tube area. The table will show that it was not possible to steam at high speed with forced draught, and the last trial had to be abandoned. The full power of the induced draught was not developed. The boilers would require re-tubing with parallel tubes before they would steam up to the ship's rated power. It was common, on the forced draught trials, for the funnel to get very hot and the flames to issue from the top—a very serious defect for war vessels. Ample means were provided for observation on the induced draught boilers on board the Gossamer. As a rule, the flames terminated with the tubes. On charging the furnaces a momentary flame might reach the fans, but the temperature would range from 450 deg. to 500 deg., showing that it is possible to absorb all the heat on the heating surfaces. There are several things requiring attention for high rates of steaming, such as the disposition of the feed-water, the arrangement of the furnaces, &c., which, as a rule, are much neglected. W. A. Martin.

Pocock-street, Blackfriars-road, London, S.E.
August 1st.

### THE EIGHT HOURS' DAY IN PORTSMOUTH DOCKYARD.

Sir,—It may interest some of your readers to know that much dissatisfaction is being expressed in the dockyard concerning the working of the eight hours' day. The men find that they really have to work all their time in the yard. Much of the idling has been stopped, and it is probable that more work is being turned out per man than ever before. This does not suit the dockyard matey at all.

Again, there is trouble because of the new examination system. Apprentices, before being admitted, have to pass an examination in arithmetic, &c. &c. This examination has hitherto been carried out by the chaplain without fee of any kind, and favour has always been shown to the sons of dockyard hands.

Some of the progressive agitators, hating the Church and its works, insisted that the chaplain examination should be abolished, and that the work should be done by the Civil Service Commissioners. The Admiralty conceded the point, and the result is that instead of about 90 per cent. of the candidates passed being the sons of dockyard hands, not 10 per cent. are such, and the promoters of the change have a very bad time in store for them.

Portsmouth, July 31st. Keppel.

### THE PATENT AGENTS' REGISTRATION BILL.

Sir,—The Patent Agents' Registration Bill as amended by the Select Committee contains provisions which will entitle certain persons to be placed on the register without undergoing examination at any time prior to 1896, and also provides that the register shall be kept in the form given in the schedule, which form contains a column in which an indication is to be given of the date of *first* registration, but does not provide for an unmistakeable indication being given of those registered persons who have been duly examined as to their knowledge of patent law and practice. This, I venture to suggest, is unfortunate for the public and for those who become entitled to registration by examination. Those who have already passed, and those who pass and are registered prior to 1896, are in an even worse position than those who are registered subsequent to that date, since, as regards the latter, the date of registration is an indication that they have passed the examination. This defect should, I suggest, be remedied by providing another column in the register in which the date of passing the examination should be given. A Successful Candidate.

August 2nd.

### LIGHT RAILWAYS IN ENGLAND.

Sir,—I read with much interest your descriptions of the Eyemouth Railway and of another local light railway in Hampshire, and wish to express my strong approval of the sentiments expressed in your closing remarks on the former line, which I quote, as follows:—"If people were half as ready to develope industries of this kind through responsible engineers, as they now are—aided by non-technical company promoters and inside and outside brokers—to float rash speculations headed by those retired from all sorts of official positions, we should hear less of total loss of fortune on the part of investors, and nothing of the distress and poverty of the outlying fishing districts in remote parts of our coasts."

I have again and again urged that there is a field for light railway development in England, if conducted on proper and economic principles, and though some years ago you severely "jumped upon" certain opinions which I had expressed in this matter, it is encouraging to read your appreciation of such a work carried into execution. Ireland probably has several places awaiting an opening-up of this kind. In this connection it is appropriate to call attention to the advantages offered by electric railways, built upon their own land like ordinary railways. The greatly reduced weight of the motor cars from that of steam locomotives enables a very much lighter type of substructure to be safely and properly adopted, and the power plant can be made available for other uses, while in many cases it is probable that water power would be available to drive the generating plant. One such railway here is three miles long, connecting a small manufacturing town with the main line railway, and carrying freight and passengers. It has two passenger cars with motors, two trail cars for passengers, and two cars for baggage and express—parcels—traffic. Coal and freight cars from the main line are hauled by a ten-ton electric locomotive, which can haul four loaded cars up a grade of 1 in 20. The power plant consists of a 150-horse power water wheel, with a steam engine in reserve.

In regard to your remarks as to the unfortunate readiness of investors "to float rash speculations," it may be noted that a company is reported as being organised here to manufacture and operate palace cars, and an English broker or promoter is reported as saying that the bonds can be floated in England if "properly promoted." It is easy to build such cars, if money is forthcoming, but quite another thing to operate them. Practically all important lines have contracts with the existing Pullman Company or Wagner Company, and these two companies have absorbed the few smaller companies, such as the Mann, Woodruff, &c. The contracts between the railway and palace car companies usually provide for the exclusive use of the latter's sleeping cars, &c., and it would be well for prospective investors, charmed by the tales of the wealth of the Pullman Company, to make some inquiries as to the probabilities of their cars, if built, being enabled to run on any railway.

New York, July 20th, E. E. Russell Tratman, C.E.

### INDIAN RAILWAYS.

Sir,—I have read with interest the letters you have published bearing upon the working of the Indian railways. Manufacturers who have been in the habit of supplying their goods to these lines of railway have felt and are feeling the keenness of competition from firms of quite indifferent standing, whose goods are freely shipped. I am quite prepared to have the question asked by the engineers whether or no competition should be limited, and I say by all means yes. Buying in the cheapest markets does not necessarily mean that the lines are kept in the highest state of efficiency. Again, a very unfair means of doing business has crept up on this side, and that is railway companies giving their orders to middlemen who are quite ignorant in many cases of the goods they supply, their object being simply to get the orders and sweat the manufacturers. By this means the quality of the goods supplied invariably suffers. In many cases the railways and engineers think they are getting a cheaper article—on paper yes, but in practice no. I would suggest the Indian Government dividing the practical monopoly which exists, *i.e.*, amongst the engineers on this side. In these democratic days one cannot expect business without competition, which I venture to think is being considerably overdone, especially in the branches of soft goods and hardware; economy by all means, but not at the expense of efficiency. I should think the India-office, in which is included the management on this side of the railways, could be worked at half the present expense and with equal efficiency. Merchant.

Glasgow, July 31st.

### THE MORALITY OF DIAMOND MAKING.

Sir,—We read in the scientific journals much about attempts to make diamonds, in relation to the work of Moissan and others, but has it occurred to anyone that a practical method may already have been discovered? In such case what would be gained by publication but severe injury to individuals and to South Africa? Patenting would be of no use, as the patent would be infringed in a wholesale manner. Working it avowedly as a secret process would not answer; the operators would be likely to disappear mysteriously. Can any of your readers throw light upon the solution of the problem "What should he do with it?" considered in its moral and material aspects. W. H. H.

## HIGH SPEED ENGINE FOR ELECTRIC LIGHT.

Our illustration (p. 101) is from photographs of front and back views of an engine constructed by Messrs. Hall-Brown, Buttery, and Co., of Helen-street Engine Works, Govan, Glasgow, from the patented design of Mr. E. Hall-Brown, for the electric light installation at the Northern Co-operative Stores, Aberdeen. The installation is under the superintendence of Professor A. B. W. Kennedy, of London. The engine, which is of the automatic expansion double-acting type, with cranks set at 180 deg., has several points of interest. The cylinders are cast in one piece, with a central casing for a piston valve, which in this case is actuated by a Finck's link gear, controlled directly by a high speed spring governor of the Wilson-Hartnell type. Although in this case Finck's link has been adopted, the makers also make an arrangement with a modified Hackworth gear, and for engines with a throttle valve governor a single excentric serves to distribute the steam to both cylinders.

The specification for this engine stipulates that the governing shall be equally perfect at the normal speed—in this case 225 revolutions—and at 20 per cent. above the normal speed.

In order to fulfil this condition the governor has been arranged with a supplementary spring acting upon an adjustable lever, the load upon the spring being also adjustable by means of a screw and hand wheel; by this means the governor can be accurately adjusted to the highest degree of sensitiveness possible without hunting. In order to have the governor acting as directly as possible upon the valve gear, it has been placed at an angle, and is connected by means of a single lever with the valve gear shaft. This arrangement can be plainly seen by comparing the front and back views of the engine. The makers usually fit balanced cranks to their high-speed engines, but in this case, as the speed of revolution was comparatively low, these were dispensed with. The cylinders rest upon wrought steel columns in front, and cast iron columns of inverted Y section at the back; this design, while being pleasing to the eye, make a very rigid engine entirely free from any motion of the cylinders. At the back of the engine the steam separator and steam traps are placed. These steam traps are one of the makers' specialities, and have, we understand, given complete satisfaction. The exhaust from the low-pressure cylinder is carried off from the ends by a separate pipe at the back of the engine, and is prevented from coming into contact with the cylinder body at any part. The crank pins are lubricated by means of centrifugal lubricators, and are supplied with oil, together with all the other joints upon the engine, from boxes placed upon the cylinder and columns. The bearing surfaces throughout are exceptionally large, and ample provision is everywhere made for efficient lubrication during long runs. Every bearing and slide upon the engine is adjustable, and all nuts are efficiently locked by means of set screws or double nuts. The governor is driven from the crank shaft by means of machine-cut bevel wheels running in a bath of oil. The barring gear consists of a ratchet-and-pawl arrangement, with which the engine is easily started from any position. Throughout the whole engine the workmanship and material are of the highest class, and on trial the engine, we understand, worked with smoothness and steadiness. The dimensions of the engine shown are:—Cylinders, 9in. and 15in. by 9in. stroke; 50 indicated horse-power at 225 revolutions, with a steam pressure of 120 lb.

## RAILWAY MATTERS.

The penny-in-the-slot system of selling tickets has been adopted by the North London Railway. The arrangement is for workmen's tickets only.

The battle of the routes still continues in Ceylon with regard to the proposed Indo-Ceylon railway scheme. The authorities favour the Karunegalu extension, although a direct seaside route appears to have advantages.

News from St. Petersburg says, according to the Vienna correspondent of the *Standard*, that the railway from the Caspian Sea *viâ* Aschabad to Samarcand is to be extended from this last place to a point as near as possible to the Indian frontier.

The railway bridge at Washburn, Wisconsin, belonging to the Omaha lines, on Monday last caught fire owing to a forest fire. Soon afterwards a freight train ran on to the bridge, which at once collapsed. The engine and sixteen cars were destroyed.

Cardiff railway station is about to be largely improved. There is to be a new down platform, on which suitable structures will be erected for the convenience of passengers; the platform itself will be covered with light glazed roofs, and connected with the opposite side by means of a subway.

Judgment has at length been delivered in the appeal of the London Street Tramways Company by the House of Lords. It confirms the decision of the Court below, and dismisses the appeal with costs. Lord Ashbourne alone expressed an opinion that the appeal should be allowed.

A new fare-registering punch has been devised by Mr. F. Bracebridge-Mills, of Hatton-garden. It is of convenient size, its most salient advantages being self-adjustment, avoidance of calculation and simplicity, there being only one thumb-lever, one ticket slot, and one perforating punch.

The Brazilian Railway branching off from Santa Maria northwards, to ultimately connect with the State of San Paulo, has so far progressed as regards the section in the State of Rio Grande do Sul, that it has been of some use to the Government for moving troops, the permanent way being completed to Villa Rica, a distance of 48½ miles.

The Chignecto Ship Railway Co. have asked the Canadian Government for an extension of time in which to complete the works in order to enable the company to earn the Dominion subsidy of a quarter of a million dollars for twenty years. Three million dollars have already been spent on the railway, which is in Nova Scotia.

A goods train conveying iron plates for H.M.S. Renown, now building at Pembroke, ran off the line on Monday at Lamphey, near Pembroke. Workmen and cranes had to be brought from Pembroke to clear the line, which was completely blocked by the large plates. Considerable difficulty was experienced in removing them, owing to their great weight. The traffic between Tenby and Whitland was seriously interfered with, as the engines were blocked at the Pembroke end of the line.

The Isle of Man Tramways and Electric Power Company has completed its tramway between Douglas and Laxey, a distance of eight miles, and on Saturday last an electric car was run through. Dr. Hopkinson, who is a director of the company, had charge of the trial, which was quite successful, the car running the whole distance without a hitch. The second journey was made entirely with power supplied from one of the accumulating stations.

The Railway between Thessalonica and Monastir, a portion of which has been in operation since 1892, is now open for traffic. The line between Monastir and Vertekop was very expensive to make, there being fifteen tunnels. The rolling stock has been chiefly supplied by the Deutz, Dusseldorf and Eszlingen Works, the Maschinenbau-Anstalt of which latter town has obtained an order for ten locomotives for the South African Railway, while the Bochumer Verein has booked 7000 tons of rails for the same line.

The railway which will connect the Port of Bizerta with Tunis by a branch from Djedeida—on the Medjerda main line railway system in Tunisia—has made considerable progress, having reached the town of Mater, about half-way between Bizerta and the new junction. The convention between the Bane-Guelma Railway Company and the Tunisian Government for the construction of the several lines connecting Kairwan, and the principal southern seaports with Tunis, is still wanting ratification by the French Parliament.

The Kurung railway bridge, on the N.W. State Railway, near Rawal Pindi, which consists of 150ft. spans, carried on stone piers 98ft. high, is remarkable, says *Indian Engineering*, both for design and method of construction. The staging used in erecting the girders consisted of four piles supporting light Warren girders, on which the platform was laid. The piles were hollow, and were constructed of twenty-four flange rails, arranged with the heads of the rails inside. These rails were bound together by flat iron bands placed 5ft. apart. The rails were arranged so as to break joint, short odd lengths being used at top and bottom. Successive lengths of rails were fished together in the ordinary way. The bracing between the piles also consisted of rails, all which have since been used on the permanent way.

Except two lines in progress, one to extend from Tsuruga by Kanagawa, into Etchin, and the other from Fuknshima on the main northern line, by Yonezawa and Akita to Awomori, there are no Government railways being made in that part of Japan east of the Biwa lake, but a fresh impulse has been given to the construction of private lines. The company owning the main line from Tokio to Awomori contemplates the construction of a line from Tokio through Mito to Sendai, and are considering the connection of Shimbashi Station, Tokio, with their terminus at Uyeno by a direct line across the city. A metropolitan line is being constructed to the centre of Tokio, near Uyeno. The connection of Nagoya with the Kansei Railway at Yokkaichi by a direct line across the Kisagawa, by the head of the Owari Gulf, which will afford an alternative and shorter route to Kioto, is being proceeded with.

The manufacturers of locomotives, carriages, and wagons suffer from the absence of new railway expenditure. At home the largest proportion of rolling stock is made in the railway workshops, whose capacity is much beyond the proper function of companies whose main duty is to carry traffic. Messrs. Matheson and Grant state in their last half-yearly Engineering and Iron Trades' Report that "In India, the Colonies, and South America, not only are much needed extensions of existing lines postponed, but the severest economy is also being practised in regard to renewals. It is scant comfort to manufacturers to know that the reaction, when it comes, will be the more active because of present abstention. The organisation and plant of engine and carriage builders cannot with advantage be applied to other engineering manufactures, and slack times in their one industry hit them hard in consequence. Locomotive builders make tramway engines, and carriage builders make tramcars, but there is not much doing in either. The makers of little locomotives have more orders and inquiries than at the beginning of the year, but factories are not yet half employed. The approaching sale of the plant used in the construction of the Manchester Ship Canal will release and render available a large number of second-hand engines of the kind used by contractors, but it is doubtful economy to purchase these for anything but a short term of working.

## NOTES AND MEMORANDA.

On July 30th the heat in New York reached 105 deg. in the shade. Before 2 o'clock thirty-three cases of sunstroke were reported.

Some twelve to seventeen tons of ice, or its equivalent in cold air or cooled water can now be produced per ton of coal by some of the ammonia and other chemical refrigerating systems.

The fact is interesting from a mechanical engineering and animal mechanics point of view, that Shorland, the cyclist, in the twenty-four hours' race on the Herne Hill track on Saturday last, rode 460 miles 1286 yards, which means an average speed of 19·2 miles per hour for the whole of the twenty-four hours.

In the Presidency of Bengal saltpetre is manufactured in the Patna and Bhagulpore divisions, and in the city of Calcutta and its suburbs. Besides this, a considerable quantity comes down from the North-West Provinces and the Punjab. The total exports in 1892-93 amounted to 438,408 cwt., valued at Rs. 43,36,588.

According to some comparative researches on the products of the combustion of lighting gas given by an Argand burner and an Auer burner, by M. N. Gréhant, the combustion products from the Auer burner yielded evidence of the presence of carbonic oxide to the extent of 1 in 2580, those from the Argand burner a trace only, estimated at 1 in 75,000.

The production of platinum is increasing in the United States. The nickel ore from Copper Cliff, near Sudbury, contains 0·20 per cent. of plantinum, and similar ores have been observed at Denison, Ontario, containing from traces to 0·53 per cent. of platinum. A recent discovery of platinum ores on the river Tulamee, in British Columbia, appears to be of even greater importance.

At a recent meeting of the Paris Academy of Sciences, M. Georges Charpy read a paper on the relation between the density of a saline solution and the molecular weight of the dissolved salt. According to *Nature*, the density of a saline solution augments proportionally to the molecular concentration if it be admitted that the molecular weight of water at 0 deg. is about 3 × 18. The densities of equally concentrated solutions of analogous salts are nearly proportional to their molecular weights.

The following method of purifying water by means of alum is employed in a number of towns in the United States. The alum forms a kind of jelly, which retains the micro-organisms existing in the water, and carries them down to the bottom of the filter. It is necessary to be very careful in using it—an excess causing the mixture to pass through unaffected—the water instead becoming strongly charged with alum. The requisite quantity of course depends on the quality of the water. It is estimated at 15 grammes to 10 litres of water.

It is stated that by a new German process steel tubes for boiler work are punched from the hot metal. A bar of steel is placed in a matrix of sufficient strength, and having a hole the exact diameter of the tube; then, without allowing time for the steel to cool, a mandrel having a rounded end is forced lengthwise into the mass. The *American Manufacturer* says tubes nearly 8in. in diameter are thus produced, the pressure required to operate the mandrel being 180 tons. The tube is finished by drawing and redrawing to the required thickness.

During the month of June the rainfall at Oxford, representing the mean fall in the Thames valley, has shown an excess of 0·58in.—the only important excess since July, 1893—in which month there was an excessive rainfall, the quantity above the twenty-five years' mean being 1·12in. The only other similar instances since then were in October, 1893, when there was a surplus of 0·09in., and in March, 1894, when the excess was 0·08in. There is this peculiarity in the rainfall of the present June: Of the 2·79in. of rain that fell, 2·56in. came down during the first half of the month—as much as 0·99in. falling on one day, the 4th; whilst only 0·23in. fell during the second half of the month.

In a recent number of the *Comptes Rendus* is a paper on "The Calorific Radiations included in the Luminous Part of the Spectrum," by M. Aymonnet. The following conclusions are deduced from a study of the spectra given by the Bourbouze and Drummond lamps and by the sun:—(1) The eye does not perceive all the radiations between the red and violet; (2) the eye is not acted on by rays intercepted by water; (3) when the medium between the radiant source and the measuring apparatus contains water, there is an imperfect concordance between the distribution of heat and that of light in the same region of the spectrum; (4) the bright lines or bands which we can observe in a spectrum are only those or a part of those which pass through water.

In Upper Silesia a borehole has been carried to a depth of 6700ft.—over a mile and a quarter—although the diameter of the tube—a Mannesmann—is fully 2in. at the bottom, and it is expected that an additional depth of nearly a quarter of a mile will yet be reached. The *South African Mining Journal* says that strata at 17ft. depth show a constant temperature of 51 deg. Fah., with an increase of 1 deg. Fah. for 55ft. of descent until something like 1800ft. is reached, when the temperature increases by 1 deg. Fah. for every further 44ft. of depth. If the increase of temperature goes on increasing at the same ratio, the temperature at the bottom of the projected boring in Silesia may be expected to be found to be very nearly 100 deg. Fah. The result of the experiment will be of interest especially to mining engineers.

The world's production of silver amounted to 2,592,000 kilos. in 1881, and remained stationary until about 1887. Since then the production of silver has increased at an enormous rate on account of the discovery of the rich deposits in the Sierra Mojada, Colorado, and Montana, and rose to 4,479,000 kilos. in 1891, and 5,935,000 kilos. in 1892. On the other hand, the production of gold, which in 1881 amounted to 158,000 kilos., remained stationary until 1888. Then it increased, through the opening of the South African goldfields to 192,000 kilos. in 1892. The *Journal* of the Society of Chemical Industry says that part of this increase is due to the extraction of gold from American silver ores. The silver output of America alone amounted to 692,000 kilos. in 1872, 1,240,000 kilos. in 1885, and 2,018,000 kilos. in 1892. The relation between the price of gold and silver was 1 : 15·56 in 1870, 1 : 18 in 1880, and 1 : 22 in 1890, and, in spite of the Sherman Bill, came to 1 : 23·73 in 1893.

At a recent meeting of the Berlin Physical Society Dr. H. du Bois spoke on the changes of resistance of a bismuth spiral in a powerful magnetic field. This change, discovered by Lord Kelvin, had been measured in the case of bismuth in a magnetic field whose maximum strength was 12,000 C.G.S., and the curve of resistance in the field, compared with that of the resistance outside the field, was found to be at first concave upwards and then straight. The resistance in the field of maximum strength was 1·7 of that in zero field. The speaker, using some very powerful electro-magnets which he had recently exhibited to the Society, and which gave an intensity of 38,000 C.G.S., had, in conjunction with Dr. Henderson, measured the resistance of spirals of pure bismuth, and found that the curve pursues a further straight line course, so that the resistance in the field of greatest intensity is three times as great as in a field of zero intensity. The measurement of the resistances in a magnetic field at different temperatures had yielded interesting results. In weak fields a rise of temperature increased the resistance; in stronger fields the effect was less, and became zero in a field of 7000 C.G.S. In still stronger fields the resistance of the warm spiral was less than that of the cold. The experiments, *Nature* says, have so far been carried on only for temperatures between 0 deg. and 25 deg., but will be pushed further up to 100 deg.

## MISCELLANEA.

The erection of the Watkin Tower has been temporarily stopped for want of funds.

The 1895 meeting and exhibition of the Bath and West and Southern Counties Society will take place at Taunton.

An electric light is to be placed in the Fire Island lighthouse, off New York, the candle-power of which is estimated to be 450,000,000 candles.

The telegraphic line from Tati to Buluwayo, a distance of 108½ miles, has been constructed in the short time of 133 days at a cost of under £3400.

Experiments are to be made at the approaching German manœuvres with a pontoon made of aluminium. It is so light that it can easily be carried by three or four men.

Six months ago the Llanelly Pottery Company consented to the adoption of the eight-hour system in its works. The workmen have found the experiment a failure, and have asked for the resumption of the old system, which will accordingly be now reverted to.

The Ealing Electric Lighting Station will be put into operation the first week in September, and the town lighting commenced. A local exhibition illustrative of electrical developments and applications for lighting power and cooking will be opened in the middle of September.

In our account last week of the visits paid by the Leeds Association of Engineers to various works at Wakefield, we omitted to mention that the machinery particularly noticed at the boiler-making establishment of Messrs. Spurr, Inman, and Co. was made by Campbells and Hunter, Dolphin Foundry, Leeds.

The trial at Chatham of the new protected cruiser Forte, 10, 4360 tons, 7000-horse power, has been successful. At forced draught the engines develope a speed of 19½ knots. The armament of the Forte consists of a couple of 6in., four 7in., and nine smaller quick-firing guns. Her engines were made in Chatham dockyard.

The condition of the Gohna Lake is still giving anxiety, as the inflow continues to gain on the percolation. According to the latest reports, the surface of the lake is now 100ft. below the top of the dam. If no fresh landslip occurs, it is just a question whether the dam will hold out till the expiration of the rainy season.

Next spring we are to have the first of a series of exhibitions, under the direction of the London Exhibitions Limited, at Earl's Court. The Empire of India is selected to be the subject of the Company's initial venture. The Albert Palace and the Paris Hippodrome buildings will be re-erected in the grounds at Earl's Court. Mr. Imre Kiralfy is concerned.

Last week the French Parliament granted a sum of £4000 at the request of the Commissioner-in-Chief of the Exhibition of 1900. The money voted is for the purpose of defraying preliminary expenses incurred in the preparation and engraving of plans and drawings, and also to provide the necessary funds for paying the costs of the competition for designs which will shortly be inaugurated.

A large set of plant for electric transmission for a colliery, consisting of a dynamo to give 250 ampères at 600 volts at 400 revolutions, to work several motors for pumping and other purposes, is being made by Messrs. J. P. Hall and Company. The largest motor is to give 70 brake horse-power at about 900 yards from the surface. This is said to be the largest plant yet put down for this purpose.

The Chief Commissioner formally inaugurated the Rangoon High-pressure Water Supply Works last week. These have been completed in less than nine months. They draw water from the lowest level of the lakes, giving thereby 500,000,000 gallons additional supply, and averting the danger of a water famine. They also pump water up to Pagoda glacis, giving a much-needed additional pressure.

The Lambeth Board of Guardians have accepted the tenders of Messrs. Galloways and Mr. W. Neil for the new work at their Renfrew-road Workhouse, the former supplying the boilers and carrying out the engineer's work, the latter undertaking the new chimney shaft and builder's work. The consulting engineer, under whose specifications the work will be carried out, is Mr. E. H. G. Brewster, of Delahay-street, Westminster. The amount of the respective tenders was £1500 and £1906, making a total of £3406.

A sale of agricultural machinery and machinist plant, including ploughing tackle, two 16-horse power single-cylinder engines, by Fowler, with 5-furrow plough; 11-tine cultivator, sleeping van, water cart, &c., several portable engines, thrashing machine, straw elevators, workshop and machine tools, and some food-preparing machinery, by Mr. David Guy, will take place on the premises, Dicker, Hellingly, Sussex, about 2½ miles from Hailsham, on Thursday, August 9th. Catalogues at the East Sussex Auction Mart, Hailsham.

The canal on the Canadian side of the Sault Ste. Marie will be opened for traffic within a few weeks. Its total length is 18,100ft., of which 3500ft. is the distance across St. Mary's Island. The lock chamber is 900ft. in length, 60ft. in width, and the depth of water on the sills is 20ft. 3in. at low-water mark. The canal itself is 152ft. wide at the water line, and 145ft. wide at the bottom. According to *Engineering News* the first contracts for the work were let in 1889, and up to December 31st, 1893, the total amount expended had been 2,243,890 dols. Up to June 30th, 1893, the Dominion of Canada had expended a total of 71,310,793 dols. on its canals and had received from them a total revenue of 9,850,579 dols.

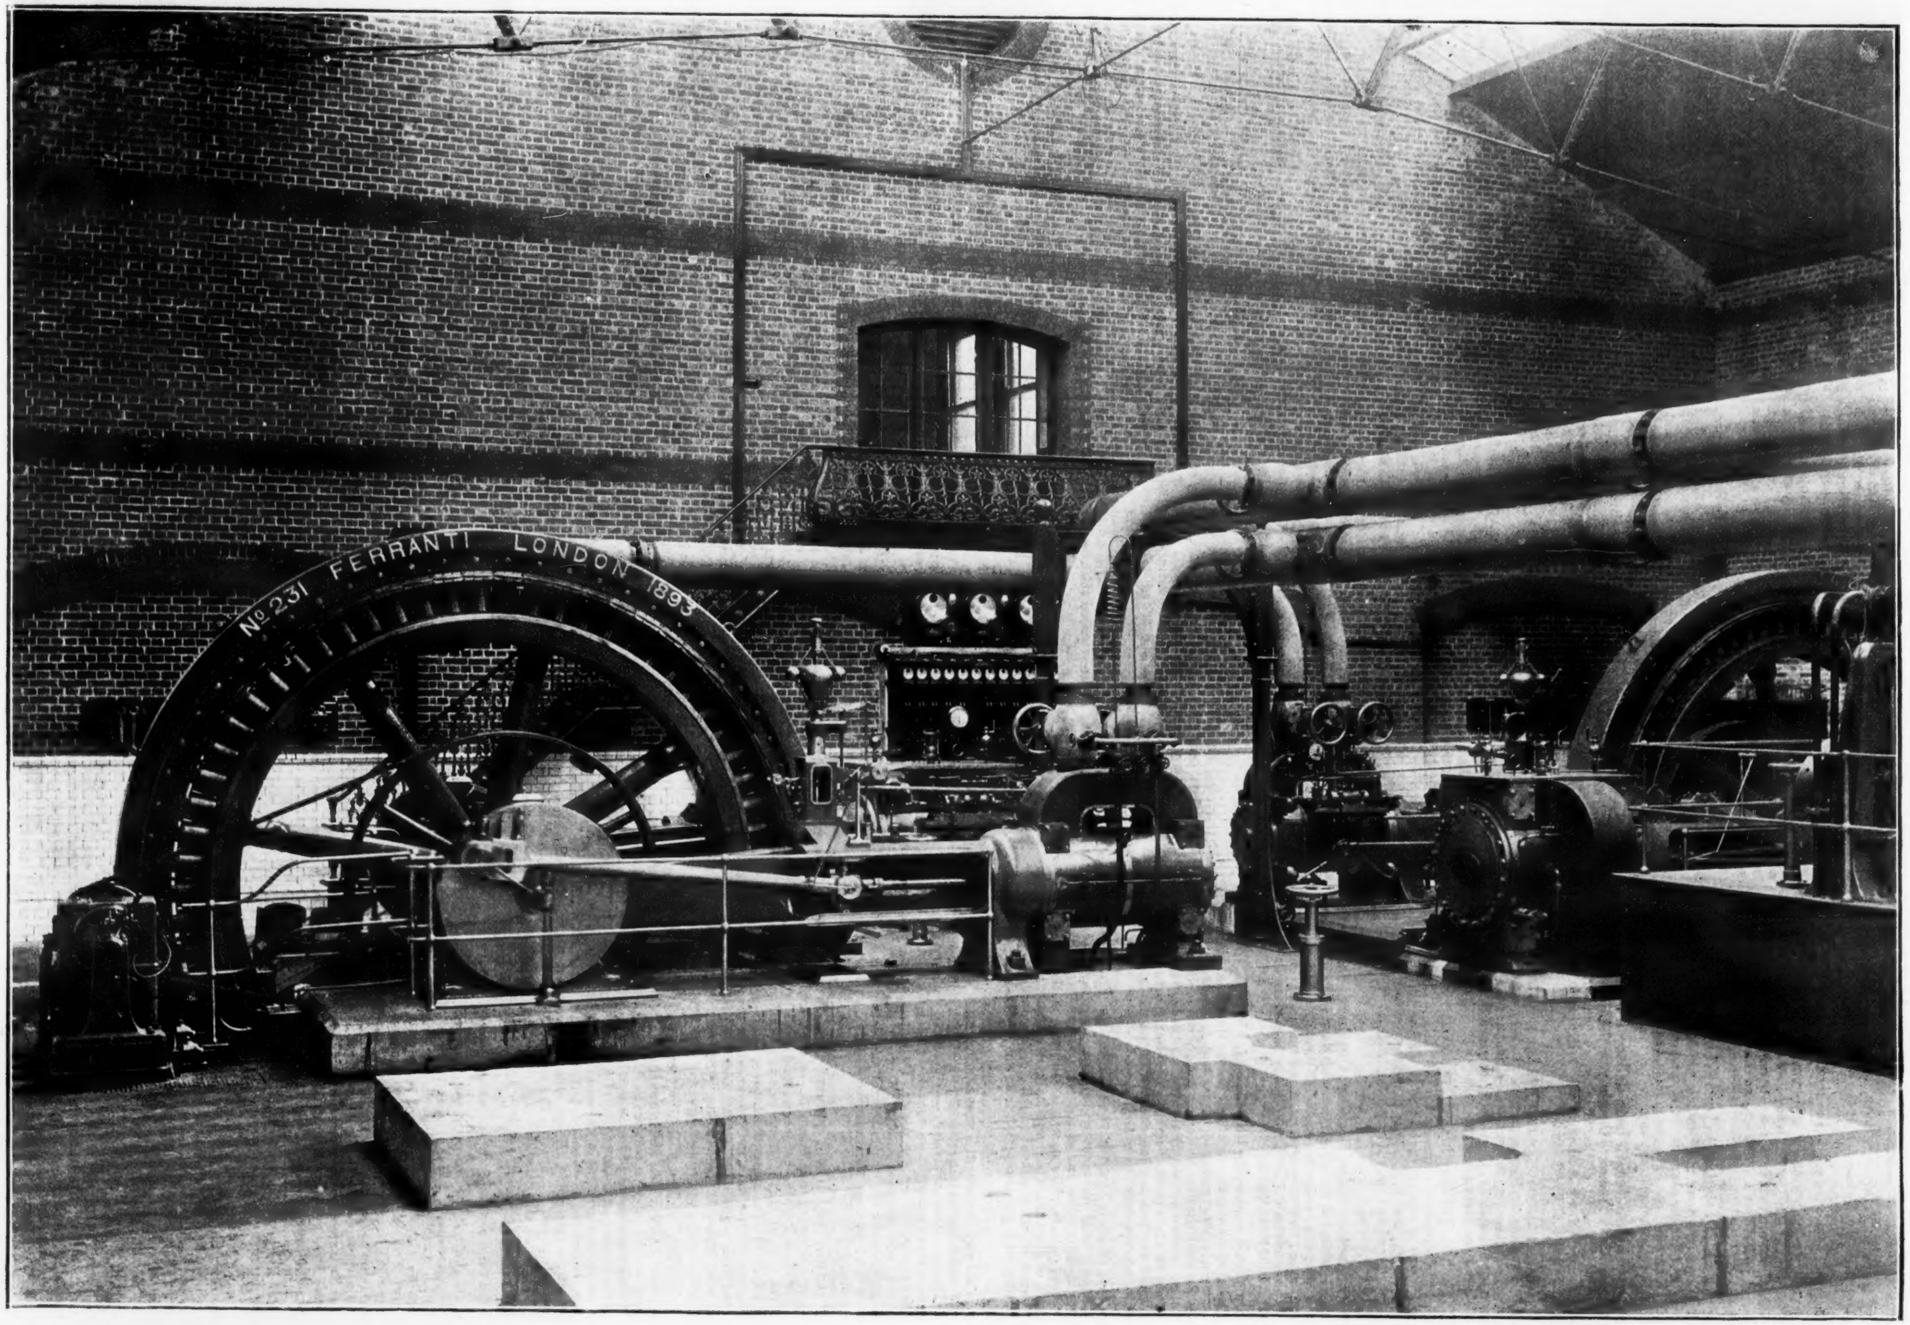
We have received the August number of the *Journal* of the National Lifeboat Institution, the principal feature of which is the wreck chart for the year 1892-3. By far the most wrecks have occurred on the East Coast—notably on the Norfolk and Suffolk Coast, and those of Northumberland and Durham, where the institution appears to have been especially busy. The localities of the various casualties, irrespective of collisions, were: East Coast of England, 547; North Coast, 367; West Coast of England and Scotland and East Coast of Ireland, 827; North Coast of Scotland, 114; East Coast of Scotland, 145; and other parts, 214; total, 2214, or 916 less than in the previous year. We may mention that the institution is in want of funds.

Matheson and Grant in their half-yearly Engineering Trades' Report say that notwithstanding the extreme cheapness of steel and the more than corresponding reduction in the prices of finished work, the leading firms are only partially employed, and in seeking profit from the manufacture they have often to undertake troublesome and risky erection *in situ* at home and abroad. According to the amount of repetition, bridges up to 200ft. span can be purchased at from £10 to £13 per ton, and roof structures at from £12 to £15 per ton. During the last half-year a considerable tonnage has been made for English railways at home; the bridges for the Manchester Ship Canal have been finished, but much further work in warehouses, wharfs, and other subsidiary structures will be needed. There has been a moderate export of bridges to India, China, and Japan. The principal railways at home are constantly extending and rebuilding their stations, and there is much strengthening and renewing of bridges.

THE PORTSMOUTH ELECTRIC SUPPLY WORKS—MACHINERY HALL

MESSRS. S. Z. DE FERRANTI AND CO., LONDON, ELECTRICAL ENGINEERS

(*For description see page* 107)



No. 231 FERRANTI LONDON 1893

## FOREIGN AGENTS FOR THE SALE OF THE ENGINEER

PARIS.—Boyveau and Chevillet, *Rue de la Banque.*
BERLIN.—Asher and Co., 5, *Unter den Linden.*
VIENNA.—Gerold and Co., *Booksellers.*
LEIPSIC.—A. Twietmeyer, *Bookseller.*
NEW YORK.—International News Company, 83 *and* 85, *Duane-street.*

## CONTENTS.

The Engineer, August 3rd, 1894.

International Navigation Congress .. 95
Institution of Mechanical Engineers .. 96
The Iron Trades Employers' Association .. 99
Electric Welding .. 99
Portsmouth Electric Supply Works. (Illustrated.) .. 99
The Goulburn River Weir, Victoria. (Illustrated.) .. 100
High-speed Engines for Electric Lighting .. 101
Letters to the Editor:—Marine Boiler Practice—The Eight Hours' Day in Portsmouth Dockyard—The Patent Agents' Registration Bill—Light Railways in England—Indian Railways—The Morality of Diamond Making .. 102
Railway Matters .. 103
Miscellanea .. 103
Notes and Memoranda .. 103
The Portsmouth Electric Supply Works—Machinery Hall .. 104
Leading Articles:—China and Japan—Testing a Bridge to Destruction .. 105
Brighton Beach—Albion Colliery Explosion .. 106
The Coal Trade .. 107

## TO CORRESPONDENTS.

**Registered Telegraphic Address, "ENGINEER NEWSPAPER, LONDON."**

*** *In order to avoid trouble and confusion, we find it necessary to inform correspondents that letters of inquiry addressed to the public, and intended for insertion in this column, must in all cases be accompanied by a large envelope legibly directed by the writer to himself, and bearing a penny postage stamp, in order that answers received by us may be forwarded to their destination. No notice can be taken of communications which do not comply with these instructions.*

*** *We cannot undertake to return drawings or manuscripts; we must therefore request correspondents to keep copies.*

*** *All letters intended for insertion in* The Engineer, *or containing questions, should be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever can be taken of anonymous communications.*

J. W.—*Your letter is an advertisement, and as such we cannot insert it.*

G. F. B. (Westgate Bridge).—*The address of the Brownley Injector Company is 150, Broadway, New York.*

### THE HEINE BOILER.

*(To the Editor of The Engineer.)*

Sir,—We should esteem it a favour if you or any reader could tell us the name of the makers of the Heine boiler. Any information respecting same would help us. T. L.

Manchester, July 26th.

### NEW GAS FOR GAS ENGINES.

*(To the Editor of The Engineer.)*

Sir,—We are asked for a new gas engine which works with gas produced by means of acid and certain decomposable materials instead of with the ordinary or with Dowson gas. Can any reader give us the name of the maker of the engine or of the gas apparatus? F. B.

London, July 31st.

### RURAL WATER SUPPLIES.

*(To the Editor of The Engineer.)*

Sir,—I venture from my very long experience in the obtaining water and in its distribution, to inform your correspondent "Sanitary Inspector" that there is little or no difficulty in pumping water from a well 500ft. away from the well; the lift the pump alone has to do is that it is limited to 30ft., and this only under favourable circumstances. There is a little to be considered with regard to the suction pipe, not only that it should be somewhat larger than a more direct or shorter one, on account of the friction set up by the water rubbing against the surface of the pipe, but by the stopping and again starting a long and perhaps heavy column of water, and to obviate this difficulty I introduce a small air vessel as near the pump as possible, and any ordinary lift pump under the circumstances should overcome the supposed difficulty. With regard to the hardness of the water the schoolmaster must certainly have gone abroad, otherwise Clarke's process must surely have got some note by this time, as it is very nearly forty years since it was applied and used at the Plumstead Waterworks, and has been used at Canterbury, and I have applied it in many breweries and private supplies. Most will know that it is simply what is known as quick-lime dissolved in any water and put into the hard water at the rate of about half-a-pint of the saturated lime-water to twenty gallons of the hard water, and it is found that water of what is known as 20 deg. of hardness is reduced to 5 deg., so that by investing about a shilling in lime and its application, will save something approaching £20-worth of soap. Richard Allison.

Ipswich, July 31st.

### SUBSCRIPTIONS.

The Engineer *can be had, by order, from any newsagent in town or country at the various railway stations; or it can, if preferred, be supplied direct from the office on the following terms (paid in advance):—*

| | |
|---|---|
| *Half-yearly (including double number)* | £0 14s. 6d. |
| *Yearly (including two double numbers)* | £1 9s. 0d. |

*If credit occur, an extra charge of two shillings and sixpence per annum will be made.* The Engineer *is registered for transmission abroad.*

*A complete set of* The Engineer *can be had on application.*

*In consequence of the reduction of postage on newspapers to one uniform rate for any destination outside the United Kingdom, Foreign Subscriptions will, until further notice, be received at the rates given below. Foreign Subscribers paying in advance at these rates will receive* The Engineer *weekly and post free. Subscriptions sent by Post-office Order must be accompanied by letter of advice to the Publisher.*

| | |
|---|---|
| Thin Paper Copies— | |
| *Half-yearly* | £0 18s. 0d. |
| *Yearly* | £1 16s. 0d. |
| Thick Paper Copies— | |
| *Half-yearly* | £1 0s. 8d. |
| *Yearly* | £2 0s. 6d. |

Reading Cases.—*The Publisher has in stock reading cases which will hold thirteen copies of* The Engineer. *Price 2s. 6d. each.*

### ADVERTISEMENTS.

*** *The charge for advertisements of four lines and under is three shillings, for every two lines afterwards one shilling and sixpence; odd lines are charged one shilling. The line averages seven words. When an advertisement measures an inch or more, the charge is ten shillings per inch. All single advertisements from the country must be accompanied by a Post-office Order in payment. Alternate Advertisements will be inserted with all practical regularity, but regularity cannot be guaranteed in any such case. All except weekly advertisements are taken subject to this condition.*

*Prices for Displayed Advertisements in "ordinary" and "special" positions will be sent on application.*

**Advertisements cannot be inserted unless delivered before Six o'clock on Thursday evening; and in consequence of the necessity for going to press early with a portion of the edition, ALTERATIONS to standing advertisements should arrive not later than Three o'clock on Wednesday afternoon in each week.**

*Letters relating to Advertisements and the Publishing Department of the paper are to be addressed to the Publisher, Mr. Sydney White; all other letters to be addressed to the Editor of* The Engineer.

### MEETINGS NEXT WEEK.

British Association for the Advancement of Science.—Wednesday, August 8th. Address of the President, Lord Salisbury, at 8 p.m. Meetings of the sections on following days.

# THE ENGINEER.

*AUGUST* 3, 1894.

## CHINA AND JAPAN.

The war, which has evidently now commenced in earnest, and which is likely to become worse before it is ended, has aspects specially interesting to engineers. If judged by area, population, and wealth, China is as a giant to a dwarf when compared with Japan, but much of this superiority is latent only, and it is questionable if it can be brought effectively to bear. Probably most of those who are familiar with both countries would agree that the Chinese are, as a race, the more astute, that their intellectual capacity is greater, and that, given the same opportunities and training, they would excel the Japanese in most walks of life. But this potential capacity is neutralised and restrained by the absurdly antiquated systems and principles under which the country is governed. The breaking down of these barriers to progress is a condition precedent to the reforms which will open out the country to Western civilisation and to the arts of peace and war necessary to her greatness. It is not at all unlikely that the present war may be the beginning of a social and political revolution which will tend to the advantage not only of China herself, but to all in Great Britain who are interested in engineering enterprise, as well as to the manufactures allied with and arising out of such enterprise. At first sight the difference between the two countries—except in size and wealth—is not apparent, so far as we are concerned. Both have come to Europe for warships, armaments, telegraphs, and railways, but in a very different spirit. Japan has, to the full extent of her powers, adopted modern methods where they are likely to be beneficial, and has sent her young men to England, France, Germany, and America to learn how to make and manage the wonderful tools of the Western World. This policy has already borne fruit. In the technical colleges, arsenals, factories, and hospitals which Japan has established she is every year becoming less dependent on European assistance, and more able to hold her own in any contest where the maintenance and replenishment of armies, ships, machinery, and weapons are important. The Chinese, on the contrary, have only come to us when military necessity has forced her to obtain assistance from Europe, but she detests the "foreign devils," teaches her people to despise them as mere clever craftsmen of inferior race, and gets rid of them as soon as she can. The officers, engineers, foremen, and workmen who have gone from here are grudgingly received, and are utilised without any thanks or due appreciation of their skill. Electric telegraphs were opposed for all kinds of childish superstitions engendered by the governing class, and were finally adopted only as an aid to the central government in communicating with the provinces. Commercial advantage and the general good of the country were reasons which carried no weight whatever. The few railways which have been made in the North of China were permitted almost solely as a protection to Pekin, and to keep open the communication between the capital and the sea. The development of mines and trade, which has to a small extent followed, seems to produce no desire for extensions, and such desire will never arise or have effect till the spirit which underlies the government of the country is exorcised. In the island of Formosa the enlightened Viceroy, who established a railway and who attempted to open out the collieries, has been snubbed and superseded; the proposed coaling station is abandoned, and progress of all kinds arrested. It may be said that the Chinese have, at any rate, war steamers and big guns. But they are worse than the Turks in their management of them. He would be a brave man who ventured on a steamer whose boilers were under the control of Chinese engineers, and the same criticism may be applied to all branches of the public service. There is an army large enough, if judged by numbers, but, except in regard to the *corps d'élite*, most of the soldiers are still armed with bows and arrows and antiquated matchlocks, while their strategy is, to a considerable extent, dependent on omens for guidance. Ill-armed troops, which can only march four or five miles a day for want of good roads, will find their numbers of small avail when in conflict with a country like Japan, which, small as it is, can concentrate her well-armed and disciplined forces rapidly by modern methods.

China may court victory and propitiate her gods by letting off fireworks, as her doctors try to cure diseases by incantation and the burning of coloured paper, but such methods are clumsy and ineffectual. The hope for China lies in the fact that the better part of the people are not wholly adverse to European methods. The few railways which are opened are eagerly used, and if popular animosities against the foreigner were not stimulated by the governing classes who, for their own ends, encourage the superstitions of the people, reforms would be accepted. But, just as in Japan a generation ago, the ancient and now anachronous power of the nobles had to be modified, and freedom to use Western methods arose only when the Daimios, with their two-handed swords, had their power taken away, so in China the mandarins, who deem the doctrines and rules of Confucius all-sufficient, will have to be restrained before the country can be opened out, and the present war may be the beginning of it. If the Japanese can gain immediate advantage before the Chinese can crush them by mere force of numbers, defeat and military necessity—which are the only arguments appealing to the Chinese mind—may lead her to modify her present system of seclusion, and induce her to utilise the aids to peaceful progress and to real national strength, which we are willing and anxious to give her.

Korea is a mere incident of the struggle; but if Japan prevails, the opening out of the peninsula will be of great advantage to manufacturing countries like our own. A revival of trade in England is looked for; the burden of the capitalist who seeks investments for his money is becoming hard to bear, and it will be interesting if the present cloud in the East is to open out into profitable opportunities so urgently wanted, but which seem to be denied us elsewhere. It is worth noting, however, that while in Eastern and other semi-civilised countries, many obstacles and delays are encountered in the attempt to introduce British manufactures, especially those in which engineers are interested, there is, on the other hand, a freedom from restrictions of another kind which hinder progress here. Vested interests are hard to deal with in Great Britain, especially those which control the occupation or use of land and public roads. Even in England there are vast openings for the industrial investment of capital, if we could but remove some of our ancient restrictions as to traction on common roads, and as to improvement in the means of conveying passengers in busy towns.

## TESTING A BRIDGE TO DESTRUCTION.

It is known that on a few occasions the operation of testing a bridge has, probably more by accident than design, been pushed to an extreme neither judicious nor justifiable. In certain cases of testing, such as those relating to specimens and samples, which are prepared and intended for the express purpose of ascertaining their ultimate resistance to stresses of various descriptions, it is necessary to carry the experiments to the point of rupture. But in the instance alluded to, and perhaps in others, the limit of the elasticity of the material should be the standard by which to regulate the severity of the test. A stress of an excessive character injures this all-important quality, and permanently damages the object experimented upon. The testing of materials has in recent times been carried to a pitch formerly never contemplated. Most technical schools and colleges are provided with costly machines, which afford to the student and young engineer ocular proof of what in the majority of instances is a foregone conclusion. It is scarcely necessary to refer to the class of tests undertaken by skilful and competent men who possess works and machines of their own. and conduct the process as a matter of business, and by their ability and integrity, have contributed much valuable and reliable information respecting the strength of materials. Apart from official tests relating to engineering and architectural structures of a public nature, the Governmental departments, and almost every private manufacturing firm, are continually engaged in conducting trials and experiments which, while no doubt possessing special interest, have also a general value in all that pertains to the ever-advancing progress of the arts and sciences.

Another and very important class of tests comprises those undertaken by the engineers in charge of extensive professional works. While the results arrived at are added to the existing fund of combined theoretical and empirical knowledge on such subjects, the tests themselves, similarly to those quoted above, are devised for a special purpose, and conducted with a special object in view. They have a particular and specific relation to those peculiarities of design and construction which constitute the distinguishing characteristics of the work in hand. It is frequently not general information respecting the strength of any given material that is required, so much as the strength and powers of the resistance it will display under the conditions to which it will be subjected. To start *ab origine* and in corroboration of our last remark the experiments in connection with the building, breaking, repairing, and in the numerous repetitions of these latter two operations in the case of the "model tube" of the Britannia Bridge may be cited. That a very large amount of perfectly new and greatly needed information respecting the behaviour of wrought iron under stress was derived from these tests no one will deny. At the same time the great object of them, the chief object at least was to ascertain the direct proportions to be given to the bridge itself, and the manner in which the material could be distributed to the best advantage. Whether these results were as fully achieved as they might have been is now beside the question. At any rate, the Britannia Bridge still spans the Straits of Menai, notwithstanding the increase in the load it has to carry since it was erected, a cause which has led to the demolition of some of its younger brethren, and their replacement by new bridges. Although not exactly a plate girder bridge, it belongs to the continuous web type, a fact to be noticed for a reason that will shortly appear.

Among the defects—or, perhaps more correctly speaking, the deficiencies—of all mere technical tests as distinguished from genuine professional or working ones, the principal is that they are conducted on a more or less limited and imperfect scale. Indeed, the usual method of procedure more frequently than otherwise does not admit of a very liberal treatment or development of the process. A concentrated load or its lever equivalent is all that can be obtained from the expensive machines already mentioned; and the fallacy of arguing, from the effects thus produced, what will be the attendant conditions with a different disposition of the loading, has before now led to very unpleasant results. So far as the mere size of the specimen is concerned, it is well known that in several instances reasonably large specimens have been subjected to tests of a destructive character—such as cast and wrought iron girders, columns and pillars, and built-up struts and other sections of iron. But even in the ordinary working specifications for testing, the specimens of the material to be operated upon rarely exceed the somewhat insignificant length of 8in. As a test that the quality of the material as specified is secured, these proofs are indispensable and satisfactory; but whether the specimens be large or small, whole girders, columns, or component parts of bridges, the conditions attending the loads and stresses, not necessarily pushed to destruction, do not always represent those to which the material is exposed when under its actual working strain, great or small. It may be argued that for this discrepancy between what may be termed in some sense theoretical and practical testing, there is no remedy. All that can be done, which is not very much, is to assimilate the conditions as much as possible. We cannot repeat the "model tube" experiments. It would be impracticable, and also wholly unnecessary, to construct a model of the Forth or Brooklyn Bridges upon any scale that would afford reliable results, and then proceed to break it. Before either of these stupendous structures were erected, the capabilities of steel—the material used in the construction of both—were ascertained, and its employment with safety guaranteed beyond all doubt. It is clear, therefore, that there was nothing to be gained, even had it been practicable, by experimenting upon a model bridge; and as it was, the factors of safety were, we believe, with respect to the Forth Bridge, settled between the Board of Trade and the engineers for the bridge.

While admitting the difficulty, and consequently the rarity of testing to destruction a working example of a bridge, it will be conceded that when an opportunity does present itself of carrying out so valuable and unusual an experiment, it should not be neglected. Such an instance occurred recently in the case of the Wohlhusen railway bridge, which is deserving of investigation, and something more than mere casual attention. Built twenty years ago to carry the line from Berne to Lucerne on the Jura-Simplon route over the river Emme, this bridge gave last year unmistakeable signs of being no longer fit for the increased weight of the traffic, and was replaced by a new structure similarly of iron. Before demolishing the old bridge, the Swiss railway authorities decided to remove it bodily, and place it—main, cross girders, and platform, all complete—upon small abutments built for the purpose, about a couple of feet above the level of the adjoining river bank. In the columns of The Engineer we drew attention to the collapse of the bridge at Mönchestein, near Bâle, between which and that at Wohlhusen there is a general resemblance with respect to span, depth, and the disposition of the lattice web. web. The bridge thus selected for testing to destruction was on the skew at an angle of 48 deg., which caused one panel or bay of the one main girder to overlap the succeeding one in the other girder, thus obviously rendering impossible a uniform distribution of a moving load. It was situated on a curve of the line of fifteen chains radius which had a single track, with a gradient of 1 in 55, and was 140ft. in span, 19ft. in depth, a ratio of about 1 to 8, and with a length of panel equal to 14ft. The main girders are of the old Warren type, with its single triangulation of isosceles triangles in the web. Both the diagonal ties and struts are of a similar section, and built up of double tee-irons braced together and stiffened by intermediate angle-irons and plates. A trough shape was given to the booms of the main girders, which were 17ft. apart, and connected together by the counterbracing usual in the case of deep through bridges. Cross-girders and rail-bearers supported the iron platform. We do not intend to enter into all the details of the breaking test, but to describe merely such portions of them as will enable our readers to understand the grounds upon which we found our opinion respecting the ultimate failure of the bridge.

Ordinary rails and ballast, piled up in successive layers, were used for the experimental loading, which was gradually spread over the half span of the bridge, until its total amount was equal to, per foot run, nearly four times that of a heavy goods train and locomotive. During the whole trial, the greatest care was observed to note and measure accurately all differences of level, deflections of the booms, flexure of the bars of the web, on any departure or deviation to the smallest extent of any member of the truss, from the normal plane which defined the limits to which such alterations in form might safely extend. When the test or live load, to which must be added the dead weight of the superstructure itself, amounting to 78 tons, covered the half span, it was further augmented to nearly 4½ tons per foot run, a sudden cracking sound was heard, and almost immediately afterwards the whole structure gave way. Experience has confirmed this almost instantaneous collapse in other instances of the downfall of railway bridges.

During the progress of the testing, the observations showed that the effects of the load were gradually and increasingly apparent in the different members of the main girders, but not to the same extent. Comparatively the booms suffered but little deformation, and as in similar instances where the failure was not the result of design, but brought about by defects in the structure itself, the web constituted the weak part, and the bars in compression, which were inclined nearly at angles of 45 deg., the chief defaulting members. The main girders deflected at their centre to an amount measured by inches, while the vertical bars became bent likewise, and thus the booms were brought closer together in consequence of the diminished depth of the girder, and the general deformation and inevitable distortion of the whole framework ensued. Small cracks likewise made their appearance in different parts of the ironwork. A curious instance of cracks occurring in cast iron was afforded by the columns supporting an iron viaduct on one of the Moravian railways. They took the form of thin longitudinal fissures, and eventually the authorities replaced them with pillars of wrought iron. The original columns were filled with concrete, and it is possible that the unequal expansion and contraction of the two materials in a climate far more rigorous than our own, may have given rise to the splitting.

If we connect the destructive testing of the Wohlhusen Bridge with that of other bridges all of the same open web type of construction which have collapsed of their own accord, the very pertinent question presents itself whether the plate or continuous web girder is not after all better adapted to resist tests of a destructive character than when the connection between booms and web is discontinuous. This question demands some consideration, not only with regard to actual facts and existing examples of bridges, but because, as we have already pointed out in our columns, engineers both at home and abroad are showing a decided preference for very open web girders, or those in which the panels or bays are very long, the diagonals in corresponding proportions, and consequently the points of connection between the booms and the web at much greater intervals. Under these circumstances the whole boom becomes a continuous girder, although not exactly resting upon immovable intermediate supports. The economy—especially so far as the diagonal struts are concerned—of this system of construction, we have previously admitted in former articles, and see no reason for altering the opinion already expressed, but we are now regarding the subject from a different standpoint, which, whether true or false, will not affect the validity of what has been advanced on the score of economy.

In the disposition of the test load, it is obvious that it was the intention of the experimentalists to assimilate the conditions of the trial as closely as possible to those which would actually obtain in ordinary traffic. Thus the load was successively advanced from one of the abutments, panel by panel, until it had been spread over just one half of the span, and the important point to be noticed here is that the downfall of the bridge occurred when the position of the rolling or live load was such as to produce the maximum shearing stress on the web at the centre of the girders. This is exactly contrary to what occurs with regard to the stresses on the booms, which reach a maximum when the rolling load covers the whole span, which is practically equivalent to a uniform distribution of it. Neglecting the dead load or weight of the structure itself, since its shearing effect is equal to zero at the centre of the span, we shall have, if our figures are correct, the diagonal component of the shearing stress, or the actual stress upon the centre struts of the web equal to thirty tons. While it is quite possible that their net sectional area might have been sufficient to withstand a greater stress, it is evident that they did not possess the requisite degree of resistance to flexure, as they visibly doubled up towards the end of the experiment. It should be remarked that when the bridge failed the amount of the test load and the dead weight upon each girder was a little under 2½ tons per foot run, which might leave a sufficient margin over and above the working stress due to the maximum traffic loads of a single line of railway in Switzerland some twenty years ago.

We have termed the test load a live one, but it scarcely deserves the name, and should strictly be regarded in the light of a load not uniformly distributed. This assumption will not theoretically alter the calculations respecting the stresses, although there is not the slightest doubt that, practically, had the test load been endowed with the *vis viva* of an express train the structure would have collapsed long before it attained to the breaking proportions.

## BRIGHTON BEACH.

More than four years have passed since we last adverted in these columns to the above subject. When we did so we described the several precautions either then taken or in contemplation to stay the constantly increasing denudation of shingle upon the sea frontage. It may be as well, perhaps, before reviewing the results we see have followed those precautions, to recall to the minds of our readers the circumstances under which the denudation remarked upon had arisen. Following the execution of new harbour works at Shoreham, about 4½ miles to the westward, a large accumulation of beach had taken place at Aldrington, a parish contiguous to that suburb of Brighton known as Hove. This accumulation formed a projecting headland that diverted from its original course the drift of the shingle to the eastward. Hove beach thereupon soon became bare of this natural defence, and all the efforts made by Mr. Ellice Clarke, M. Inst. C.E., then engineer to the borough, failed to restore this. After several years of anxious but futile experimenting with groynes of various designs, it was deemed necessary to seek the advice of the late Sir John Coode, M. Inst. C.E. This expert decided upon the erection of a permanent sea-wall, with short groynes at its base. The construction of this gave the protection needed. But the result was the attack by the sea on the beach of the adjacent town of Brighton, and now the anxieties previously felt at Hove have been transferred to the former place.

When last we touched upon this topic, now—as we have said — more than four years ago, we stated that it was the intention of the Brighton authorities to construct a series of very long groynes in the vicinity of the West Pier. A recent visit to the town has enabled us to judge of the effect of these. While they were in contemplation only we expressed great doubt as to whether even the great length to be given them would reach the altered line of the travel of the shingle eastward. In some degree, this doubt has not been justified by results. There has been, most certainly, a degree of addition to the beach on the section dealt with by these new groynes; but it is noticeably of very light stuff. The proportion of what may be termed solid shingle is relatively small, and the absence of this must render it doubtful if, under the attack of exceptionally heavy seas from the south-west, it would remain undisturbed. We are, however, willing to give the design the benefit of this doubt, and to admit that some amount of protection has been gained; but most certainly this has only been attained by a serious sacrifice of the appearance of the beach, as well as of the pleasure uses to which it is put by the visitors to the town. It may almost be said, indeed, that at this—the principal point of resort of these pleasure seekers—there is now more of groyne than of beach. Several of the new erections are massive structures of concrete; and these, although more permanent and reliable, are undeniably not picturesque objects, such as wooden groynes after a certain time undoubtedly do become. The immediate object has, however, in a degree been gained; and probably this is all that the Town Council much cares about. But it must await the experience of many years before it will be possible to decide whether even the limited advantages at present secured may be regarded as likely to be of a permanent character.

As in all former cases of the localised treatment of the beach, the driven-back sea is taking its revenge to the eastward. Between the west station of the Volks' electric railway and the old Chain Pier, the inroad by the sea has become so great as seriously to threaten the structure of the line. This has ever been a "tender spot" in the town's maritime defence, and we fear, since the erection of the groynes before referred to, it has become far more difficult effectually to deal with. But it is when we proceed still further eastward that the effects of the western works are most to be seen. From the Chain Pier, and for the whole length of beach facing the Madeira-walk, the loss of shingle since the time we offered our last remark upon this subject has evidently been seriously great. The waves now attack the carriage road of the undercliff, and it must be merely a question of time as to the necessity for undertaking extensive work to protect this. At many points there now remain but a few yards of light sandy stuff where before the solid shingle extended for a great length seawards. The Corporation has expended, and is still expending, very large sums in making this favourite walk and drive ornamental and attractive, and it cannot afford to remain inactive and see all the work done destroyed by the encroaching sea. So averse have the local authorities shown themselves to follow the example set them by those of Hove, that we despair of their admission of the principle adopted by the latter, that the first expenditure upon a sea wall, although large, must prove in the long run to be the cheaper of the two systems. Hove having adopted it, now rests and is thankful. Brighton must for many years remain in an opposite condition to this. The time may be reached when immunity may be secured, but it can only be at the cost of increased destruction to the cliffs between the town and Rottingdean, the progress already experienced in that direction having some little time back enforced the removal of fully a mile of the coast road further inland. This same progress has, as is well known, before this seriously threatened the main drainage of the town.

This last consideration must operate for many years to come, even when, at the cost of utterly disfiguring their beach, the Corporation has recovered the ground lost by it. We are perfectly aware that this body has a strong reason to urge against a sea wall of the kind adopted at Hove. It argues that such a wall would destroy the beach for use by bathing machines and pleasure boats, and so remove one of the chief attractions of the town to visitors. We admit that this consideration is not without force; but it yet seems to us that some method might be designed to avoid the sacrifice dreaded. As matters have gone so far as they have, however, it is probably too late to retrace the steps taken at so large an expenditure. We can only now regard the past and future battle with the sea at Brighton as being one most instructive to all of our profession concerning themselves with maritime defences.

## ALBION COLLIERY EXPLOSION.

The coroner's jury on the deaths arising from the Albion Colliery explosion, after an inquiry lasting over nine days, have given their verdict, which is much more to the point than verdicts are generally on colliery explosions. As a rule, juries find that there is not sufficient evidence to show how the gas was ignited. Thus, after the explosion at the Abercarne Colliery, also in the South Wales district, in 1878, when 268 men perished, the verdict was to the effect that there was no evidence to show how the accident occurred. The inquiry into the explosion at Seaham Colliery in Durham, in 1880, when 164 men were killed, the jury found that an explosion had occurred, "but as to the seat of the explosion we have not been able to determine." Yet, for the purpose of determining the cause of this explosion, Sir Frederick Abel had, under instructions from the Home Secretary, made a number of experiments on samples of coal dust collected at the Seaham Colliery, and an exhaustive report, which proved that the existence of very small quantities of inflammable gas in the air of a mine may suffice to bring about a propagation of flame with the addition of coal dust, and by that means cause an explosion. Since then the further experiments made by Mr. Henry Hall, H.M. Government Inspector of Mines, for the Royal Commission on explosions from coal dust in mines, demonstrates the danger of using gunpowder in fiery pits. The jury, in their verdict on the Albion Colliery, state that they are "unanimously of opinion that shot-firing was practised in the colliery, when the men were at work, without sufficient precautions as to their safety, and contrary to rules;" and they further state "that there is not a proper system of watering the mine." This very clearly shows that the jury attributed the explosion primarily to shot-firing in presence of coal dust. Among the recommendations made by the jury is one which certainly might well be added to the general rules of the Coal Mines Regulation Act, namely, "That a record shall be kept of the number of men in the mines at all hours." Considering the uncertainty of life in the best-managed coal mines, it appears strange that no regulation exists for registering the names of persons underground at all times. The jury also recommend more frequent inspection by H.M. Inspectors of Mines, as they consider that "the present examinations by the workmen's representatives are worthless." This opinion is not in harmony with that expressed by the Royal Commission of 1886, for at the end of the report the Commissioners state that they "attach much importance to systematic inspection by workmen, under Rule 30 of the Coal Mines Act of 1872." The careful study which has been made in late years of colliery explosions points clearly to the great danger of blasting in fiery mines, even when a small quantity of inflammable gas exists in presence of dry coal dust. The rules laid down in the Coal Mines Regulation Act are apparently not sufficient to ensure safety. There is but one possible conclusion, namely, that blasting must be altogether prohibited or rigorously restricted to the use of the so-called "high" explosives which detonate without giving off a dangerous flame. Mr. Hall's conclusions respecting dust explosions and the dust of the Albion Colliery, as embodied in his report dated August 20th, 1893, were referred to on page 11 of our impression of the 6th ult.

### THE COAL TRADE.

Both parties to the truce in the coalfield are loyally endeavouring to carry out its conditions. The joint secretaries of the Conciliation Board met in Manchester on Tuesday, when the lists of collieries in the various districts consenting to accept the arrangement were handed over. The names of these collieries have not been published, but they are understood to include the larger and more important undertakings in the whole of the districts covered by the Federation, and there are very few, if any, exceptions in the case of the collieries associated with the Coalowners' Federation. Another gratifying feature is that there are many non-associated collieries assenting. It is stated that there are other collieries, not included in the Federation, the proprietors of which are anxious to join in the agreement. As it is desirable that the new conditions shall cover as large a portion of the coalfield as possible, a circular has been issued which will enable those non-associated collieries to come within the settlement made at the meeting of the Conciliation Board on July 19th last. The proprietors of these collieries have been informed that they may be included in a supplementary list, provided they communicate their desire to Mr. T. Ratcliffe Ellis, solicitor, Wigan, on or before Monday next, August 6th. On both sides further efforts are being made to maintain selling prices. The Erewash Valley Colliery Owners' Association met last Monday. Having regard to the fact that the present quotations are now at their lowest summer level, the Association passed the following resolution :—"That this meeting unanimously resolves that the present selling prices be maintained." If this decision can be carried out, and the example thus set followed in the Midland coalfields generally, the result would undoubtedly be to steady the coal industry, and contribute to satisfactory and peaceful working for two years at least. The entire effect would be wholesome, as giving confidence in commercial circles, and affording absolute assurance that there will be no further rupture for a definite and, considering the frequent disturbances of late years, an unusually prolonged time.

## LITERATURE.

*A Handbook of Gold Milling.* By Henry Louis, F.G.S., &c. 8vo., 540 pp. London: Macmillan and Co. 1894.

Under the modern conditions of gold production, owing to the rapid exhaustion of alluvial and other easily wrought deposits, the world is becoming dependent for the maintenance of its supply of the precious metal upon mines whose ores contain an almost infinitesimal proportion of useful to waste material. Such ores—containing from four to five up to at most forty or fifty parts of gold per million of rock—must necessarily be treated upon a very large scale in order to obtain any useful return on the outlay necessary for the establishment of even a moderate sized reduction plant. It is not surprising, therefore, that the office of millman, amalgamator, or reduction officer, as the person in charge of the gold-saving works is differently styled in different parts of the world, has developed from a mere dependency of the underground works into perhaps the most responsible position on the staff of the mine. For the use of those who may be called upon to undertake such duties, Mr. Louis has in this volume brought together a large amount of valuable material, representing the accumulated experience of quartz-mill operators in all parts of the world, but principally in the Western States of North America, which have been foremost in the development of this branch of mining work. In the earlier chapters, full and complete accounts are given of the physical and chemical properties of gold, and also of those of mercury; the methods for obtaining and keeping the latter metal in a sufficiently pure state for amalgamating purposes, and the precautions necessary for checking and preventing waste in amalgamating, being treated with considerable detail. The author is inclined to believe that the property known as "rustiness" in gold, which prevents the free action of mercury upon the metal, may be due not so much to actual films of rust on the surface as to the existence of an allotropic condition of gold only soluble in mercury with considerable difficulty, as compared with the ordinary crystalline variety, which amalgamates very readily. The same slow solubility characterises the amorphous brown gold obtained by precipitation from weak solutions by ferrous sulphate or other reducing agents; and therefore the author thinks that the presence of such an amorphous metal in the ore may sometimes be the cause of loss in working rather than rust in the literal sense. Since the publication of the volume, this subject has been more fully considered by him in a paper read before the American Institution of Mining Engineers at their meeting in Montreal in February last.

The construction of the stamp mill and its accessories forms the subject of several chapters, every part being considered in detail, with the assistance of numerous carefully drawn illustrations. Much attention has been paid to demonstrating the mechanical principles involved in the design of each part, and, as a whole, this section gives a very complete idea of the points to be attended to in building stamp mills. The author, however, seems to have a very poor opinion of British pig iron, for in discussing the construction of stamp heads, which "should be of first-class quality, low in phosphorus and silicon, of close even texture throughout," he states that "No English iron should be used in the mixture."

Other crushing machines, such as the arrastra and Huntingdon mill are described, but in less detail, as foreign to the main purpose of the work, which is devoted to the construction and working of stamp mills, and for the same reason, concentrating and amalgamating plant are only described to the extent necessary for explaining their uses as accessory to bettering amalgamation. The use of chlorine and the Macarthur-Forrest process, the latter under the somewhat uncouth term of "Cyanidation," in the treatment of mill tailings and concentrates are briefly noticed, and the final chapter is devoted to a description of the methods of assaying gold ores and bullion as required in the current practice of an amalgamating mill.

Within the limits to which the author has chosen to confine himself, the work is exceedingly well done, and it cannot fail to be of value to those engaged in gold-mining work, whether as beginners or as more experienced hands, whose tenderfoot period has long been passed; and a word of commendation is certainly due to the publishers for the excellent manner in which the work is turned out.

## THE BRITISH ASSOCIATION.

The 1894 meeting of the British Association begins next Wednesday night, at Oxford, with the delivery of the address of the incoming president, Lord Salisbury, Chancellor of the University of Oxford. Lord Rosebery will be at the Association as one of the vice-presidents. The opening meeting will be held in the Sheldonian Theatre, which will only accommodate 1800 persons, so that it is possible that some among the late comers may be unable to obtain entrance. The programme of the papers to be read before Section A is still far from complete, many authors having not yet sent in either their papers or abstracts thereof. This section is usually overcrowded with papers. Especially has it been so of late years, when so large a proportion has been on the subject of electricity. A sub-section to deal with that subject seems to be necessary to give relief from its undue preponderance, and for the benefit of those members who care more for the numerous other subjects with which Section A has to deal. Professor A. W. Rücker, of South Kensington, is the president of this section. A course of lectures which he gave some years ago at the Royal Institution was recognised by those present as of exceptional ability, presenting clearly in popular form some of the most abstruse recent problems and discoveries in relation to molecular physics. Among those who usually take an active part in the proceedings of this section, and who are expected to do so at the coming British Association meeting, are Lord Rayleigh and Lord Kelvin.

Section B, Chemistry, has had its title extended to that of "Chemistry and Mineralogy," the latter science having previously been somewhat neglected at the British Association; it is also one which, like forestry, is more largely studied and taught abroad than at home. The president is Professor H. B. Dixon, who is said to intend to advocate improvements in the system of teaching chemistry at Oxford University.

The programme of the proceedings in Section G, Mechanical Science, is in a creditably forward state, and some one or two of the papers will be discussed jointly with Section A. The president of Section G is Professor A. B. W. Kennedy. About the proceedings of this section during the coming British Association meeting there is at present nothing fresh to add to a recent summary given in the *Times*, which said that Professor Kennedy will take as the subject of his presidential address, "Modern Mechanical Training, Constructive and Critical." So full is the programme that, for the first time for many years, the section will meet on Saturday, for which a paper of special interest by Sir A. Noble, on the measurement of pressure in gun-bores, will be the chief item. In this section the various days of meeting have already had their subjects allotted. On the Thursday after the President's address, Sir Frederick Bramwell will give a paper on some reminiscences of "Steam Navigation on Common Roads," which is expected to be followed by a discussion. This will be followed by a paper by Professor Fidler on the "Plastic Properties of Iron and Steel." On Friday will take place the joint discussion with Section A, first, on "Integrators," which will be opened by Professor Henrici; and, second, on "Flight," which will probably be preceded by a paper by Lord Kelvin on "Resistances Experienced by Solids Moving Through Fluids." The remainder of the day will be devoted to civil engineering papers. There will be one on "Tunnel Constructing by Shields," which has come so much to the front lately, by Mr. Fitz-Maurice; and another on "Bore Hole Wells for Town Water Supply," by Mr. H. Davey. On Saturday, besides Sir A. Noble's paper, there will be another by Mr. B. Donkin on "Steam Cylinder Temperatures," with a valuable set of experiments, while Mr. J. Kenwood will give a paper on "Modern Lighthouse Work." Monday will be devoted to electrical subjects. Mr. T. Parker will describe the Oxford electric light system. Mr. W. H. Preece will give papers on his own experiments on "Signalling without Wires," and on "Efficiency of Glow Lamps," on which he has been doing much work. Tuesday will be devoted to mechanical engineering, when Professor Unwin will give a summary of the report of the Steam Dryness Committee. Other papers will be by Professor D. S. Capper on "Calibration of Laboratory Instruments;" by Professor Beare on "Steam Losses;" and by Mr. H. F. Burstall on the "Temperature Entropy Diagram."

Sections A and B will meet in separate theatres in the Museum; Section G will meet in Keble College Hall. Of the two usual conversaziones the first will be held on Thursday, August 9th, at 8.30 p.m., at the University Museum, and the second on Tuesday, August 14th, at 8.30 p.m., at the new Examination Schools. On Friday, August 10th, at 8 30 p.m., Dr. J. W. Gregory, of the British Museum of Natural History, will lecture at the Sheldonian Theatre upon "Experiences and Prospects of African Exploration," in place of Mr. W. H. White, Chief Director of Naval Construction, on "Steam Navigation at High Speeds." Mr. White has been ordered to go abroad, so cannot deliver his lecture. On Monday, August 13th, at 8.30 p.m., Professor J. Shield Nicholson will lecture in the Sheldonian Theatre on "Historical Progress and Ideal Socialism." On Sunday, at 8.45 p.m., there will be a concert in Balliol College Hall: applications for tickets must be sent early on Friday to the Entertainment office. During the time the British Association is at Oxford a number of general and private garden parties will be given. Professor J. W. Sollas, of Trinity College, Dublin, will lecture to working men at the Clarendon Press Institute, Walton-street, Oxford, on Saturday, August 11th, at 8.0 p.m., on "Geologies and Deluges." Admission free to members of the Institute, and to working men resident in Oxford.

The British Association excursions on Saturday, August 11th, will be (A) to Blenheim and Woodstock; (B) to Nuneham, Dorchester, and Wallingford; (C) to Nuneham and Abingdon by river; (D) a geological excursion to Stonesfield; (E) to Silchester. The excursions on Thursday, August 16th, will be (A) to Windsor and Eton; (B) to Reading and Goring; (C) to Swindon Railway Works; (D) a geological excursion to Swindon; (E) Warwick and Stratford-on-Avon; (F) Edgehill, Compton Winyates, Broughton, and Wroxton.

More than one hundred foreign men of science will be present at the meeting, and upon some of them university honours will be conferred before they leave Oxford. The local secretaries at Oxford are Mr. Gilbert C. Bourne, M.A., Mr. G. C. Druce, M.A., and Dr. D. H. Nagel, M.A. We hereby express to them our respect, our condolences, and our sympathy. No man, it is said, who has occupied the position once of local secretary to the British Association has been known to accept the office again. Mr. George Griffith, M.A., of Harrow, is still back in his old post, so well occupied by him for years in the days of long ago, and it will appear unnatural hereafter to see anyone else doing the work. The reception room at the coming meeting will be the new Examination Schools, High-street, Oxford.

## PARLIAMENTARY NOTES.

*The flues of torpedo-catchers.*—A question was asked by Mr. Gourley on this subject, in answer to which Sir U. Kay-Shuttleworth said: The following information has been received from Commander Torlesse, late of the Havock and now of the Hornet, in relation to the question of my hon. friend. He says:—"I presume the Havock is meant. The Hornet has never used water for the purpose indicated, nor was she troubled with flame—from her funnels. No trouble has been experienced in the Hornet from flame—from the funnels—but in the Havock at full speed a good deal of flame has been produced at times. No special report has been made, as it was considered that more experience in stoking would reduce the flame. I have seen Commander Farquhar, of the Havock, who states that his object in having water thrown over the boat—on July 14—was to prevent cinders from the funnels from burning small holes in the canvas cover of the boat." Commander Torlesse adds:—"I had never regarded the boat as in danger of catching fire, but merely used the water as a precaution against damage." Further practice and experience will probably show whether it will be necessary to make a small alteration in the funnels of the Havock in order to prevent any undue smoke or flame. The best hand-picked Welsh coal is used. No smoke-consuming apparatus has hitherto been submitted to the Admiralty which is considered suitable for naval purposes.

*Technical workshops for soldiers.*—In every corps, and in all situations where it is practicable, the commanding officer is required by regulations to establish workshops for the employment and instruction of soldiers in various trades and handicrafts. Difficulties frequently arise through a deficiency of men of the various trades, and from other causes; and the large number of recruits in a battalion, in consequence of short service, necessarily militates against any large extension of the system, but where it can be carried out the result is considered generally satisfactory.

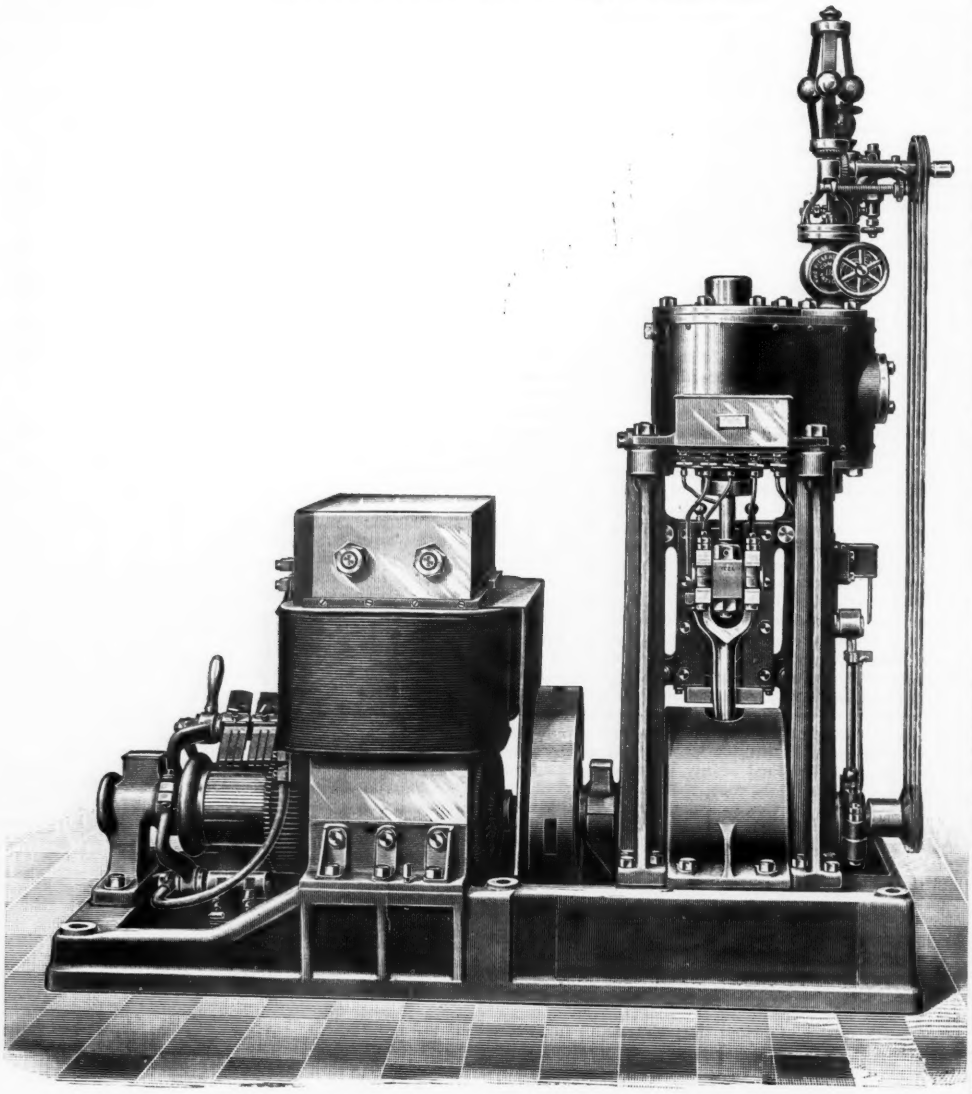
## PORTSMOUTH ELECTRIC SUPPLY WORKS.

In a recent number we referred to the inauguration of the Portsmouth Electric Supply Works, which have been carried out under Messrs. Kincaid, Waller, and Manville as consulting engineers, and Professor W. Garnett, by Messrs. S. Z. de Ferranti and Co., London, with engines constructed by Messrs. Yates and Thom, of Blackburn. On page 104 and 109 we commence the illustration of the machinery employed in these works. The engraving on page 104 is from a photograph taken in the engine and machinery hall; that on page 109 showing in some detail the construction of the engines. The dynamo, as will be seen from page 104, is of what is now known as the fly-wheel type. We shall give further illustrations and descriptions in another impression.

Death of Mr. G. O. Formby.—The death is announced at Liverpool of Mr. Geoffrey Oswald Formby, who in October, 1883, gallantly headed a party which descended the Severn Tunnel shaft to rescue fifty men suddenly imprisoned in the workings by the inrush of a tidal wave during a gale which affected nearly all parts of the country. Many of the readers of The Engineer will remember the event, and the generous account which is given of it in the book on the Severn Tunnel by the late Mr. T. A. Walker, who completed it. The water had extinguished the boiler fire of the winding engine on the bank and rendered the cage useless. Twenty-five men who at the time were engaged in a section below the shaft escaped by ascending the ladders affixed to the sides of the shaft, but the water continued to pour into the workings in such an enormous volume that their companions were unable to follow their example. As soon as the high tide began to recede a boat was lowered and launched in the tunnel by Mr. Formby, then a young engineer, and others. After considerable difficulty the workmen were rescued, only one life being lost, that being of a man who fell off the shaft ladder under the weight of descending water, which he unsuccessfully endeavoured to face. There is little doubt, the *Times* thinks, that Mr. Formby's plucky conduct on that occasion sowed the seeds of disease which, after prolonged suffering, terminated fatally at Liverpool on the 22nd ult., closing a career of credit and great promise.

# COMBINED DYNAMO AND HIGH-SPEED ENGINE

MESSRS. J. P. HALL AND CO. OLDHAM, ENGINEERS



## COMBINED ENGINE AND DYNAMO.

The following particulars are from the specification for the combined engine and dynamo which is illustrated by the accompanying engraving. The engine has high-pressure double-cylinder to give 7½ indicated horse-power, with 80 lb. steam pressure, at 500 revolutions per minute. The over-all dimensions of the engine and dynamo are 1ft. 9in. by 4ft. 10in. by 3ft. 10in. in height. The dynamo gives 40 ampères at 100 volts at 500 revolutions per minute, the magnets being shunt wound. The engine bed is of box section, with extension for carrying the dynamo, the crank pedestals are cast on, and fitted with phosphor bronze bearings. The stuffing-boxes are long, and the glands screwed on, this form being adopted so that they shall not bind on the rods through carelessness in screwing up unevenly.

The cylinders are 4¼in. diameter by 3in. stroke, lagged with planished sheet steel over non-conducting felt. The standards are of cast iron, of H section, and the pistons are of aluminium steel, fitted with hard cast iron rings and secured to the rods with cones, collars, and Delta metal nuts. The piston-rods and the crank shaft are of steel, of large diameter and great strength, working in long phosphor bronze bearings. The bearing at the armature end is made extra long, and the shaft is provided with a coupling forged out of solid, and on this the fly-wheel is keyed; this bearing is so arranged that it takes up any thrust or pull from the armature. The fly-wheel is made with slots for barring, which are so arranged that if the engine moves suddenly forward when the bar is in, it comes out automatically without risk or shock to the attendant. The connecting-rods are of steel, of the ordinary marine type, and the lubrication is effected by tubes from the main oil box. The governor is of the Pickering high-speed sensitive type, driven by a strap. The guides are of cast iron, secured to the back of the standards. The slide blocks are of steel, are lined with Magnolia metal, and lubricated by tubes from the main oil box. The piston-rods are secured by steel nuts pinned in position on each side of the slide block.

The dynamo, as above mentioned, is shunt wound and has a drum armature. The magnets are of soft charcoal iron, of the single horseshoe type—cores and pole pieces in one—machined all over. The yoke is formed of a separate piece fitting between the extended top ends of the cores and secured in position by bolts. The shunt coils are carried on sheet iron formers with brass ends, the coils being of high resistance, held in position with the brass end rings. The angle plates for carrying magnets are massive brass castings. The armature core is built up of annealed charcoal iron discs insulated from each other, and mounted on a strong steel shaft fitted with key to drive the discs. The winding consists of a sufficient number of turns of insulated copper wire of such sectional area as to give the specified output. The insulation is mica and tape throughout and coated with varnish. The driving power is transmitted to the winding by means of flat driving teeth let into the core and insulated with mica. The commutator is of large diameter, with forty bars of hard drawn copper, insulated with mica, and carried in a cast steel bush, keyed on the shaft. The depth of the bars in the direction of wear is ⅜in. The collecting gear consists of four brushes, two for the positive and two for the negative, held in holders with holding-off catches. The shaft is hard steel, with keys being sunk in, and with half-coupling forged out of the solid to couple to the engine crank shaft.

## RUSSIAN SECRET PROCESS SHOT.

Since writing on this subject in connection with the reports of the trials carried out at Ochta on June 28th and July 3rd and 6th last—see The Engineer of July 6th and 13th—we have endeavoured to learn what we could from persons present at the trials representing English manufacturing firms. We soon ascertained that the shot were kept from inspection before firing as well as after recovery. This bore out our conjecture that a false point had been added on the apex of the shot. We made a sketch, which we did not publish, but sent elsewhere, of the device which we thought was probably employed, namely, a sharp, hard steel point, such as would break into the skin of a treated plate, and probably be shivered and projected to a distance or carried through by the shot. The wood screen might be used to detect if the latter took place. To-day we have a letter from Captain Tresidder, who represented Messrs. Brown at the trial. He encloses a paper containing such data as he was allowed to note, and which are not confidential, which he is contributing to the professional papers of his old corps, the Royal Engineers. Naturally Captain Tresidder was not allowed to see the projectiles, but his impressions acquired when attending the trial and his judgment are of special value. The data as to velocity, &c., are not worth giving here, because striking velocity was not always recorded, and may be said to be fairly represented by the velocities we gave, namely, 1850 foot-seconds for the 6in. plate and 2400 for the 10in. The effects on the plates were also sufficiently given in our previous articles. We now learn, however, the interesting fact that an ordinary and secret process shot fired at a tough homogeneous 10in. steel plate gave in each case about 12in. to 13in. penetration. Seeing that the secret process shot continually perforated the treated plates, while the ordinary shot, under corresponding circumstances, broke up, it is clear that this secret process is effectual mainly in preventing the projectile from shivering against the hard skin of the treated plate. We now come to Captain Tresidder's conjecture as to the secret process projectiles. He considers, without question, that they have false points or caps fixed on their apices. They have been called magnetic shot. We did not take any notice of this word, as we regarded it as a blind. Captain Tresidder views it in much the same way, but suggests that magnetism may have been employed to hold the cap to the smooth apex of the shot, at all events in some instances. He thinks that cap is of wrought iron or very mild steel, for the reasons given by us in The Engineer of July 6th. We have thought it probable that hard steel was used. The account we had received of the effect previously produced by small projectiles on a treated plate, and the absence of recovered fragments, seemed to us to point to this conclusion. Wrought iron we hold to be out of the question, because we know that its normal behaviour is to extend into a ring and to be left in front of the face of the plate. This action might not take place always, but certainly it would occur repeatedly when so many rounds were fired; and wrought iron does not rebound, and so some distorted caps would be seen in front of the target—unless a man were sent out to pick them up, which could hardly escape observation. Captain Tresidder may, however, be correct in believing that a soft steel cap is used, and he mentions in support of his view that from the head of the secret process shot which was embedded in the tough, homogeneous plate, there was visible "a strip of soft iron or steel, as if the cap had been carried into the plate and a strip had been squeezed from it to the rear." He adds that, by an accident, "a momentary glimpse of a certain object was obtained, which was bright, of iron or steel, about 4in. or 5in. long, and pointed at one end; and there can be little doubt it was one of the caps. The point was probably to reduce resistance in flight."

Captain Tresidder suggests a sketch (see Fig. 1) which may be compared with the sketch we made, which we here reproduce in Fig. 2. It will be seen that, considering the secrecy that has been maintained, the accordance of Captain Tresidder's idea with our own is remarkable. There is, however, a distinct divergence in principle between the two. Captain Tresidder's is a pad to break the shock of the hard skin on the point; ours is a sort of temporary wedge to break the skin open instead of allowing the point proper to do so. We know that Captain Tresidder's point would, in a measure, effect the purpose intended, and the strip he saw supports his view. On the other hand, it is so very nearly the old wrought iron cap, that it hardly accounts for the sudden announcement that a new device had been discovered. The first piece of treated plate, with skin perforated or torn by small projectiles, was evidently an unexpected cause of delight. This, we think, was not shown to Captain Tresidder, and this suggests that some new feature and action had been arrived at. The difference, at all events, is small, and the surmise sufficiently promising, we think, to justify a wish that trials could be made with false points or caps, both of soft and hard steel.

FIG. 1

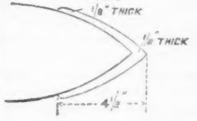


FIG 2

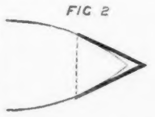

If further evidence as to the existence of a cap or false point is needed it is found in following the fact stated by Captain Tresidder. "After the first two rounds at the 10in. plate, the velocities were chalked on the plate, 2350 (estimated) against the capped shot and 2393 (observed) against the uncapped one. It was asked why the unobserved velocity was not estimated to agree with the observed one, the charges being the same. The reply was that the energies were alike. This meant that the weights were different, as of course would be the case if one shot carried a cap and the other did not. Now, the energy of a 90 lb. shot at 2393 foot-seconds being 3573·9 foot-tons, it is easily calculated that the same energy would require a shot weighing 93·324 lb. if the velocity were only 2350 foot-seconds. This gives about 3⅓ lb. as the weight of the cap. It agrees with the apparent weight of the object seen.

## GERMAN MACHINERY AT THE ANTWERP EXHIBITION.

(*From our Special Commissioner.*)

Thirty years ago, or even fifteen, the machines exhibited by German manufacturers at International Exhibitions were to a great extent copies from British types. There are still some German makers who show no originality, and are content to turn out standard lathes, drilling machines, &c., and to send them to exhibitions; but the number who think out improvements, especially in the direction of saving labour and increasing the speed of production, seems to be increasing.

One of the most ingenious novelties is the Phœnix drilling machine, exhibited by Messrs. Habersang and Zinzen, of Düsseldorf. It is a multiple drilling machine, with six drills driven by the same shaft. Three machines are exhibited, differing in detail; but in all the motion is communicated by a belt to a horizontal drum with different speeds, at the head of the machine, and thence by bevel gearing to a vertical shaft, terminating in a spur wheel. This drives six pinions, each of which turns a drill. The communication between pinion and drill is made by a short shaft, with ball-and-socket joint at top and bottom, so that the drills will work equally well, whether they are directly under the driving pinion or not. As the head of the machine is always at the same height, the drills cannot be raised or lowered; but the table travels instead, and can either be moved automatically at different speeds, or can be raised and depressed by hand. In all the machines the drills pass through a cast iron ring which supports the guides. In one machine the six drills are equidistant from the centre, and one screw serves to move them all nearer to or further from it. This machine is chiefly useful for drilling flanges, and, if desired, it can be made with five or four equidistant drills, instead of six. In another machine there is a separate screw for each drill, so that they can occupy any position with regard to one another within the limits of the guiding ring. In the third machine exhibited the guides are secured to the ring by a square-headed bolt

"THE ENGINEER"

SWAIN ENG.

passing through a slot, so that each drill has to be set by hand, and the table is only moved by a lever, and not automatically. This serves chiefly for drilling hinges, and similar small objects in which large quantities are required to the same size.

The name "Phœnix" seems to be a favourite on the Continent. The Phœnix Company of Ghent has a large installation, which will be described with other Belgian exhibits; and exactly opposite the Phœnix drilling machines the Phœnix printing presses are exhibited. These are shown by Messrs. Schelter and Giesecke, of Leipzig, and consist mostly of presses for colour printing. Several small improvements have been introduced into these machines. For instance, in one pretty little press, which is engaged in producing Messrs. Schelter and Giesecke's artistic circulars, there is a scale by which the degree of pressure can be regulated, and four distributing rollers, which oscillate in such a manner that two give ink by the downstroke and the other two by the upstroke.

At an adjoining stand Messrs. Gilgenberg and Co., of Cologne, exhibit a new joist-cutting press, by which they can cut the ends of eighty joists per hour. The general arrangement is that of an ordinary hydraulic press; but the peculiarity consists in the shape of the cutters, and in the method of cutting. Six knives are used; one each for the top and bottom, which vary according to the section of the joist, and four for the sides, which serve for all sections. These side knives are of triangular form, so that when one edge is worn they can be turned. The top and bottom cutters can be changed in half a minute when it is desired to shear a different section of joist, and the side cutters are set to the corresponding width in the upper and lower part of the machine, so that when the pump is started the piston forces all six into the joist, which is thus cut on all sides. The largest machine exhibited will cut joists up to 18in. deep; and a small hand-power machine is also shown, which will cut up to 6in. The same machine can be used for channel, angle, and T iron; but it is doubtful whether it would for these have any advantage over ordinary shears—especially as the knives, cutting the metal on all sides, leave a sharp instead of a square edge.

Mr. Erhardt, of Wolfenbuttel, Brunswick, has a good arrangement for oil extraction, consisting of three hydraulic presses, a preparatory press, a trolley, and a hydraulic pump. Instead of bags, steel cylinders are used. Those shown are of $1\frac{3}{8}$in. metal, $17\frac{3}{4}$in. internal diameter, and 2ft. $7\frac{1}{2}$in. deep. They are drilled with 16,000 holes, $\frac{1}{16}$in. diameter at the outside, tapering to about $\frac{1}{100}$in. on the inside. The three hydraulic presses are in a row; the rails for the trolley run just in front of them. The empty cylinders are placed on the trolley, which stands under the preparatory press; they are there filled with the linseed, or other material to be treated, and the contents of the cylinder slightly pressed, to consolidate them. The trolley is then run forward, the cylinder is brought by a lever under the hydraulic press, a circular shield of sheet iron is dropped round it to catch the jets of oil which spurt out, and a pressure commencing at 450 lb. to the square inch is applied. The exhibitor states that the presses can, if necessary, work up to 4500 lb. to the square inch. The trolley will accommodate two cylinders; the one containing the pressed grain is removed, and another that has been refilled is substituted. The first one is then run back to the preparatory press, which pushes the cake of compressed grain into a receptacle in the trolley. One man is thus able to fill, empty, and keep three presses constantly at work. Fifteen tons of linseed can be treated daily in the three presses exhibited, and other materials in proportion.

One of the most compact ice-making machines I have seen is exhibited by the Hallesche Maschinenbau Austalt, formerly Messrs. Vaas and Littmann. The medium employed is liquid carbonic acid. The machine exhibited will produce 2 cwt. of ice per hour; but others have been made on this principle, with an hourly production varying from 11 lb. up to two tons. All ice-making machines may be said to consist of three essential parts, the compressing plant, the refrigerator, and the condenser. With carbonic acid a smaller pump is required than when ether, ammonia, or sulphuric acid is used; in the machine shown, the pump, which is double-action, drawing the carbonic acid gas from the refrigerator, compressing it, and forcing it into the condenser, has a piston 3in. diameter, and the length of stroke is 10in. The refrigerator, like that of most ice-making machines, consists of a tank containing brine, into which cells containing fresh water are lowered; and from which, when they are frozen, they are raised by a small overhead traveller. Wrought iron coils, filled with liquid carbonic acid, pass from the condenser to this tank, and round each a group of cells. The condenser is a wrought iron coil, made in a single piece, in which the carbonic acid, which has assumed a gaseous form in giving up its cold to the brine, is again liquefied, partly by pressure from the force pump, and partly by the surrounding cooling water. The cylinder of the compressing pump has an outer case with an air-space between, and a special patent valve for the carbonic acid is used. Of course loss in carbonic acid cannot be detected by smell, but the exhibitors say that there is practically none; and in any case it has the advantage over sulphurous acid, that it is cheap, and that if any should escape, it cannot contaminate the water, nor injure the machinery.

A new arrangement for driving centrifugals is shown by Messrs. Heine Brothers, of Viersen. A small engine, making 250 revolutions per minute, has a horizontal fly-wheel and a disc crank. The fly-wheel runs in a groove in the bed-plate, and has a flange on its lower edge. A copper pan, or "hydro-extractor," pierced with holes in the usual manner, is surrounded with an iron casing and mounted on a vertical shaft. This pan is 24in. diameter and 13in. deep, and on the shaft is a pulley 6in. diameter. A belt passes round the fly-wheel and round this pulley, so that the centrifugal is driven at 1000 revolutions a minute, with no gearing and only one belt.

Messrs. Fleck and Sons, of Berlin, exhibit band saws and various descriptions of wood-working machines, but their chief novelty is an automatic saw sharpener. This machine will serve equally well for straight or circular saws, and will cut any description of teeth. The cutter is an emery wheel, which is mounted on a guide set in a circular frame. An index on this frame shows the angle to which the wheel is set, and on the top of the frame is an arm with a balance weight, to regulate the pressure of the wheel on the saw. A guide on the tool holder runs on a plate cut to correspond with the form of tooth desired, so that when once a form of tooth has been chosen, the use of the corresponding guide or template will always ensure its exact reproduction. A small arm—which can be set to any desired length—pushes the saw forward as soon as the wheel has finished cutting a tooth, so that when the attendant has set and started the machine, he does not need to touch it again till the saw is finished. A small fan at the base of the machine is connected with an opening behind the emery wheel, so as to carry off the dust and prevent it from injuring the machinery. In its ordinary working position the centre of the emery wheel is exactly above the centre line of the saw, so that all teeth are alike; but when it is considered desirable to have teeth sharpened alternately on the right and left sides, the whole upper part of the machine can be made to travel by means of an excentric. By this means the emery wheel cuts the teeth, first on one side and then on the other. The length of stroke of this excentric can also be regulated, so that the machine is completely automatic.

Messrs. Fleck and Sons also exhibit an automatic grinder, for sharpening the cutters of planing machines. Like the saw sharpener, this consists of an emery wheel, which can be set at any angle. Another exhibit is a circular saw with movable table. The table can be set to any angle by an index below, and then clamped in position whilst the saw blade remains vertical. They also show a moulding machine for working on all four sides—in which the arrangement of the cutters is a little different to those of English make—some band saws, and a thicknessing machine. This will cut to an exact thickness boards up to 20in. wide, and they have made machines to take double this width.

The gas and petroleum engines shown are very numerous. Most of the latter are of German make, though Belgium and France are also well represented. The largest engines shown in motion are those of the Dresdener Gas Motoren Fabrik, already described as driving the Gould's pumps for the water supply of the building. Two "Capitaine" engines, as illustrated in The Engineer of July 20th, page 63, are exhibited by Mr. Ph. Swiderski, of Leipzig. The one is a 10-horse power vertical, the other a 4-horse power portable on a low frame.

Messrs. Körting Brothers, of Hanover, are running dynamos coupled direct to the engines. One of their exhibits is a 6-horse power gas engine, making from 180 to 200 revolutions per minute, and driving a dynamo giving 50 amperès, at 65 volts. Electric lights, both arc and incandescent, are connected to the dynamo, so as to show that the slow speed does not interfere with the steadiness of the light. The engine is water jacketed, the cylinder being cast separate from the jacket, and inserted in it. The water flows round the cylinder as long as the engine is working, but when it stops the jacket is self-emptying, so that there is no risk of water being left in it to freeze in winter. The governor has four balls, and is somewhat of the Buss type; it is on a horizontal shaft by the side of the machine, is cased in, and very compact. Messrs. Körting have made engines and dynamos coupled on this system up to 60-horse power with single-cylinder engines, and up to 300-horse power with two cylinders. Another exhibit is a 2-horse power petroleum engine, in which the petroleum to be used in the lamp first passes in a small iron pipe over the flame, to convert it into gas. They also show some valves, radiators and pulsometers, and a pump for boiling water, which is, however, not working.

Messrs. Grob and Co., of Leipzig, also exhibit petroleum engines, including a 6-horse power portable, which took the gold medal last May at an agricultural show at Meaux, near Paris. The most interesting part of their exhibit is a full-size model of the steam launch Princesse Clementine, shown in section. The novelty in this exhibit consists in the arrangement of the levers on the screw shaft. Of these there are two, both aft and close to the rudder. One puts a friction clutch in and out of gear, thereby disconnecting the screw from the engine; the other reverses the three blades of the screw. The exhibitors say that, by reversing the screw blades, the boat to which this engine belongs has been made to stop in her own length.

There are other interesting German exhibits, of which I must reserve an account till next week. The jury met cn the 26th ult., and commenced work on the following day.

## THE INSTITUTION OF NAVAL ARCHITECTS.

Our account of the proceedings at the Southampton meeting published in our last impression included those of Wednesday. The first paper read on Thursday morning was by Mr. F. Gross on "Recent Experiences with Cylindrical Boilers and the Ellis-Eaves Suction Draught." This paper we publish in full on page 112.

The discussion was opened by Mr. F. Marshall, who said that his firm had fitted two vessels, and the results obtained were very satisfactory. Mr. Gross' figures were accurate. At the Cardiff meeting he had been asked to speak; but he did not then, for lack of experience, feel free to express an opinion. Explain the matter how one might, the fact remained that induced draught was no doubt better than forced draught. The result was probably due in part to the fact that the combustion was more evenly distributed over the grate with the former. Holes did not burn in the fire; certainly the boilers gave no trouble, and the owners of the two ships referred to were so satisfied that they had ordered a third. There were, of course, drawbacks, as there always were to every change for the better. There was some difficulty to be feared about the fan engines, which had to run continuously for long periods at 320 revolutions per minute. The Perthshire had two fans, but in larger ships as many as five were required. Very close supervision was needed to keep these fan engines running for fifty or sixty days without stopping, night or day. Smaller boilers could no doubt be used, and weight saved; but against this must be placed the weight of the fans, engines, &c. The air was sent into the furnaces at temperatures varying between 220 deg. and 270 deg., which last had been got in the Berlin.

Sir Edward Harland spoke at some length, but he appeared not to have followed the paper very closely, and for a minute confused the drawings of Mr. Terry's paper on the ventilation of oil steamers, published in our last impression, with Mr. Gross' drawings. He held that while it was possible to attain very high rates of combustion with square grates in torpedo boats because water-pans could be placed beneath the bars, it would be impossible to do this in circular furnaces 3ft. 6in. diameter or thereabouts, because, in the first place, much smoke would be made; and, secondly, because the fire-bars would certainly be melted down, because a water-pan could not be used. Again, he held that seeing how slowly air took up heat, it would have been much better to use the air-heating tubes for heating the feed-water. As to induced and forced draught, he could not see that there was any difference. It came to the same thing in the end whether he pulled a man's nose or applied gentle persuasion with his foot behind. The man had to move. For his own part he preferred a closed stokehold.

Mr. Thornycroft followed. He pointed out that shipowners wanted economy in coal, and it appeared to him that just the same result would be obtained if instead of heating the air the same amount of surface had been added to the boiler. In torpedo work, very high rates of combustion were attained, but a water pan was used, and the force with which the air entered was so great that he had known the water to be licked up by it and carried on to the bars. His own experience was that forced draught gave no trouble, while the fire-rooms were really quite cool, and more easily kept cool than the engine-rooms.

Mr. Fothergill agreed generally with Sir E. Harland. If the heating surface in the air heater was added to the boiler, the result would be just the same. The ordinary cylindrical furnace was not adapted for fierce draughts. It had to be filled nearly to the top. The cool crown plate would check combustion and cause smoke. The great advantage of the water-tube boiler was that it gave a big space for combustion. But there was no cause for apprehension about fan engines. He was using engines which ran at 700 revolutions per minute, for thirty consecutive days without difficulty. Forced draught would become the rule instead of the exception.

In reply, Mr. Gross said that he was able to answer fully all the questions that had been asked. The paper which he had just read must be taken as an addition to that read last year at Cardiff by Mr. Ellis, and the drawings on the wall were those which had been used at Cardiff to illustrate the apparatus.—These drawings were reproduced on a small scale in our pages at the time.—No doubt many of the questions now asked were put because Mr. Ellis' paper had been forgotten. To begin, however, with Sir Edward Harland's questions. He might say that that gentleman was quite correct in assuming that difficulties would be encountered with fire-bars; indeed the trouble was greater than Sir Edward had supposed. On one occasion, for example, they had melted a set of fire bars in half an-hour, and yet they could now run for seventy-five days, and leave the bars quite good. The whole difficulty had been got over, as explained by Mr. Ellis, by raising the fire-bridge end of the bars 2in. higher, instead of dropping them 2in. lower than the door end. Why or how this had the required effect Mr. Gross did not stop to explain; he contented himself with stating the fact. It might be, he said, that if they exceeded a rate of combustion of 60 lb. per square foot per hour there would be trouble; but that was fast enough, and up to that rate there was no trouble of any kind. As for the fans, it was a proved truth that at any chimney temperature not exceeding 600 deg. they lasted perfectly well and gave no trouble. The boiler tubes they used were $3\frac{1}{4}$in. in diameter, with a baffler, or distributor, resting on the Serve ribs, and the result was quite satisfactory, for in each of these tubes there was 75 per cent. more effective surface than in a plain tube of the same diameter and length. As for the general arrangement, he liked one fan for each boiler or for each end of one double-ended boiler, because if a fan engine broke down there was only one end of a boiler rendered inefficient, and the others could take up the work, and it must be remembered that even if all the fans broke down the ship could still steam well with natural chimney draught. As to the weight of the air-heating tubes, they were only of 12 or 14 guage, and did not weigh anything like what an equal amount of boiler surface would weigh. Very careful experiments showed that whether the water was heated, as suggested by Sir Edward Harland, or the air was heated, the result was just the same. As for weight, the big Atlantic and other liners now carried as much as 3000 tons of coal, surely the chance of saving 300 tons on this was worth trying for. It was often said that air took up heat very slowly; that was not his experience. The velocity of the air in the heating tubes was 2000 feet per minute, and it was easy to see that the air was in contact with the hot metal for a very short time. Nevertheless, it was easily heated to 300 deg. Sir Edward Harland had asked why certain blanks in the tables had not been filled. The answer was that the information wanted could not be given because of causes which had augmented the consumption of fuel or upset the direct progress of events. Thus, in one case, a breakdown occurred, and the engines had to work compound instead of triple. In another case the propeller lost a blade. The table contained nothing but ascertained facts. The high economy realised was due to the fact that, although the boiler had nominally only 28 square feet of heating surface to one of grate, yet that really, because of the Serve tubes, there were nearly 50 square feet.

A vote of thanks was passed unanimously, and then Mr. Terry read his paper on the ventilation of oil steamers, which we published last week. The discussion which followed was very short. No one had any fault to find. A few questions were asked, and Mr. Martell called attention to the curious fact that short as was the period which had elapsed since the carriage of oil in bulk had been suggested, yet that cargo such as rice was now carried in the oil tanks, and that even tea was about to be carried. This could only be done by the aid of a method of ventilation so efficient that when the oil had been pumped out, every trace of the gas should be pumped out also.

Mr. Terry replied in a few words, and a vote of thanks was passed. This virtually concluded the business of the meeting, and the members then proceeded to the Paris, where they were sumptuously entertained by the directors the International Company. The Paris, we may add, had only got into dock at 5 a.m. the same day.

In the afternoon a garden party was given, as already stated, at Bassett, by Sir Stuart and Lady Macnaghten, and in the evening a dinner at the Royal Victoria-rooms by the South-Western Railway Company.

On Friday morning a large number of the members proceeded in a special saloon train, provided by the South-Western Railway Company, to Portsmouth Dockyard, where a dockyard train was in readiness. The members on their arrival were conducted over the several shipbuilding and engineering shops. They visited H.M.S. Majestic, first-class battleship of 14,900 tons, 10,000 indicated horse-power natural draught, 12,000 forced draught, in process of building. Also H.M.S. Sultan, third-class battleship of 9290 tons, 6500 indicated horse-power natural draught, 8000 forced draught. They then visited the main pumping station, electric shop, torpedo and gun mounting stores, and other works of interest. By special permission of the Lords of the Admiralty, they then visited H.M.S. Revenge, first-class battleship, 14,150 tons, indicated horse-power, 9000 natural draught, 13,000 forced draught, now ready for sea, and witnessed the working of her heavy guns.

On leaving the gun mounting store, the members were carried by the dockyard train to the jetty, where, a little after 1 p.m., the Jersey steamer, Frederica, took them on board. The Frederica had left Southampton at noon with a large party of ladies and a few gentlemen, who did not care to visit the docks. Luncheon was served while the ship lay alongside the pier, and about 2.30 p.m. she started in beautiful weather for a trip round the Island. She reached Southampton about 6 p.m., having run nearly 60 miles in three and a-half hours, without the slightest attempt at pressing her. Indeed, she travelled much faster than was desired by those on board.

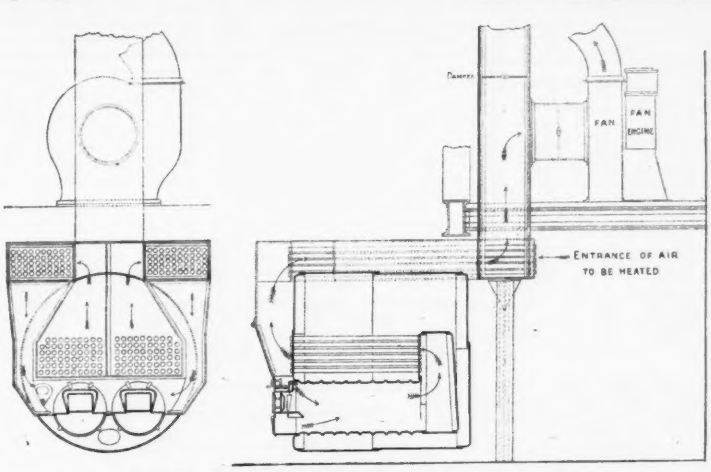
So ended a meeting in every way a success, for although the Tantallon Castle was hospitably thrown open by Sir Donald Currie, and a tender was provided to convey visitors to her, not many availed themselves of the opportunity on Saturday morning. Very great credit is due to all concerned. The hospitality extended to the Institution was in every respect cordial, ample, admirably planned and admirably carried out. Thre was no hitch from beginning to end, and Mr. G. Holmes, the secretary, left nothing that fell within his province undone to secure the great success attained.

## RECENT EXPERIENCES WITH CYLINDRICAL BOILERS AND THE "ELLIS AND EAVES" SUCTION DRAUGHT.[*]

By Mr. F. Gross.

At the last summer meeting Mr. Ellis read a paper on "Some Experiments on the Combination of Induced Draught and Hot Air Applied to Marine Boilers fitted with Serve Tubes and Retarders." So much special attention is being given to boilers for ships at the present time, that it will perhaps interest the members to be informed of the experience which has been gained to date with this system applied to marine boilers on land and at sea. The boilers which have been working longest with this combination are at the Atlas Works, Sheffield. Nos. 7 and 8 are now three years old; Nos. 9 and 10 are two years old; Nos. 11 to 16 have since been gradually added. These ten single-ended marine boilers, placed together in one shop, furnish part of the steam required by the works, and are at work day and night. Their ordinary work is to maintain a regular combustion due to 3in. vacuum at the fan inlets, corresponding to a combustion of 35 lb. to 37 lb. per square foot of grate, which is uniformly 5ft. 8in. long in all the boilers. For short periods, at certain intervals during the day, the quantity of steam required is appreciably greater than the regular quantity, when, by increasing the number of fan revolutions, the rate of combustion is immediately raised to 40 lb., 45 lb., 50 lb., or even 60 lb. per square foot of grate, and as promptly reduced when the demand for the extra steam has passed away. It will be evident that, unlike boilers with natural draught, the boiler is the constant quantity, whilst the draught is varied largely according to the requirements for the time being.

For the purpose of obtaining data on suction-draught fans, different diameters and widths are used. Moreover, some fans work one boiler only, and are placed above the boilers; others work two boilers, and are placed on the ground floor, sucking the gases downwards, and discharging them into short funnels, which just clear the roof of the building. The success of boilers Nos. 7 and 8 led to the construction of Nos. 9 and 10, and the satisfactory experience with the four, to the subsequent further six, partly for the sake of space, partly for economy and absence of smoke. The ten boilers, 10ft. 6in. by 10ft. 6in., displace three to four times as many Lancashire boilers of about 28ft. by 6ft. 6in., whilst the evaporation per pound of South Yorkshire coal is 9 lb. actual from cold feed—or 10½ lb. from and at 212 deg.—when burning at 30 lb. per square foot of grate, or 8½ lb. actual feed—or 10 lb. from and at 212 deg.—when burning at 45 lb. per square foot of grate, as against 6½ lb. actual from cold feed in the Lancashire boiler burning at 19 lb. per square foot of grate with a chimney 130ft. high. Very recent careful examination of the boilers shows that the Purves flues, tube plates, and Serve tube ends in the oldest are as good as new; and it is worthy of special note that the feed-water comes cold from the river, unfiltered, and that the draught is not shut off when the doors are opened for firing, slicing, or raking. The dampers are used only when the fires are being cleaned—every six hours. The fans likewise continue to work satisfactorily, as anticipated, because the gases when entering the fans do not exceed 450 deg. at the highest rate of combustion, the air heated by the waste gases then entering the furnaces at 320 deg. For these boilers, owing to the steam pressure being as yet unavoidably only 50 lb. per square inch, the fan engines are simple engines.



Boiler with Ellis and Eaves' Hot Air and Suction System

The International Company's steamship Berlin—better known under the old name of the Inman Company's City of Berlin—was the first steamer fitted with the draught, as conveniently as the position of the eight single-ended boilers facing the centre longitudinal line of the ship permitted. The air-heating tubes had in this case to be placed across the front instead of lengthwise of the boilers, offering consequently more obstruction, with less effective heating surface, than when placed in the usual way. She has been working hard since March 1st, 1893, with satisfactory results, and has burnt at an average rate of 26 lb. per square foot of grate, 5ft. 3in. long.

The same owners adopted this draught for the two new steamers built in this country and recently completed, viz., the steamship Southwark, by Messrs. Denny, and the steamship Kensington, by Messrs. J. and G. Thomson, Clydebank. They are twin-screw sister ships, 480ft. long by 57ft. wide by 40ft. deep. The main engines are quadruple expansion, and intended to develope 7000 indicated horse-power in each ship at trial trip. The Southwark has two double-ended main boilers, 15ft. $9\frac{3}{16}$in. mean diameter by 21ft. 8¾in. long, and one single-ended, 15ft. $9\frac{3}{16}$in. mean diameter by 11ft. 1in. long. Each of the five boiler ends has four Purves furnaces 3ft. 4in. inside diameter, grate bars 5ft. 9in. long. Total grate surface, 383 square feet. Total heat-distributing surface inside the boilers, 12,285 square feet. Working pressure, 200 lb. Each boiler-end has one exhausting fan 7ft. 6in. diameter, and separate single-acting engine by Messrs. Sturtevant, of Boston, United States, these engines being used freely in the International Company's steamers. The Serve tubes in the boilers are 3¼in. outside diameter. At the trial trip, with a displacement of 12,300 tons, she easily developed the expected power, and gave the mean speed of 16·3 knots. On her station she has been running four round voyages, Liverpool to Philadelphia, almost entirely with the two double-ended boilers only at work, with an average combustion of 27½ lb., which will gradually be increased. In the Kensington the boilers are slightly longer, the double-ended 21ft. 7in. and the single-ended 11ft. 5in. The total heat-distributing surface inside the boilers is slightly less, viz., 11,672 square feet. The number and size of Purves furnaces, the length of grate bars, and diameter of Serve tubes are the same as in the Southwark. At the trial trip, with a displacement of 12,400 tons, she gave a mean speed of 15·8 knots. She has run one voyage West so far.

Whilst the foregoing steamers are giving experience for the Atlantic service, two other large steamers are doing the same for the long voyages to and from Australia. Messrs. Turnbull, Martin, and Co., London, in the Australian dead meat trade, have this combination draught in their new sister ships, Perthshire and Buteshire, built by Messrs. Hawthorn, Leslie, and Co., Newcastle. These ships are 435ft. long over all, 54ft. wide, and 32ft. deep. Displacement when fully loaded, 12,000 tons. For the power of 3000 indicated horse-power in each ship there are two single-ended boilers, 15ft. 6in. diameter by 12ft. long, each with three Purves furnaces, 3ft. 9in. inside diameter, and grate bars 5ft. 9in. long. Total grate surface in each ship, 127 square feet. Heat-distributing surface within the boilers, 4770 square feet in each ship. Working pressure, 160 lb. The fans and triple-expansion fan engines are of Messrs. W. H. Allen and Co.'s make. Each ship has completed one round voyage to Australia and back. On the outward voyages, with an average indicated horse-power of main engines of 2450 to 2500, the coal consumption averages about 26 lb. per square foot of grate. On the home voyage, requiring considerable extra steam for the large refrigerating machinery, the Perthshire averaged a combustion of 31½ lb. over fifty-nine consecutive days, and the Buteshire 27½ lb. per square foot of grate over fifty-six consecutive days. The coal consumption of Newcastle small coal on the outward voyages averages 1·345 lb. per indicated horse-power of main engines. This includes the power required by the fan engines. With South Wales coal the consumption of main engines will therefore be under 1·3 lb. per indicated horse-power, after finding the power for the fan engines. Although the boilers of the Perthshire had been continually under steam for seventy-five days, being worked for fifty-nine days at this, for Australian voyages, unprecedented rate of combustion, the furnaces, tube plates, tube ends, and the fans were found in good order on arrival London. These owners in are fitting the draught arrangement to a third sister ship, the steamship Banffshire, now building by Messrs. Hawthorne, Leslie, and Co.

Briefly summarised, the experience to date may be considered to have established a rate of combustion on a grate 5ft. 9in. long of 30 lb. to 60 lb. in marine boilers on land, and of 26 lb. to 31½ lb. at sea, in the Atlantic and Australian services, without troubles to furnaces, tube-plates, tube ends, fans and fan engines, accompanied by an appreciable economy compared with boilers of the same size with plain tubes working with natural draught at half the rate of combustion. The main factor in the economy is, of course, the Serve tube in combination with the retarder, because the Serve tube has on an average at least 75 per cent. more heat "absorbing" surface than the same diameter of plain tube. The result is that at the highest rates of combustion, and with 3¼in. diameter tubes—permitting natural draught to be readily used—the gases, when they reach the smoke-box, do not exceed 700 deg. The heat absorbing surface of the air-heating tubes completes the economy, the gases reaching the fans cooled down to 300 deg. to 400 deg., having heated the air to from 200 deg. to 300 deg., according to the rate of combustion and amount of absorbing surface. Against closed stokehold forced draught, burning at the same rate of combustion with plain tubes, the weight of the boilers with this system will be greater, but there is a considerable net saving in weight for other than short cross Channel voyages through the economy in fuel, which is naturally greatest against closed stokehold cold air draught. At a combustion of 30 lb. per square foot of grate this economy will be at least 15 per cent. Against Mr. Howden's latest practice the loss of weight is trifling, being practically only the extra weight of the ribs in the Serve tubes and of the greater surface of the air-heating tubes, and these produce a distinct advantage in economy in fuel of at least 7½ per cent. In a number of steamers working with Mr. Howden's draught, the substitution of Serve tubes for plain tubes has at once given an economy of 10 per cent., and it will be conceded that the horizontal air-heating tubes in the suction draught will be more effective than vertical tubes. Even with natural draught, with a funnel height of 75ft. or more, the Serve tube has proved in a considerable number of vessels that it gives an economy of 10 per cent. over plain tubes in the same boilers, and the special advantage of this suction-draught combination is to give the same economy when burning at twice the rate in half the number of boilers, or to make the steam as economically as is now done with natural draught and plain tubes when burning at three times the rate in one-third the number of natural draught boilers.

Taking, therefore, boilers and coal together, this system requires in reality for moderate and long voyages the least weight of cylindrical boiler for a combustion of 25 lb. per square foot of grate and upwards; and, as the action of the suction draught is to heat the boilers more uniformly the higher the rate of combustion—therefore the opposite of forced air pressure draught—it is probable that we shall gradually see the boilers reduced more and more in size, and the rate of combustion at sea increased to 40 lb., 50 lb., and upwards per square foot of grate. Electric motors with small fans will assist in this direction, and the economy, safety, and comfort of this system in working are strong recommendations for large passenger and cargo boats, whilst for warships the power to do away entirely with smoke, and even with funnels, should not be without importance. The accompanying table gives the principal data for the five ships grouped together for handy reference.

[*] Paper read before the Institution of Naval Architects on the 26th July, 1894.

## THE DESIGN OF MAIL STEAMERS, WITH SPECIAL REFERENCE TO THEIR USE FOR WAR PURPOSES.*

By Professor J. H. Biles, M. Inst. Naval Architects.

The selection of a subject for a paper for the summer session at a port like Southampton naturally involves, in a greater or less degree, the consideration of mail steamers; and the contiguity of the arsenal of Portsmouth, replete as it is with naval war material of all kinds, cannot but suggest the question of how much assistance mail steamers may be to the Navy in time of war. It is evident that the ordinary mail steamer of over 5000 tons, with a sea speed of over 16 knots, has a sea-keeping power and a sea-going speed not inferior to many warships. For carrying despatches or for scouting these qualities are necessary, but this work can at the best only relieve warships from such duties. It is submitted that it is a question of national importance, and one which is deserving of consideration and discussion by this Institution, whether mail steamers may not be so designed that they may in time of necessity leave their peaceful business of carrying mails and passengers, and take a place among the fighting ships of the Navy, where they will be capable of doing work similar to what is expected of our first-class cruisers. It is with the object of raising this question, and indicating some of the points to which attention may be given in designing mail steamers with this object in view, that this paper is submitted to the Institution.

While efficiency for commerce is the first consideration for the shipowner, it need not be the only consideration, and if, in considering what is best for commercial requirements, there may be alternative methods of equal value open to the ship designer, that which is of greater use for war purposes ought to be, and probably will be preferred. As some justification for this statement, one has only to refer to the papers read by Mr. James Dunn, in 1882 and 1883, on merchant steamers and bulkheads, to see what shipowners did when some of the simplest requirements for war purposes were pointed out to them. The greater subdivision of these merchant steamers was expected to have detracted somewhat from their commercial efficiency. This expectation was probably only realised to a small extent, for at the present time vessels are successfully running with much greater subdivision than that thought desirable ten years ago. It is therefore evident that shipowners can adapt their ships so as to meet some of the requirements for war purposes without detracting unduly from commercial efficiency.

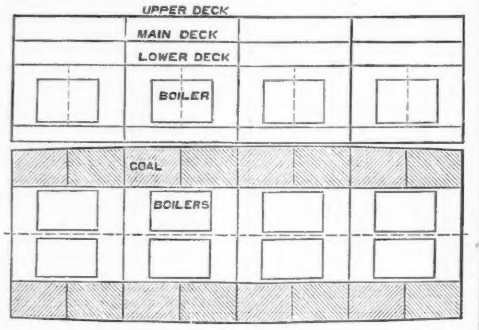

FIG. 1.

But there is obviously a limit to the amount which can be done by the shipowner for this purpose without involving him in an extra first cost, which can give no commercial return, but which may, on the contrary, be a constant cause of loss. It is, however, at first desirable to see what can be done to make a mail steamer so that she can readily be changed into a warship, and then to see what such changes in the design will involve in the commercial efficiency of the vessel, and how the losses due to such changes can be met by the country in return for the services such a vessel can render in time of need. Another way of putting the question is to ask whether it is necessary that all the warships of a country should be unremunerative in times of peace, or whether some of them may not be doing useful service, such as carrying mails and passengers. It is desirable first to consider in what respects, and in what manner, an ordinary mail steamer should be modified to make her suitable for war purposes. As far as I understand the requirements of the Admiralty for merchant ships which may be used for war purposes, they are: (1) The ship must be divided so that when one compartment is in free communication with the sea the ship will not sink; (2) that the decks shall be capable of being readily strengthened so as to carry guns.

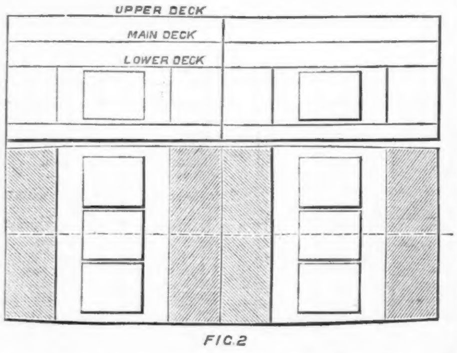

FIG. 2

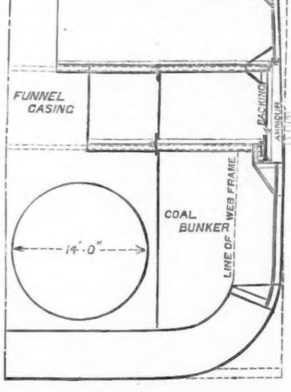
The points which may be considered in a mail steamer with reference to her suitability for war purposes may be taken broadly to be: (1) Sub-division; (2) capability of being protected by armour or coal; (3) facilities for placing and working guns; (4) speed; (5) coal endurance. First, as to sub-division, it is usual to fit large mail steamers with a double bottom throughout, though in some notable cases this has not been done. This double bottom is not, as in the large warships, carried up the side, but is usually stopped before the turn of the bilge. Hence, for any purpose of use in war time, for protection against guns or torpedoes, it need not be considered. Other longitudinal sub-divisions, such as middle-line bulkheads, fore and aft coal bunker bulkheads, may be of great use. Starting on the assumption that coal can be made use of as protection, it is obviously desirable to put the coal where it can give protection—viz., in the vicinity of the water-line, at the sides of the ship.

A very common arrangement of bunkers is to have the coal in transverse blocks, extending from side to side of the ship, the boilers extending from side to side in adjacent compartments. This arrangement is shown in Fig. 2. This method does not give a maximum of protection for a given amount of coal. To ensure the maximum of protection there should be no transverse block, except, perhaps, one at each end of the machinery space. The arrangement of bunkers which gives the best protection is that where the boilers are at the middle line, and the coal is at the sides. The longitudinal bulkheads forming the sides of the bunkers can be continuous for the length of boiler space, and in some ships this side bulkhead can be carried through the engine space also. The axis of the cylindrical boiler is almost of necessity placed fore and aft, especially if the boilers are double-ended. This arrangement admits of further subdivision if the beam of the vessel and the diameter of boilers be so chosen in relation to each other that the bunkers on each side of the ship shall contain all the coal necessary for the voyage for the boiler between them. Then each boiler end may have abreast of it all the coal that is necessary, and the bunker space abreast of the boiler may be divided by a transverse bulkhead between the ship and bunker sides, through which there need be no opening. Such an arrangement is shown on Fig. 1.

The space occupied by these two alternative methods is not very different, the superiority of one over the other depending upon the amount of coal carried. The arrangement shown in Fig. 1 avoids coal passing at sea, and admits of ready shipment of coal in port with a minimum of labour in stowage. The question of rapidity of coaling in port is dependent partly upon the number of openings through which coal can be passed, and partly upon the facility with which the coal will run, so as to fill the bunkers with as little assistance as possible from the coal heavers. Both these considerations are best fulfilled by the long side bunkers when they are of considerable size, as in Fig. 3. Even if the relation between beam of ship, diameter of boiler, and length of voyage cannot be so fixed as to allow all the coal necessary for each boiler to be carried abreast it, the arrangement in Fig. 3 is preferable, though it will be necessary to carry additional coal either on the deck above the boilers or in transverse bulkheads between the boilers. It is, however, worth very serious consideration whether the beam of the vessel and the diameter of the boilers should not be so related to each other that the capacity of the bunkers abreast of the boilers should be sufficient for all the purposes of the voyage. The material necessary to form bunker bulkheads would be placed so as to be of structural strength greater than in the other way. The bunkers would be a large cellular structure at the side of the ship, and would form a protection of the best kind against the effects of collision.

Probably this amount of subdivision of coal bunkers and boiler-rooms is the greatest that can be afforded, if commercial efficiency only is taken into account. Efficiency for war may be kept in view by placing a row of horizontal stiffeners or beams between the ship's and bunker sides at a distance of 8ft. or 10ft. below the water-line, so that in war time a flat of wood or iron could be readily laid upon these beams with a view to further subdivision and to a retention of the coal in the vicinity of the water-line. The stringer of keelson at ship's side at the line of these stiffeners could be made water-tight, either in the usual way by staple angles, or so arranged that when the flat is laid it could be readily made water-tight with cement. In the largest vessels the lowest continuous deck is not far from the water-line, and is sometimes below it. As this deck is required for passengers, the space amidships is too valuable to give to coal bunkers. Even in this case, however, efficiency for war may be kept in view, and without interfering with commercial efficiency provision for protection may be made. It is quite common to have partial bulkheads several feet in width between the decks for purposes of structural strength. Usually the line of the inside edge of these bulkheads is arbitrarily chosen, and the position of this line in each bulkhead has no relation to the adjacent one. If, however, the inside edges of these bulkheads be arranged all in one plane, say 10ft. from the ship's side, it would be very easy to run a line of plating on this plane in war time, so as to form an inside line of further longitudinal subdivision. The lower and main decks are usually plated, though not usually caulked. If, when the ship is building, the lower deck be caulked, and an angle, with its flange standing some 3in. above the wood planking be fitted, and if holes be punched in this angle, as well as in those forming the stiffeners on the inside edge of the partial bulkhead, and if similar arrangements be made on the under side of the main deck beams, there will be all the necessary means of connecting a line of plating, and thus forming this line of subdivision at a most important part of the ship. If the further precaution is taken of making the partial bulkheads themselves water-tight at the lower deck, the side of the ship in the vicinity of the water-line can be most readily subdivided into a large number of small compartments, and the ship's liability to sinking from the effects of gun fire be considerably reduced. This method of subdivision may be carried out as far as such partial bulkheads extend, and as these bulkheads add very considerably to the strength of the ship, it may not be too much to say that the arrangement for such subdivision in war time should be made for three-fourths of the whole length of the ship. It is probable that this amount of subdivision is as small as is practicable for rapid handling of coal at sea.

FIG. 3



(*To be continued.*)

## AMERICAN ENGINEERING NEWS.

(*From our own Correspondent.*)

*Fast cruiser for the United States navy.*—The new triple-screw cruiser Minneapolis, built at the Cramp shipyards, was given a trial trip of 88 miles on July 14th, developing an average speed of 23 knots for the entire distance, and a maximum speed of 25·42 knots. The machinery worked to perfection, the boilers carrying 150 lb. pressure and the engines making 124 to 134 revolutions per minute. The trip was made in the open sea, starting from near Boston. The outward run of forty-four miles was made in 1 hour 55 min. 18 sec., an average of 22·90 knots. The turn was made in 18 min. 34 sec., and the return trip of forty-four miles was made at the rate of 23·20 knots. The Minneapolis is a sister ship of the Columbia, whose trial trip occurred a few weeks ago—page 576 of The Engineer. She is 412ft. long, 58ft. beam, draws 22ft. 6in. of water, has 7350 registered tonnage displacement, and has cost 2,690,000 dols. She was specified to have a speed of at least 21 knots. She has three sets of triple-expansion three-cylinder engines, developing 21,000 indicated horse-power at 129 revolutions per minute. There are eight double-end main boilers in four water-tight compartments. They are constructed of steel for a working pressure of 160 lb. to the square inch, and have a heating surface of 49,248 square feet, which is 14 per cent. more than the Columbia. The motive power is transmitted through three screws, one being placed as in ordinary single-screw ships, and the others being placed on either side, supported by brackets as usual in twin-screw ships. The hull is of steel. The boilers and machinery are well protected with an armour of steel and the guns are well shielded. The main battery consists of one 8in., two 6in., and eight 4in. rapid-firing, breech-loading rifles. The secondary battery consists of twelve six-pounder and four one-pounder rapid-firing guns, four Gatling guns, and five tubes for launching torpedoes. The accommodation for the officers and crew are spacious, well ventilated, lighted by incandescent electric lights and fitted with every possible comfort and convenience. The hull is divided into small water-tight cells or compartments, and there is a double bottom with tanks and cells.

*Water-power projects.*—The utilising of natural water-power for commercial purposes has been carried out very extensively, especially in the Eastern States, where there is ample water supply throughout the year. Many large manufacturing cities, notably Lowell, have large mills and other establishments driven by water-power, and the successful work at Niagara, where one of the largest paper mills in the world is now in operation by the new power plant, has given a great impetus to new projects. Work is now approaching completion for the utilisation of 35,000-horse power of the falls of the Androscoggin River at Rumford Falls, and about 8000-horse power are already being developed by a wood pulp and paper mill turning out 120,000 lb. of paper per twenty-four hours, and by other plants. The river here makes a great loop, with three separate falls in the upper part. The head of the upper canal is above the first falls, and the head of the middle level canal is above the second falls. These canals are practically parallel, the middle level receiving the water from the raceways or weak weirs of the high level. From the middle level the water flows to the low-level canal, which has no head from the river, and this discharges into the river below the third falls. Two dams form slack water for the canal head-gates, and for storing logs for the saw mills. The fall from the high level to the middle level is 100ft., developing 25,000-horse power; from the middle level to the low level it is 50ft., with 12,000-horse power, of which 8000-horse power are already utilised; and from the low level to the river it is 30ft., with 7000-horse power.

*Asphalte deposits.*—A company has been organised to develope the asphaltum deposits in Oklahoma—formerly the Indian Territory—and both liquid asphaltum and bituminous sand will be put on the market. Several shafts have been sunk to depths of 15ft. to 40ft., and the beds are said to consist of a layer of the asphaltic sand overlying a bed of viscid bitumen, which is very sticky and difficult to extract. The chemical analysis of this bitumen is as follows:—

| | |
|---|---|
| Carbon .. .. .. .. .. .. .. .. .. .. | 55·00 per cent. |
| Hydrogen .. .. .. .. .. .. .. .. .. | 10·21 ,, |
| Oxygen .. .. .. .. .. .. .. .. .. .. | 7·14 ,, |
| Nitrogen .. .. .. .. .. .. .. .. .. .. | 2·74 ,, |
| Silicate and ashes .. .. .. .. .. .. .. | 24·91 ,, |

*Sewage irrigation.*—In a recent paper before the California Sanitary Convention, Dr. Orme pointed out the advantage in fertilisation to be obtained by using sewage instead of water only. The excreta of human beings is the most valuable, but owing to its rapid decomposition it must be applied to the soil within two or three days, and the only practicable way is by water carriage. The volume of carrying water must not exceed 50 to 60 gallons daily per capita, or the area of land near a city and available for irrigation would be inadequate. At Los Angeles it is found that the whole sewage can be disposed of in this way, but sanitary rather than financial results must be given first consideration.

*Steel sleepers.*—The use of steel railway ties or sleepers is making but slow progress in this country, and this progress is doubtless made even slower than it might have been by the rapid introduction of steel tie-plates or base-plates to distribute the load over a greater surface than the area of the rail base, and thus prevent the wear and cutting of the wood. A trouble met with on two roads using steel ties has been the necessity for insulating the rails from the ties where a track circuit is used for operating block signals; this involves considerable expense. A street railway is about to experiment with the Daniel's tie, which is a corrugated plate to which the rails are bolted.

## THE IRON, COAL, AND GENERAL TRADES OF BIRMINGHAM, WOLVERHAMPTON, AND OTHER DISTRICTS.

(*From our own Correspondent.*)

The accountants to the Iron Trade Wages Board have this week issued their return of the selling prices of manufactured iron for May and June. The net average of bars, hoops, sheets, and plates of best and common qualities combined is declared as £5 19s. 4·98d. per ton. This compares with £6 0s. 3d. for March and April, and £6 for May and June last year. Ironworkers' wages will remain unaltered at 7s. 6d. per ton for puddling until October 6th next year.

Engineering firms engaged in the manufacture of pumping engines should be acquainted with a unique experience which has just happened to the South Staffordshire Mines Drainage Commissioners in connection with the working of their immense pumping engine plant, owing to the premature rotting of three large pitch pine main rods attached to the new powerful engine at their Moat Pumping Station. The pump came to a sudden stand, and but for the happy possibility which presented itself of starting other engines, serious flooding of the surrounding collieries must have occurred, and great damage been caused. Fortunately, however, only one colliery was flooded, and other rods being in stock it was possible to get the pumps to work again in seven days eleven hours after the accident. The breakdown is attributed to the gases and damp air from the underground levels having prematurely eaten a way into the rods on their return in the up-cast shaft, and rods which should have lasted twenty-seven or twenty-eight years proved under such conditions to have only a lifetime of eight or nine years. The engineer to the Commissioners also points out that large-sized timber is often overgrown, and the turpentine, so necessary to its vitality, is frequently extracted.

An alarming boiler explosion, for the probable cause of which no authoritative theory has yet been advanced, took place on Friday of last week, at the extensive iron and engineering works of Messrs. Cochrane and Co., Woodside, near Dudley. The scene of the occurrence was the bridge-making department, where about 250 men were employed at the time. The boiler, which was situated under an iron shed in a corner of this part of the works, was of the vertical type, being 4ft. 6in. in breadth, and 10ft. high, and was used for supplying power to an iron cutting machine in close proximity to it. The boiler, which, it is stated, was in a good state of repair, having recently been thoroughly overhauled, had only been restarted the previous day, it having been idle for several weeks, and this is the only explosion which has taken place at the works during a history of fifty-four years. Happily, only five men were injured, and the damage done to property was not very great. The boiler was lifted right out of its seating, and the top portion was carried over a high building and landed at a distance of about fifty yards away, while other portions which were mostly torn into small sections, were scattered some of them a distance of 150 yards.

---

[*] Paper read before the Institution of Naval Architects on July 26th, 1894.

With respect to the proposed amalgamation of several Coventry cycle firms, it is stated that the capital will be put down at £180,000, a large proportion of which is to be reserved by the interested firms. The main idea of the projectors of the scheme is to manufacture all the component parts of a cycle, and not send to Birmingham and Wolverhampton for them, as is the case at the present time.

## NOTES FROM LANCASHIRE.

(*From our own Correspondent.*)

*Manchester.*—There is still a very depressing outlook all through as regards the engineering, iron, and coal trades of this district. The continued absence of new work of any weight coming forward is still the general complaint amongst engineers; only in a comparatively few isolated cases are they at all busy, and this chiefly upon special work. In the iron market business drags on much as it has done for a considerable time past, with a persistent weakening tendency in prices, except where they are directly influenced by the miners' strike in Scotland and the cessation of production in that important iron centre, and the only feature in the present position which can give any satisfaction whatever to producers and manufacturers is the fact that stocks are excessively low, so that any slight revival in trade would speedily make itself felt. The prospects in the coal trade are anything but hopeful. Coalowners are endeavouring to hold on to present rates, but the whole tendency of prices is in favour of buyers, who are consequently not anxious about covering forward requirements.

The Manchester iron market on Tuesday was not more than very moderately attended, and both for raw and manufactured material the inquiries coming forward were for the most part only of very small weight. With regard to local and district brands, there is a continued weakening tendency in prices for Lancashire pig iron, and it is scarcely possible to give anything like definite quotations, as local makers are altogether out of this market except at prices considerably under their quoted rates, and beyond occasional small special orders with some of their regular customers they are doing little or nothing. For district brands prices continue extremely low, especially as regards Lincolnshire, whilst Derbyshire tends steadily in a downward direction. For delivery equal to Manchester, Lincolnshire is quoted about 38s. for forge to 39s. for foundry, net cash, but 3d. under these figures is reported to have been taken in some cases, and where buyers have orders to place they are holding back for still lower figures before they are disposed to put through transactions. Derbyshire foundry brands vary considerably; some brands could now be readily bought at 42s. 6d. and 43s., with others quoted about 45s. net cash, delivered Manchester. A generally firm tone is maintained for outside brands offering here, Scotch iron, if anything, tending to harden, owing to the very limited quantities that are obtainable. Delivered equal to Manchester, good foundry brands of Middlesbrough are not obtainable under 43s. 10d., whilst for Scotch iron, which is mostly in merchants' hands, quotations vary according to circumstances, but 45s. 6d. may be given as about the average figure for Eglinton, and Glengarnock may be quoted about 49s. 6d. net prompt cash, delivered at the Lancashire ports.

The finished iron makers report this branch of trade without any improvement whatever. For the most part forges are scarcely going more than three to four days per week, and new business comes forward only in driblets from hand to mouth. Quotations are unchanged, but for favourable specifications makers in some instances might possibly give way a little. For bars the average basis of prices remains about £5 7s. 6d. for Lancashire, and £5 10s. for Staffordshire bars delivered here; Lancashire sheets are still quoted about £6 17s. 6d. to £7 2s. 6d.; and Staffordshire, £7 5s.; Lancashire hoops, £5 17s. 6d. for random and £6 2s. 6d. for special cut lengths, delivered in the Manchester district.

In the steel trade only a very quiet business is still reported, so far as raw material is concerned, with prices about 52s., less 2½, for foundry hematite, and £4 net cash for ordinary basic billets delivered here. Local makers of steel boiler plates have, however, been booking a fair amount of business, owing to Scotch plates being for the present out of the market, and they have been enabled to secure about £6 10s. for delivery in the Manchester district.

The work of completing the equipment of the Manchester and Salford Docks and the dredging of the Manchester Ship Canal over those portions where the full depth has not yet been obtained is being vigorously pushed forward, and it is expected that in the course of a few weeks the waterway will have a depth of 26ft. from end to end. Already vessels drawing over 22ft. are enabled to enter the docks without difficulty, and, as regards traffic, this is showing steady improvement in the weekly tonnage of vessels entering and leaving the port. The engineers in this district are now using the canal much more freely, and amongst recent consignments from the Salford Docks has been the first large Lancashire boiler, Messrs. Joseph Adamson and Co., of Hyde, having shipped one of their boilers 30ft. long by 7ft. 6in. diameter, and weighing about eighteen tons, by the Dynamic, for Belfast. Other engineering firms are also beginning to use the canal for exceptionally heavy machinery, Messrs. Kendall and Gent, amongst others, having shipped by the canal several heavy pieces during the past week, including a large special milling machine, whilst Sir Joseph Whitworth and Co. shipped the other day a steel shaft weighing fifteen tons for the White Star steamer Germanic, in the hands of Harland and Wolff, which for the first time brought the recently erected thirty-ton crane into requisition.

Although there is perhaps not quite so complete a cessation of inquiry in the coal trade as reported last week, the business doing continues only of very limited dimensions, and stocks are rapidly accumulating, with collieries only in exceptional cases working more than three to four days per week. Here and there some giving way has taken place in prices, upon last month's rates, and stocks held at the collieries are beginning to be pushed on the market at rather lower figures, but generally there is no actually quotable change on prices which have been ruling of late, and the leading Manchester colliery concerns, at a meeting held on Tuesday, to consider what action should be taken with regard to prices, decided to follow much the same policy as had been adopted by the Lancashire and Cheshire Coal Sales Association at their meeting last week. The reduction in wages which comes into operation this month has been much more than discounted by the reductions which have already been made in prices, and on these grounds they considered that buyers are in no way justified in asking for any further concession. The leading coalowners are therefore determined to make every effort to maintain present prices, and although in special cases to meet exceptional circumstances which may arise there may be some giving away, the quoted list rates in the Manchester district will remain practically unchanged, at any rate for the present. All descriptions of round coal are hanging upon the market, but the average qualities remain at 11s. to 11s. 6d. for best Wigan Arley, 10s. to 10s. 6d. for Pemberton 4ft. and seconds Arley, 8s. to 8s. 6d. for common house coal, and 7s. to 7s. 6d. for steam and forge coals, although it is exceptional where the maximum figures are being actually got. Engine classes of fuel, which have become a drug upon the market recently, especially as regards the commoner sorts, are rather easier, inferior qualities of slack being readily obtainable at 4s., with good medium qualities about 4s. 9d. to 5s. 3d., and some of the best slacks still quoted at 5s. 9d. to 6s. 3d. per ton at the pit mouth.

Business in the shipping trade is not quite so active as it has been, and for ordinary Lancashire steam coal delivered at the ports on the Mersey not more than about 9s. is now being got.

Athough the settlement arrived at by the Coal Trade Conciliation Board, which is now being practically accepted by both the miners and the coalowners throughout this district, puts an end to any further disruption on the general wage question for the next two years, there are so many extras connected with miners' wages, which vary at different collieries, and are open to modification in some way or another, representing in some cases quite as serious a reduction as the 10 per cent. that has been agreed to, that it can scarcely be said that all trouble in connection with wages questions is at at end. In view of the possibility of numerous isolated disputes arising upon these miners' wages questions, the Lancashire Federated Coalowners and the Lancashire and Cheshire Miners' Federation are endeavouring to form a local Coal Trade Conciliation Board, which can deal with these matters independently of the general Conciliation Board. This local association is in fair way of being established, and it is hoped that it may be the means of preventing any serious disputes arising in the district on isolated questions connected with wages, which might otherwise prove a considerable disturbance to the trade.

*Barrow.*—The hematite pig iron trade of the north-west of England cannot be described in any way but as lifeless, and the new business of the past week has been exceedingly small. Some makers are still engaged on old contracts, but these are being rapidly worked out, while other makers who have practically cleared their books are running iron into stock with no early prospect of realisation. Makers find that at present prices there is no remuneration left in the smelting of pig iron after all costs are paid. The present condition of things points to an early reduction in the make of iron, as it is folly of the worst type to produce more iron than is wanted at a time when prices mean a loss, and when prospects of an improved trade are so remote. Prices of warrants are quoted at 43s. 11½d. sellers, net cash; and buyers, at 43s. 9½d. Makers are still quoting Bessemer iron in mixed Nos. at 44s. 6d. to 45s. 6d. net f.o.b. Stocks have increased during the week, but only to the extent of 194 tons. There is now in stock in warrant stores 155,801 tons, being an increase since the beginning of the year of 61,178 tons.

Iron ore is still a very weak trade, and the continuance of the Scotch strike does not help to improve matters, as there is a smaller consumption of native hematite at Scotch furnaces. Ordinary sorts of iron ore are still quoted at 8s. 6d. per ton net at mines. Lower prices cannot be expected, as raisers in the majority of cases are working their mines at a loss.

Steel makers complain of the scarcity of orders for rails, and from present prospects there is not likely to be any improvement, as there are no big specifications in the market on foreign or colonial account, and this is the source of the trade which is necessary to keep British rail mills employed. There is, however, a good trade in steel plates for shipbuilding purposes, and makers are fairly well sold forward. Other branches of the steel trade are, however, quiet, and orders are held to a small extent only.

Shipbuilders and engineers ara busy, but do not report any new orders.

Coal and coke are in poor demand, and supplies are small, but prices remain unchanged.

The shipping trade is still very much depressed. The exports of pig iron and steel from North-west ports during the past week have amounted to 11,406 tons, against 16,389 tons in the corresponding week of last year, a decrease of 4983 tons. The metal shipments this year so far have been 442,161 tons, comparing with 441,217 tons in the corresponding period of last year, an increase of 954 tons.

## THE SHEFFIELD DISTRICT.

(*From our own Correspondent.*)

THE South Yorkshire coal trade is in a very quiet condition. Although there is no great enthusiasm over the wages arrangement, it is regarded as about the best thing that could be done in the circumstances. It is admitted as an agreement more in the interests of the men than the masters; but the alternative was too serious to entertain. No doubt the coalowners, if they had gone before Lord Shand, would have got a 10 or maybe a 15 per cent. reduction; but there was the certainty of its being demanded back in the winter, with the prospect of a new struggle if refused. The coalowners generally were reluctant to face that risk. The men are gradually falling in with the 10 per cent. reduction; but prices are now so low, that very little profit can possibly be made out of coal this season. The supply is far in excess of the demand. Very little is going to London. Prices are as low as they can be, yet merchants appear to expect still further reductions. Silkstones are now making from 9s. 6d. to 11s. per ton; Barnsley softs, from 8s. 6d. to 10s. per ton; other qualities, from 8s. per ton. Steam coal is in steady request, local collieries, which are fairly well employed, sending large quantities to the Humber ports. Not much is reported doing in other directions, railway companies being the only large customers on account of contracts. Barnsley hards fetch from 7s. 9d. to 8s. 6d. per ton; inferior sorts, from 7s. per ton. Gas coal is at 7s. 6d. to 8s. 6d. per ton. Manufacturing fuel continues in quiet demand, good slacks fetching 4s. 6d. to 5s. 6d. per ton. Smudge and small coal from 2s. per ton; coke in fair request at 9s. to 11s. per ton.

An improvement is reported in the demand for railway wheels, tires, and axles. These are coming in chiefly from India, but there is a considerable call also from the home railway companies. This increased animation in the railway material trade is exceptionally welcome, as goods for the shipbuilding yards are in very light demand, owing to the depression in the marine carrying trade. Several wagon and carriage builders in this district, as well as in Lancashire, report that they are busier than they have been at any time this year.

Much good work is being done by the leading boiler-making firms, the tendency being to put in very large boilers in order to obtain high pressure and thus increase the power of production at a lessened cost. These orders are mainly on account of the home establishments. Rather less is reported in the engineering houses, but one or two firms have some noteworthy special work in hand. Raw material seems to be slightly firmer, not so much as to justify a change in quotations, which for hematites still remain at from 51s. to 52s. 6d. per ton. Common forge iron, 38s.; Bessemer billets, £5 7s. 6d. to £5 10s.; bar iron, £5 10s. to £5 15s.; ordinary iron sheets, £8 10s.; common wire rods, £5 5s.; rope rods, £8 8s.; high carbon rods, £8 8s.

Much local interest is still excited in the fresh development of the battle between projectiles and plates. The makers of armour are not at all doubtful of their ability to produce plates strong enough to resist the new shell, for which we are indebted to Russia. The Russian shell, it is stated, has its chief feature in being fitted with a cap of soft metal to take the first impact of the hardened surface of the opposing plate. This cap, it is said, permits it to penetrate through the armour with very little injury to itself. Local experience has suggested different ways of overcoming the difficulty, and there is no doubt that the armour-plate firms will, as hitherto, be equal to the requirements imposed upon them. The Government, as mentioned last week, have been offered by Messrs. Thomas Firth and Sons specimens for trial of shells made on the Russian principle. So far as is known at present no date has been fixed for these experiments, on which not a little depends. The Admiralty have not thought it needful to make any modification of their armour-plate contracts, which are now being actively proceeded with at the Atlas Works, the Cyclops Works, and the River Don Works. A good deal of war material is also being turned out at present in gun forgings, steel castings, and forgings for the new vessels, and on the whole the various military departments are kept pretty busy on British orders. Any increase in the way of foreign requirements would make our principal firms exceedingly well off for work. One of our large concerns has an important contract for armour for the Government of Japan, but that work is spread over a series of years. Had the military advisers of the Mikado anticipated the rupture with China, no doubt these orders would have been placed at an earlier date for immediate delivery.

There is a fair amount of orders in hand for marine castings and forgings for distant Governments.

Business is rather dull in the heavy steel trades, and were it not for our own Admiralty work many of the hands employed in the East End would be on short time. The dividends declared for the year ending June 30th, by the principal companies engaged in the steel and gannister trades, are invariably weaker than for the corresponding period of last year. Makers of gannister and similar fire-resisting appliances have been seriously affected by the double strike in the north and south. Where there is no work in the iron and steel furnaces, there is, of course, no call for fire-resisting linings, which form the chief specialities of these establishments.

Manufacturers of edge tools are still very well off for work, and most of the best houses are under considerable pressure to make deliveries. Files are again in better request, some very important lines having been received on Russian and German account. Agricultural and gardening tools, after a brief period of depression, are again being freely inquired after.

There is no improvement to note in the cutlery and electro-plating trades. It was expected that there would be an end by this time of the suspense created by the American tariff question. In the absence of anything definite from the United States, firms with an American connection report that business goes from bad to worse. It is freely reported that there never was a time when the cutlery output in Sheffield was so small. High-class goods, for presentation and similar purposes, elegantly done up in handsome cases, are still well inquired after for the States. These grades are not much affected by tariffs, as the American will have the best English goods for such purposes. There is an idea that although the passing of the Wilson Bill may give a stimulus to the Sheffield cutlery craft, it will not be of long duration. A great feature of the Sheffield trade with that market has been table knives. Of late years this has been getting less and less, and the expectation is that it will gradually decrease till it reaches very unimportant dimensions. The Americans, however, have not made so much progress in fine pocket cutlery, and our local houses anticipate an active call for that class of goods in the fall of this year. As regards silver and electro-plate, there has rarely been a time when so little work was doing; indeed, several firms have withdrawn their travellers for a time on account of their journeys having turned out so unremunerative. The price of silver seems now to have settled at about 2s. 4½d. per ounce, fluctuating now and again a little above or a little below that figure.

Ivory cutters are complaining severely of the inaction in their line, caused by the decline of the cutlery and silver trades. Many of them have a large amount of capital lying idle in their accumulated stocks of hafts. The stag horn cutters are rather better fixed, as the use of tips for umbrellas and walking sticks has now become an important factor in their business. The London ivory sales, held last week, seem to point to the conclusion that ivory will not get any lower in some qualities. Better rates were realised and a large business was done.

The Lord Provost of Edinburgh, the Right Hon. Sir James Russell, LL.D., paid a visit to the works of Messrs. Charles Cammell and Co. last week. There his lordship witnessed the rolling of an armour-plate weighing 26 tons. This is intended for the citadel of the new warship Magnificent. The plate was reduced from a thickness of 14½in. to 9in. under the huge rolls. Subsequently the Harvey process of hardening armour-plate was explained. At the works of Messrs. Thomas Firth and Sons, the Lord Provost witnessed the process of manufacturing projectiles. His visit was at an interesting period, when a fresh development of the contest between armour and shell is in progress. Sir James Russell afterwards visited the manufactory of Messrs. Mappin and Webb, where the production of silver and electro-plated goods was explained by Mr. H. Howlden, the general manager, whose guest his lordship was during his visit to the town. The Lord Provost expressed himself as much interested in the magnitude of the works carried on in the large East End establishments, and in the beauty of the process associated with the silver trade.

Messrs. Newton, Chambers, and Co., of the Thorncliffe Ironworks, were awarded a silver medal for their stable fittings at the Royal Lancashire Show, held at Bolton, where they had a representative exhibit.

## THE NORTH OF ENGLAND.

(*From our own Correspondent.*)

THE depression in trade is increasing, and in no department of the iron and allied industries are manufacturers doing even a fairly satisfactory business. Most people agree that a worse time has not been experienced since 1879, and some hold that a more trying time has never been seen during the present generation. And yet in the early part of the year there was every prospect of a revival, but unfortunately strikes have come in and killed the improvement. The strike that has had the most to do in bringing about this result has been that of the moulders, which has now lasted five months, and appears no nearer the end than it did weeks ago. Practically nothing has been done during the past week towards ending the struggle, and the already widespread distress is every day being extended as works are compelled to close, because manufacturers cannot procure the castings which they need. It will scarcely be believed that because 1500 moulders refuse to work, nearly 18,000 other workmen, engaged in iron and steel works, engineering works, shipyards, &c., have to be compulsorily retired from their labours, and many of them are practically starving, yet they have no voice in the settlement of the dispute. The engineers did come out on strike for an advance of wages similar to that demanded by the moulders, but recognising after a time that trade had fallen back, and did not justify their persisting in the demand, they withdrew their claim; but that has not availed them anything, for as long as the moulders keep out there can be no work for the engineers. It certainly is high time that in the interests of the thousands who are unwillingly thrown out of work by the strike, greater efforts should be made to bring the contending parties to an agreement. It is a most serious matter for the iron and shipbuilding industries to have to suffer from this enforced idleness. Messrs. Richardson, Duck, and Co., and Messrs. Craig, Tayler, and Co., both shipbuilders at Thornaby-on-Tees, have had to close their yards, and now out of eight yards on the Tees only one is in operation, and that is a small one. At the Hartlepools there is only one at work, and on the Tyne and Wear a large proportion of the shipyards and engine works are idle. On this account it is impossible to keep the iron and steel works in anything like full operation, and some have had to be closed altogether. Messrs. Dorman, Long, and Co. are stopping their West Marsh and Britannia Works at Middlesbrough, and Messrs. William Shaw and Co. have this week closed their Wellington Cast Steel Foundry, Middlesbrough. Messrs. Dorman, Long, and Co. have orders booked, but while the shipyards are closed cannot get the specifications; and as to their girder business, it is said that the stocks at their depôts are so large that a stoppage for a time will involve no inconvenience. The works of the Darlington Steel and Iron Company are to be closed after the orders now on the books are completed and the stock of materials used up, which will be in about three weeks. The works are to stop for an indefinite period, and 800 men will be thrown out of employment. In this case, however, it is not the moulders' strike that can be blamed for the stoppage, because the Darlington Company do not produce plates or angles, they confine their attention mainly to rails, and it is the general depression of trade that is affecting them. The chairman of the company addressing the shareholders on Monday, at the half-yearly meeting, said that such a condition of trade as the present had never been experienced since he entered commercial life, and one would have to go back sixty or seventy years to find anything as bad. He remarked that, during the twelve years since he was appointed chairman, the company had manufactured 750,000 tons of steel, for which they had received about £4,000,000, and the total amount of profit on that was £74,164, of which the shareholders got £43,000, or 3d. out of every £1 received. The ordinary shareholders got dividends in only four out of the twelve years. The loss incurred in the last financial year ending April 30th was £3571, and since then the loss had been going on, and the difficulties under which they laboured had been increased. Under the circumstances the directors thought it best to close. Darlington has not an equal chance in competing with other works nearer the seaboard for rail orders, because most of the rails now required are for export, and being an inland place and away from a navigable river, extra cost is incurred in shipping the rails.

The slackening of operations at most of the steel works, and the closing of others, has lessened the demand for hematite pig iron, and the trade in that is extremely dull, while prices are drooping, because while consumption has decreased the production has not been curtailed, and stocks are increasing, though the stock in Connal's stores last month shows a decrease of 272 tons, the quantity of hematite held at July 31st being 43,317 tons. Makers are not reducing their output, because they are not averse to augmenting their stocks, which are only small; indeed, a short time ago they had in some cases difficulty in supplying all that was required. They are now desirous of accumulating a stock to meet the autumn business, and thus none of the furnaces are put out. The quotation now for mixed nos. of East Coast hematite pig is 43s., but there have been sales this week at 42s. 9d., and even 42s. 6d. A good deal of hematite pig iron has been sent to Russia and Italy during the past month.

Cleveland pig iron is also produced in excess of requirements, for though exports have of late been good, yet much less is consumed locally. Since last report, No. 3 Cleveland G.M.B. pig has been sold at 35s. 4½d., and in a few cases at 35s. 3d., for prompt f.o.b. delivery; but sellers are again asking and realising 35s. 6d. and will not take less, as that has been the price of warrants. The stock of Cleveland pig iron in Connal's warrant stores at July 31st was 95,392 tons; decrease, 2639 tons for the month. No. 1 Cleveland pig iron is quoted 37s. 6d.; No. 4 foundry, 34s. 6d.; and grey forge, 34s. The increase in stock is mainly in the commoner qualities of pig iron.

The pig iron shipments from Middlesbrough — including Skinningrove—during July reached 88,329 tons, the exports to foreign parts being the best that have been reported since last October, but to Scotland there has been a considerable falling off. The following is a summary of the shipments as compared with the previous months named:—

| | Coastwise tons. | Foreign tons. | Total tons. |
|---|---|---|---|
| July, 1894 .. .. .. .. | 35,551 .. | 52,778 .. | 88,329 |
| June, 1894 .. .. .. .. | 43,335 .. | 46,515 .. | 89,850 |
| May, 1894 .. .. .. .. | 44,514 .. | 47,420 .. | 91,934 |
| July, 1893 .. .. .. .. | 25,294 .. | 54,957 .. | 80,251 |
| July, 1892 .. .. .. .. | 11,741 .. | 30,188 .. | 41,929 |

Germany last month received 24,000 tons of pig iron from the Tees, Russia 10,543 tons, and Italy 6195 tons, that to the last two countries being chiefly hematite iron. Altogether, 582,742 tons of pig iron have been shipped this year, against 549,732 tons in 1893, and this year's quantity is the largest ever known. Germany has had over 120,000 tons, or more than a fifth of the total shipment, and Scotland 246,791 tons, or two-fifths.

The finished iron and steel trades are extremely slack, and prospects are discouraging, but no further reductions in prices are made, because quotations are now at figures which leave no margin for profit. Mr. Waterhouse has submitted to the Board of Conciliation his statistics of the quantities of and average prices realised for manufactured iron in the North of England during May and June, 1894. The average price is practically the same as in the previous two months, viz., £4 17s. 8·30d. or 0·03d. less. In accordance with the sliding scale, wages of finished ironworkers during August and September will be at the same rates as they have been in June and July. The deliveries fell off about 2600 tons, chiefly, as might be expected, in plates.

The half-yearly meeting of the Board of Conciliation and Arbitration for the Manufactured Iron and Steel Trades of the North of England was held on Monday. This organisation is now twenty-five years old, having been founded in 1869. The president had a very good account to give of its work during the past half-year. This board has been the model for many similar institutions founded, not only in this country, but also on the Continent and in America. An effort is being made to shorten the hours of work at mills and forges, particularly on the Saturdays.

The Consett Iron Company's directors report that their profits during the last financial year reached £124,786.

Alderman Philip A. Berkley, who has for many years been connected with Palmer's Shipbuilding and Iron Co., has resigned his position, and retires into private life.

There is nothing new in the coal trade, and business on the whole is much better than might be expected, taking the stoppages of so many works into account; but the decrease in consumption locally is more than counterbalanced by extra deliveries to Scotland and also to the Continent, and very few of the collieries lose any time. The annual meeting of the North of England Institution of Mining and Mechanical Engineers will be held at Newcastle on Saturday.

In connection with the jubilee of the firm of Bell Brothers, the employers set aside £500 to be spent in entertaining the men at their different works—at Clarence Blast Furnaces on the Tees, at their collieries at Fursdale, Browney, and Page Bank, in Durham, and at their mines and quarries in Cleveland and Weardale last Saturday. The men at these places number over 10,000.

## NOTES FROM SCOTLAND.

(*From our own Correspondent.*)

THE Glasgow pig iron market continues very quiet, business being greatly hampered by the colliers' strike. Scotch warrants have sold in small quantities at former prices. There has been little doing in Cleveland warrants, and hematite iron is quite neglected.

The prices of makers' special brands are steady as follow:— G.M.B. f.o.b. at Glasgow No. 1 is quoted 43s. 6d. per ton; No. 3, 42s. 6d.; Monkland No. 1, 47s.; No. 3, 42s. 6d.; Carnbroe No. 1, 47s.; No. 3, 46s.; Clyde No. 1, 55s.; No. 3, 49s.; Gartsherrie No. 3, 49s.; Calder and Summerlee No. 1, 56s.; No. 3, 49s.; Coltness No. 1, 57s.; No. 3, 41s.; Glengarnock at Ardrossan No. 1, 52s. 6d.; No. 3, 49s; Eglinton No. 1, 51s.; No. 3, 46s.; Dalmellington at Ayr No. 1, 50s.; No. 3, 46s.; Shotts at Leith No. 1, 55s; No. 3, 51s. 6d.

The shipments of pig iron from Scottish ports in the past week amounted to 2807, compared with 6502 in the corresponding week of last year. Of the total there was sent to South America 75 tons, India 20, Australia 360, France 35, Italy 850, Holland 40, Belgium 80, Spain and Portugal 100, China and Japan 200, other countries 265, and coastwise 782, compared with 3747 in the corresponding week.

There is no change in the number of furnaces in blast, which is 11, compared with 62 at this time last yeat. Ordinary iron is being produced at Coltness by 3 furnaces, and at Shotts by 4, while there are 4 furnaces making basic at Glengarnock.

As regards the market for finished iron and steel, the amount of business is inconsiderable; very few of the works have yet resumed, being deterred by the apprehension of dear coals. Conferences have taken place in one or two districts between employers and workmen with the object of endeavouring to arrange terms on which work could be started. A proposal has been submitted to the men to the effect that while the strike lasts they should allow one-half of the extra cost of coal to be deducted from their wages.

The iron and steel manufactured goods shipped from Glasgow embraced locomotives worth £3170, sewing machines £915, other machinery £13,128, steel goods £6153, miscellaneous iron goods £23,034.

The coal trade is almost dormant, owing to the continuance of the strike. Stocks, which were held mostly in Fifeshire, are now reported to be well exhausted. Consumers have been keeping out of the market as much as possible, so as to avoid a rise in prices. Numerous vessels, for the most part small in size, have arrived in Glasgow and other ports from England with cargoes of coal. The price at the ship's side in Glasgow harbour is so far moderate in the circumstances, being from 9s. to 10s. per ton. The exports of coal from Scottish ports during the week reached only 24,246 tons, compared with 140,864 in the corresponding week.

The strike has now lasted about five weeks, and during that time only two small distributions of money have been made to the men. Much distress is reported in the mining districts. Efforts have been made to bring about a settlement of the dispute, but these have proceeded on the assumption that the employers may possibly agree to some concessions to the men; and as there is nothing in the state of trade to warrant an increase of the cost of production, there is no chance of effecting a settlement on any such basis.

## WALES AND ADJOINING COUNTIES.

(*From our own Correspondent.*)

THE usual and natural sequence to colliery explosions—the inquest and verdict—have taken place in respect of the Albion; and, from the Home Secretary to the colliery officials, there is subject matter for reflection in the verdict now rendered. This was as follows:—"The jury found that the deceased had lost their lives through an explosion at the Albion Colliery, on June 23rd, 1894, which explosion was accelerated and extended by coal dust; but the jury disagree as to the exact place at which the explosion had its origin, and we are unanimously of opinion that shot firing was practised in the colliery when the men were at work, without sufficient precautions as to their safety, and contrary to rules; we are also of opinion that the under-manager neglected his duty in not seeing that his subordinates in the night shifts performed their duties in accordance with rules; that the firemen were negligent in not reporting gas when found, and that there is not a proper system of watering in the mine. The jury beg to make the following recommendations:—(1) That shot-firing in timber shall be absolutely prohibited; (2) that all old workings shall be properly shored or gobbed; (3) that a record shall be kept of the number of men in the mine at all hours; (4) that thorough inspection shall be more frequently made by her Majesty's inspectors, because we consider the present examinations by the workmen's representatives worthless." With this verdict the Albion is relegated to the long list of fatalities, and in the meanwhile, before the next calamity, there is no doubt a good deal of useful work will be done in the way of prevention. There is, however, a significant hint in the fourth clause—"the examination by the men's representatives is worthless." If it be true that the very men who are more interested than any others in avoiding accidents are not to be trusted, there is little security against a recurrence in one pit or another. Steam collieries are recruited from all quarters—Cornish tin workers, North Walian lead workers, labourers from all parts. Then we have the "rush" to get out as much coal as possible, a colliery never suffered to get cool, and any day an explosion. The recommendation for more inspection is a good one. Inspections outside the coalowners' jurisdiction are needed, and, to be of practical service, they should be quadrupled at least in number.

On Saturday the Sliding Scale Committee held their audit meeting at Cardiff, when the results of the examination of coalowners' books showed the justification for a reduction of wages to the extent of 3¾ per cent. The last reduction, in April, was 2½. This now leaves wages at 23¾ per cent. above the standard. In all probability the next audit will declare an advance, as the demand for coal has been well sustained of late, and prices have been fairly high and firm. Last week again the total coal shipment from the Cardiff ports exceeded 300,000 tons, and this week's total I expect will be larger, as the monthly holiday that is looming generally incites to greater effort in the preceding week.

Some little unpleasantness has arisen again amongst the collieries. It would seem as if explosions underground must be followed by ruptures above. The question now under discussion is the objection of the coalowners' committee to take checkweighers' evidence. A good deal more is made of it than is justified, and, as usual, representatives of the Miners' General Federation are trying to widen the breach.

The coal outlook continues very satisfactory, and marked activity continues in all directions.

The last new and successful colliery undertaking, the Llanbradach, was the scene of a pleasant gathering last week. The directors and many of the largest shareholders met to see the first output of No. 2 pit, and having noted the landing of several trucks, sat down to a luncheon in celebration of the starting of, in all probability, a long and prosperous annal. Both pits are now working well, and a township is arising, which is certain to be a large and prosperous one. The strong likelihood is that in a few years, at least, a place equal in size and importance to Mountain Ash, will stand where only a few years past there was not even a cottage.

It is to be hoped that local authorities will keep pace in providing all necessary places and institutions for the new community. Not unfrequently this is omitted, and an isolated township is handicapped badly.

The coal market mid-week at Cardiff was not so active as one would wish, but there is not much reason for complaint, as prices did not show more fluctuation than about 3d. in best qualities. The latest steam coal prices are:—Best steam, 12s. to 12s. 3d.; seconds, 11s. 6d. to 11s. 9d.; dry coal from 10s. to 10s. 3d. Small steam is accumulating, and cheaper, ordinary kinds are selling at 5s. 3d. to 5s. 6d.; best, 5s. 9d., f.o.b.

In house coal there is no denial a slight weakness has begun to show itself, and appearances suggest that the usual summer quiet season is at hand. One comfort for coalowners is, that it has been so long delayed that it can only be a short one. Best household is selling rather tardily at 11s.; No. 3 Rhondda, 10s. 9d.; brush, 8s. 9d.; small, 6s. 9d.; No. 2 Rhondda, 9s. 6d. and 10s.; small, 5s.

Swansea is busy in coal exports, and last week despatched 36,670 tons; while the vigour of the patent fuel made was demonstrated by an export of 12,208 tons. The coal totals included 14,030 tons to France; San Francisco, 2500; Montreal, 2100, and the United States 1602 tons. Newport continues to display a good deal of activity. Output of the district is large and increasing, and shipments, foreign and coastwise, very satisfactory.

There is scarcely any change in the condition of the iron and steel trades. In rails, small parcels continue to be the characteristic. One went from Newport this week to Clevedon 60 tons. Good and large foreign orders are much needed. In bars an average make is recorded, but prices lack firmness, and on 'Change, Cardiff, this week, as well as Swansea, rails and bars were 2s. 6d. per ton weaker. The lowest quotations, Swansea, mid-week, were as follows:—Welsh bars, £5; sheet iron, £5 15s. to £6 10s. at works; steel sheet, £6 to £6 5s., with the usual extras for higher gauges; Bessemer steel bars, £4 to £4 2s. 6d.; Siemens, £4 2s. 6d. to £4 5s.

In pig iron there is no change. There was an expectation that the Scotch strike would have sent prices up. This has not been the case, and the remark on 'Change was that everything in respect of Glasgow warrants was at a standstill; latest prices are 42s. cash buyers; Middlesbrough, No. 3, 35s. 5d. and 35s. 6d.; hematites, 43s. 8d. for mixed nos.; block tin is at £65 15s. to £66. Iron ore is coming in freely from Cyfarthfa, Dowlais, Blaenavon, and Ebbw Vale. A good deal has also come in to Port Talbot. Swansea prices are: Tafna, 11s.; Rubio, 11s. 3d. Cardiff prices for pit-wood, 15s. 3d.; moderate demand; coke, improving; furnace, 15s. to 16s.; foundry, 17s. to 17s. 6d.; best foundry, 20s. to 21s.

Tin-plate reports are unfavourable, both in respect of the attitude of the men and the state of the market. The uncertainty still prevailing in respect of the American tariff has had a depressing influence on business, and prices are weaker.

The comment on 'Change, Swansea, this week was to the effect that prices continue below any possible profit, and every effort is being made by the men to increase the cost of production, which must in the end come upon the consumer.

There are several important works at present which may any day be declared closed. In fact, rumours have been busily in circulation this week to the effect that a decision to close had been arrived at, but until the actual stoppage I shall not give currency to the statement. The latest quotations are:—Bessemer, 10s. 3d. to 10s. 4½d.; Siemens, 10s. 4½d. to 10s. 7½d.; best charcoal, 11s. 6d. to 12s. 6d.; wasters, 6d. to 1s. less than primes. Ternes remain at 19s. to 23s.

At Briton Ferry the shipment of coal has been marked, especially by Perch and Co.

Large arrivals of iron ore have come from Spain. Briton Ferry blast furnaces are well employed, and production of bars and plates a good average. It is thought that the Earlswood Tin-plate Works will resume operations shortly.

Swansea shipment of tin-plates last week was only 47,079 boxes, receipts from works 64,580 boxes. Stocks now are 307,098 boxes.

Swansea imported last week 1614 tons pig, 205 scrap iron, 233 tin-plates, 598 tin bar, and 2000 tons iron ore.

## NOTES FROM GERMANY.

(*From our own Correspondent.*)

THE situation of the iron and steel trade in this country does not show much change on the week, demand being limited, and prices fluctuating. Here and there a better feeling has been noticeable lately, and makers are, as a rule, less despondent than during previous months, but there is still very much left to be desired, both as regards home and foreign demand, and the prices generally quoted leave no profit.

In Silesia the blast furnace works have been reported in somewhat better employment lately, which may be accounted for by the increasing activity in the malleable iron department, where orders have been coming in quite regularly during the past week; especially bars and sheets are meeting with a healthy demand. There is likewise much animation to be noticed at the tube mills, and prices are firm, if not rising. A very lively business continues to be done on the Austro-Hungarian iron market, all sorts of pig iron being well inquired for. Makers of manufactured iron also report themselves pretty actively engaged generally, although for some sorts rather a decrease in demand has been perceptible, which is chiefly caused by the keenness of German competition. The rail works unfortunately continue insufficiently occupied, and there is now but little hope that orders of any weight will be given out this year. In structural material there is not much doing just now, but autumn demand is likely to be fairly good. The business in hardware has, on the whole, decreased.

The condition of the French iron industry continues quiet but rather satisfactory, pig iron being in fair request at tolerably firm quotations. The greater part of the malleable iron works are regularly employed, and there has been a stiffening tendency noticed with regard to prices. For the present, merchant bars are paid with 155f., girders 165f., p.t. free Paris.

On the Belgian iron market demand and sale continue limited, but prices show a little more firmness. Hitherto the Belgian State Railways have been able to purchase their requirements at extremely low rates, because the Belgian works keenly competed with each other, but now the Belgian steel works have joined in a sort of convention for the purpose of fixing the prices and dividing the orders among the different works. The State Railway administrations have, in consequence of this, been compelled to pay considerably higher prices at a late tendering for rails and appurtenances. During the first two quarters of 1894 the production of the Belgian blast furnace works has been, in pig iron, 189,220 t., against 211,676 t. for the same period last year; foundry pig, 47,415 t., against 39,890 t.; and steel, 207,150 t., against 127,625 t.; totals being 443,785 t., against 379,115 t. last year.

There is nothing new to report concerning the state of the iron industry in Rheinland Westphalia, pig iron being in quiet but pretty regular demand. In the Siegerland there has been a specially good inquiry coming in for spiegleisen, and basic has also been briskly called for in some instances, Belgian demand for that sort having increased of late.

The general position of the finished iron trades shows no improvement, but if anything the outlook is more favourable than in former weeks, bars having met with a fairly active inquiry. Prices, too, have been rather well maintained, makers in most instances refusing to sell at the famine prices which they had been forced to accept when business was at its worst. Girders as well as all sorts of structural iron are in quiet demand, and there is much under-quoting practised; producers, however, show some little inclination to give way in their prices. In the hoop trade inquiries for the fourth quarter have increased, and the mills are vigorously engaged.

There is but an irregular activity reported at the plate and sheet mills, some being well employed, while others are scarcely kept going, but they all unite in complaints regarding the condition of prices. Drawn wire, as well as wire nails, are in poor request on home account, while export business is tolerably good; indeed, there has been a steady increase noticeable in the export of wire nails for the last years. In 1880, for instance, 164 t. were exported, while in the year following export rose on 217 t., in 1882 it was 238 t.; in 1883, 282 t.; in 1884, 386 t.; in 1885, 387 t.; in 1886, 396 t.; in 1887, 413 t.; in 1888, 487 t.; in 1889, 464 t.; in 1890, 410 t.; in 1891, 497 t.; in 1892, 502 t., and in 1893 it was 548 t. Chief consumers for German wire nails are England and Japan, having bought about one-half of the total production last year. Foundries and machine shops are tolerably well employed, and so are the wagon factories generally.

The production of pig iron in the Saar and Mosel district has been, for June, 1894: 23,379 t. forge pig, 53,969 t. basic foundry pig 12,035 t.; together, 89,383 t. Output was 1 per cent. less than during the preceding month of May, when it was 90,268 t. In June, 1893, total production amounted to 84,108 t., showing an increase of 6·3 per cent. for the same month this year. From January to June of present year 533,083 t. were produced, against 498,912 t. for the corresponding period last year. Output during the second quarter of present year was 34,171 t. or 6·8 per cent. more than during the same period in the preceding year.

## AMERICAN NOTES.

(*From our own Correspondent.*)

NEW YORK, July 26th, 1894.

ALL reports from the interior show continued sluggishness. The banks are unable to find borrowers, and the railway managers report traffic poor. Iron and steel makers are doing one half what they usually do, although Pittsburgh and Western Pennsylvania are favoured more than any other locality. The coke strike continues, and a good many concerns are not getting the amount of coke contracted for. In Central Pennsylania 7000 miners are still out. There is an unsettled feeling in all industrial centres, growing in part out of the railroad strike. The western railway managers are succeeding in moving considerable freight. The opinion in manufacturing circles is that the country is on the eve of a general improvement. The country never before experienced such a severe restriction and with so little inconvenience. It has been worth all it cost. Material for construction purposes is offered this week for delivering any time during 1894 on the basis of quoted prices to-day. Large consumers are now seriously considering this proposition, and large orders may soon be made out.

## LAUNCHES AND TRIAL TRIPS.

On the 17th ult., the Montrose Shipbuilding and Engineering Co., Montrose, launched two barges, the New Orleans and St. Louis, 76ft. 2in. long, with 21ft. 5in. beam, and 7ft. 6in. depth, and on the 25th and 26th ult. the barge Uranus, and a sister barge—unnamed—the latter making the fifth barge supplied for London owners.

On Wednesday afternoon there was launched from the east yard of Messrs. C. S. Swan and Hunter, shipbuilders, Wallsend, a steel screw steamer to carry about 5200 tons deadweight of the following dimensions:—Length over all, 340ft. 6in.; breadth, 43ft.; depth moulded, 28ft. 11in. The vessel will be to Lloyd's highest class, and has been built under special survey to the order of Messrs. Burrell and Son, of Glasgow; is of the spar deck type, with poop, long bridge house amidships and forecastle. She will be engined by the Wallsend Slipway and Engineering Company, the sizes of the cylinders being 24in., 40in. and 64in., by 45in. stroke.

On Wednesday morning the s.s. Leyden left the Cleveland dockyard of Sir Raylton Dixon and Co., Middlesbrough, for her official trial trip. She is a steel screw cargo steamer of the three-decked type to Lloyds' highest class, and has been built to the order of Messrs. Robert Alexander and Co., of Liverpool, for the Stoomvaart Maatschappy Leyden, of Rotterdam, the principal dimensions being:—Length, 357ft. 6in.; beam, 43ft. 6in.; depth, moulded, 28ft. The upper and main decks are of steel, the poop, bridge, and forecastle decks of pine, and the vessel will carry about 5400 tons deadweight on a moderate draught of water. The deck machinery for loading and discharging cargoes is very complete, and includes five large steam winches, whilst the hatchways are extra wide and long for carrying boilers and large pieces of machinery, &c. Water ballast is carried in the cellular double bottom, which extends right fore and aft, and the vessel is subdivided by six transverse watertight bulkheads. The engines have been fitted by Messrs. Thomas Richardson and Sons, of Hartlepool, the cylinders being 24½in., 39in., 67in., by 45in. stroke, with two double-ended boilers working at a pressure of 180 lb. per square inch. The construction of the vessel and machinery has been carried out under the supervision of Mr. H. H. West and Mr. S. S. Goodwin respectively, of Liverpool, and Captain M. H. Foster has personally superintended the work.

## SPECIFIC HEATS OF GASES AT CONSTANT VOLUME.

At a recent meeting of the Royal Society a paper was read "On the Specific Heats of Gases at Constant Volume, Part II., Carbon Dioxide," by Dr. J. Joly, F.R.S. In the former experiments on this gas, recorded in the first part of this research,* the highest absolute density at which the specific heat was determined was 0·0378. In the present observations the determinations of specific heat have been carried to densities at which the substance was partly in the liquid state at the lower limit of temperature of the experiments. Observations dealing with true specific heat, uncomplicated by the presence of thermal effects due to the presence of liquid, are limited by the density 0·1444. At this density the mean specific heat over the range, 12 deg. C. to 100 deg. C., is 0·2035.

These observations, combined with those contained in Part I. (*loc. cit.*), afford a well-defined line, which rises slowly at the higher densities, turning away from the axis of density.

According to an empirical equation to this line, the specific heat of carbon dioxide at constant volume is given in terms of its variation with density $\rho$, as follows:—

$$Cv = 0{\cdot}1650 + 0{\cdot}2125\rho + 0{\cdot}3400\rho^2.$$

"On the Specific Heats of Gases at Constant Volume, Part III., the Specific Heat of Carbon Dioxide as a Function of Temperature," by Dr. J. Joly, F.R.S.

In order to investigate the question of the variation of the specific heat of carbon dioxide with temperature, a steam calorimeter was constructed having double walls of thin brass, between which the vapour of a liquid boiling under atmospheric pressure could be circulated. The vessels used in the experiments were hung in the closed inner chamber. Into this chamber steam could be admitted after the temperature had become stationary and the same as that of the jacketing vapour. In this way the initial temperature could be varied.

Experiments at various densities and over four intervals of temperature were carried out. The densities chosen were 0·0456, 0·0800, 0·1240, 0·1800, and 0·1973. The intervals of temperature over which the gas at each density was investigated were: Air temperature to 100 deg.; 35 deg. C., boiling point of ether, to 100 deg.; 56 deg., boiling point of acetone, to 100 deg.; and 78 deg., boiling point of ethyl alcohol, to 100 deg.

The results are plotted on five equi-density lines, in which the precipitation due to the calorific capacity of the gas between $t_1$ and 100 deg. is plotted against the initial temperature $t_1$ in each case. If the specific heat is invariable, these are right lines. This proves to be sensibly the case for the lines $\rho = 0{\cdot}0456$ and $\rho = 0{\cdot}0800$, those of lowest density.

The next line, 0·0124, is nearly rectilinear over the higher ranges, but, pursued in the direction of decreasing temperature, it rises markedly, thus indicating that the specific heat at constant volume falls in value with increasing temperature. The line $\rho = 0{\cdot}1800$, and the one close above it, $\rho = 0{\cdot}1973$, show this variation very markedly. Their variation below the critical temperature is complicated by the presence of liquid.

The following empirical equation expresses the line $\rho = 0{\cdot}124$ calculated into a line of variation of specific heat with temperature:—

$$Cv = a\,(100-t) + b\,(100-t)^2 + c\,(100-t)^3,$$

where $t$ is the initial temperature of the experiment in Centigrade degrees:—

$$a = 0{\cdot}19020000,$$
$$b = -0{\cdot}00006750,$$
$$c = 0{\cdot}00000182.$$

13,994. Capstans or Winches W. Elliot and W. Garrood, London.
13,995. Electric Railways, W. P. Thompson.—(*J. F. McLaughlin, United States*)
13,996. Apparatus for Aerostation, W. P. Thompson.—(*R. de Palacios and W. Goetjes, Germany.*)
13,997. Mud-guards for Cycles, W. Bransom, London.
13,998. Collar Studs, Solitaires, &c., T. R. Thomas, London.
13,999. Apparatus for Making Ice Creams, H. Lane and J. Pullman, London.
14,000. Machinery for Colour Printing, C. A. Beeby, London.
14,001. Ensuring Safety on Single Lines, E. Tyer, London.
14,002. Gas Motor Cars, H. P. Holt, London.
14,003. Feed Troughs, J. G. Davis, London.
14,004. Decorative Window Screen, J. Barrett, London.
14,005. Washing or Mixing Apparatus, A. L. Gelinek, London.
14,006. Manufacture of Glass, G. Bamberg, London.
14,007. Ventilator for Railway Carriages, L. B. Peters, London.
14,008. Railway Chairs, C. Chenu, London.
14,009. Pedals for Cycles, L. Barrow, London.
14,010. Revolvers, L. Nagant, London.
14,011. Obtaining Infusions of Hops, E. Weymar, London.
14,012. Tanning, J. Y. Johnson.—(*F. Kornacher and the firm of Diesel and Weise, Germany.*)
14 013. Cutting or Threading Screws, H. Luckman, Birmingham.
14,014. Condensing Towers, E. J. Barbier, London.
14,015. Treatment of Potable Waters, H. J. N. Bergé, London.

*21st July*, 1894.

14,016. Hub for Wheels of Cycles, S. Johnson, London.
14,017. Working Corking Machines, E. W. Jenkins, Swansea.
14,018. Imitation Stained Glass, J. F. Russell, London.
14,019. Convertible Mail Carts, T. F. Simmons, London.
14,020. Boilers for Consuming Smoke, J. Bloor and A. Welburn, Birmingham.
14,021. Appliances for Measuring Cloth, T. Crowther, Bradford.
14,022. Receptacles for Carbonated Beverages, T. and D. Rylands, London.
14,023. Fire-extinguishers, D. Laffan, Dublin.
14,024. An Improved Candlestick, L. E. Mannings, Bristol.
14,025. Eye-glass Frames, E. Brown and S. Brown, Birmingham.
14,026. A Combined Horseshoe and Pad, J. Money, Renfrew.
14,027. Window Sash Fasteners, H. A Dawson, Lancashire.
14 028. Accelerating the Speed of Steamships, D. Doyle, Cork.
14,029. Prepayment Mechanism Application to Gas, S. Simpson, Mansfield.
14,030. Winding Yarns, C. W. Hollis and Claringburn and Co., Nottingham.
14,031. Manufacture of Socks, A. L. Woodward, Nottingham.
14,032. Hat and Cap Attachments, W. M. Harris, Birmingham.
14,033. Envelope for Book Packets, A. Guye, Surrey.
14,034. Device for Taking Personal Measurements, W. P. Thompson.—(*E. von Lange, Germany*)
14,035. Bicycle Sulkies, F. S. Stoddard and J. Nottingham, Liverpool.
14,336. Manufacture of Wool, T. Seddon and C. Long, London.
14,037. An Improved Toy, R Field, Huddersfield.
14,038. Bicycles and other Velocipedes, G. Pinnington, Chester.
14,039. Bodkins, A. W. Summers, Manchester.
14,040. Fastening for Trousers, H. Goldman, Manchester.
14,041. Storage Box for Photographic Negatives, J. B. Brooks, Birmingham.
14,042. Lamps, G. Wooliscroft and H. Garland, Cheshire.
14,043. Device for Securing Ladies' Hats, H. Sampson, Uxbridge.
14,044. Torpedoes, R. Parry, Holyhead.
14,045. Reducing the Resistance of the Water on the Hulls of Vessels, T. Blackett, Newcastle-on Tyne.
14,046. Shaft Bearings, G. V. Maxted and F. Knott, London.
14,047. Cycle Pedals, H. Lucas, London.
14,048. Boots and Shoes, W. Pulman, Manchester.
14,049. Bicycles, &c., G. Gilbert and E. Mushing, Birmingham.
14,050. Cultivator, G. L. Whiting, London.
14,051. Horse Collars, D. K. Bill, London.
14,052. Public Baths, W. Harpur, Cardiff.
14 053. Tobacco Pipe, J. J. McGhee, London.
14,054. Furnaces for Producing Cyanide of Ammonia, W. Schulte and F. A. Sapp, London.
14,055. Hand-propelled Velocipedes, M. Naletoff, London.
14,056. Manufacture of Azo-colouring Matters, O. Imray.—(*The Farbwerke vormals Meister, Lucius, and Bruning, Germany.*)
14 057. Buckle and Ring for Braces, F. Williamson, London.
14,058. Dry Seats in Wet Weather, F. Wilson, Manchester.
14,059. Attaching Blinds to Rollers, R. E. Ware, London.
14,060. Golf Clubs, A. H. Scott, London.
14,061. Tubing for Conveyance of Grain, F. E. Duckham, London.
14,062. Projectiles for Ordnance, T. Turner, London.
14,063. Reservoir Pens, W. Moyle and J. T. Aitkenhead, London.
14,064. Fuse Head for Blasting, T., W. A. and S. R. Malson, and E. Smith, London.
14,065. Fuse Head for Blasting, W. A., T. and S. R. Malson, and E. Smith, London.
14,066. Writing Slates, A. Haynes and S. Turton, London.
14,067. Apparatus for Mixing Liquids, E. J. B. P. Jodelay and M. J. E. Laurans, London.
14,068. Combustible Composition, R. Odeyn, London.
14,069. Electrical Governors for Water-wheels, C. S. English, London.
14,070. Tacheometrical Instruments, W. H. Beck.—(*J. Donnan, India*)
14,071. Steam Boilers, T. Taylor, London.
14,072. Steam Boilers, T. Taylor, London.
14 073. Steam Boilers, T. Taylor, London.
14,074. Apparatus for Removing Scale from Fire-tubes, H. Baschy, London.
14,075. Time Recorders, J. Dey, London.
14,076. Pipe Wrench, B. A. Hjorth and F. H. Getzmann, London.
14,077. Apparatus for Washing Bottles, W. Beetham, London.
14 078. Manufacture of Metal Bars, A. F. E. Dupont, London.
14,079. Matches, W. Hertz, London.
14,080. Incandescent Electric Lamps, G. F. Redfern.—(*C. Schwabe, Germany.*)
14,081. Fireproof Ceilings and Floors, F. A. P. Stolte, London.
14,082. Apparatus for Measuring Distances, H. Underdown and W. Beeston, London.

*23rd July*, 1894.

14,083. Guide for Rotary Cutters, J. W. Urquhart, Leicester.
14,084. Boxes, Packet Shapes, &c., G. Gibbons, Leicester.
14,085. Plough for Planting Potatoes, S. Watts, Frome.
14,086. Paraffin Boiler, F. W. Beck, East Grinstead.
14,087. Securing Gas and Lamp Globes, J. Allpass, Manchester.
14,088. Safety Appliance for Pit Cages, G. Archer and A. D. Mitton, Nottingham.
14,089. Buckles, J. Walker, Birmingham.
14,090. Furnace Fire Bars, T. Woodward, Nottingham.
14,091. Horse Collars, F. Cook, Glasgow.
14,092. Dyeing and Treating Yarns, F. Barraclough, Yeadon.
14,093. Carts, &c., J. Walmsley and J. Smith, Blackburn.
14,094. Interlining for Coats, &c., W. H. Sladdin, Brighouse.
14,095. Cork Extractors, L. W. Sutcliffe, Manchester.
14,096. Pick and Pick Motion for Looms, J. Sheldon, J. Murray, and W. Smith and Brothers, Limited, Manchester.
14,097. Harness Collars, C. H. Guest and J. Greenall, Leeds.
14,098. Skirt Holder or Suspender, C. H. Hart, Eastbourne.
14,099. Steam Engines, A. Burgess, Coalbrookdale.
14,100. Storage Chest, J. Hatfield and J. Marshall, Hull.
14,101. Tool for Extracting Screw-studs, W. Earl, Newcastle-on-Tyne.
14,102. Golf Putters and Cleeks, W. Lowe and T. Eddleston, Buxton.
14,103. Safety Apparatus for Ropes, H. J. Laybourne, Cardiff.
14,104. Invalids' Bed-gown, M. Byers, London.
14,105. Securing the Keys of Railway Lines, F. Drake and T. H. Aggett, Teignmouth.
14,106. Fastening for Boots and Shoes, T. Hayward, Shropshire.
14,107. Compound Automatic Machine, S. Bryan, Cardiff.
14,108. Driving Gear for Cycles, C. B. Lawson, Glasgow.
14,109. Railway Ticket, C. Stange, Glasgow.

14,110. Steam Water Outlet Appliance, A. Flachsmann, Cologne.
14.111. Dust Protector for Gas Lamps, N. Berlin, jun., Cologne.
14,112. Tires, C. Challiner, Manchester.
14,113. Electrical Energy Meter, A. G. Cooper, London.
14,114. Pumps, F. Edwards. London.
14,115. Sealed Sack and Water Mystery, J. Bracken, Oldham.
14,116. Preventing Smoke in Furnaces, S. A Johnson, London.
14,117. Mechanical Toys' Mechanism, G. F. Lutticke, London.
14,118. Supply of Mechanical Toys, G. F. Lutticke, London.
14,119. Coating the Soles of Boots, &c., E. Hitzel, London.
14,120. Brace or Suspender Fittings, A. Breese, London.
14,121. Changing Photo Films, A. C. and A. A. Smith, London.
14,122. Prepayment Gas Meters, J. Tourtel, London.
14,123. Fixing Electric Bells, W. P. Theermann and G. C. Elliott, Manchester.
14,124. Safes, Cash and Jewel Boxes, A. A. Crozier, London.
14,125. Bottles, J. H. Valentine, London.
14,126. Screw Driver, E. G. Brewer.—(*Messrs. Solomons and Benson, South Africa*.)
14,127. Rotary Engines, J. H. Adamson, London.
14,128. Apparatus for Churning Butter, S. Cheeld, London.
14,129. Churning Butter and Testing Milk, S. Cheeld, London.
14,130. Life-saving Appliance for Boats, W. von Rüdiger, London.
14,131. Gas or Oil Motors, E. T. Owen, London.
14,132. Velvets and Velveteens, G. H. Smith and B. Cooper, Manchester.
14 133. Interceptor Traps for Sewers, J. Barron, London.
14,134. 1 . 4 . 6 and 1 . 4 . 7 α-naphtholdisulphonic Acids, O. Imray.—(*The Farbwerke vormals Meister, Lucius, and Brüning, Germany.*)
14,135. α-naphtholmonosulphonic Acids 1 . 4, O Imray.—(*The Farbwerke vormals Meister, Lucius, and Brüning, Germany.*)
14,136. Printing on Paper or Fabrics, W. Mather, London.
14,137. Colouring Matters, J. C. L. Durand, D. E. Huguenin, and A. J. J. d'Andiran, London.
14,138. Extraction of Eucalyptol, L. R. Scammell, London.
14,139. Spring Eye-glasses, E. Edwards.—(*M. Seiffert, Germany.*)
14,140. Controlling the Admission of Persons into Houses, E. Edwards.—(*M. Hecht, Germany.*)
14,141. Brakes, E. Edwards. —(*A. Klietsch and L. Hoffmann, Germany.*)
14,142. Turning-over Leaves of Music, B. Weedon, London.
14,143. Valves for Pneumatic Tires, C. E. Hüttemeier, London.
14,144. Nozzle for Fire Buckets, C. L. Wilkin, London.
14,145. Construction of Ceilings, &c., J. F. Golding, London.
14,146. Reticulated Metal Work, J. F. Golding, London.
14,147. Construction of Partitions, J. F. Golding, London.
14,148. Cooking Appliances, F. Giles, London.
14,149. Mouldings, F. Stengel, sen., and C. Müller, London.
14,150. Steam Jet Blowers, W. H. Wheatley.—(*A. F. Carman, United States*.)
14,151. Transparent Advertising Tablet, H. S. Fearon, London.
14,152. Bagatelles, A. Brandelet, London.
14,153. Spring Fastener for Gloves, &c., E. Fisher, London.
14.154. Sulpho-cyanides, G. S. Albright and J. J. Hood, London.
14,155. Extracting Metals, J. J. Hood, London.
14,156. Electrical Wagons, O. W. Ketchum, London.
14,157. Fasteners for Sash Windows, W. A. Walpole, London.
14,158. Water Motors, C. C. Leathers, London.
14,159. Extinguishing of Lamps, H. Quaadt, London.
14,160. Clocks, J. Cohen, London.
14,161. Photographing in Colours, J. Joly, London.
14,162. Boiling Starch, J. Hibbert and E. Roberts, Manchester.
14,163. Cycle Frames, C. W. Brown, London.
14,164. Valves Suitable for Pneumatic Tires, H. Hadden, London.
14,165. Boiling Size, J. Hibbert and E. Roberts, Manchester.
14,166. Shuttle-throwing Devices, G. Schwabe, London.

*24th July*, 1894.

14,167. Fish-plates, J. Chaloner and G. Hibbert, Chapel-en-le-Frith, Derbyshire.
14,168. Angle Measuring Instrument, J. W. Shepard, Southampton.
14,169. Whisking or Churning Devices, R. Wood, Glasgow.
14,170. Connecting the Hubs of Wheels, R. Timson, Leicester.
14,171. Tripod Camera Stands, E. Greenhalgh, Manchester.
14,172. Ball Casters, H. Maudsley and F. Painter, Accrington.
14 173. Exhaust Steam-pipe Condenser, R. B. Rigby, Widnes.
14,174. Measuring Small Strains, J. A. Ewing, Cambridge.
14,175. Ring Watch Guardian, C. Alexander, Manchester.
14,176. Fluid for Lithographic Printing, W. Lunn, Birmingham.
14,177. Artificial Baits, S. Allcock, Redditch.
14,178. Flushing Cisterns, T. Atkins, Wolverhampton.
14,179. Baking Powder, G. Weddell, Newcastle-upon-Tyne.
14,180. Anti-frictional Bearings, H. P. Hoghton, Manchester.
14,181. Packing for Stuffing-boxes, W. Watson, Glasgow.
14,182. Salt-sprinkling Vessel, M. Spieldiener, Liverpool.
14,183. Self-sealing Vessels, J. Raab and F. Bingler, Manchester.
14,184. Liquid Heating Apparatus, F. Kleemann, Manchester.
14,185. Blast Furnaces, R. T. Howard and J. Collier, Bolton.
14,186. Propelling Bicycles and Tricycles, J. Hamilton, Loughborough.
14,187. Pulleys or Drums for Preventing the Slipping of Driving Belts or Ropes, J. H. Sunderland, Rochdale.
14,188. Connecting Pipes or Tubes, J. Mills, Manchester.
14,189. Cloth Measuring Indicator, J. H. Cunliffe and G. Hoyle, Rochdale.
14,190. Drawing Boards and Sketching Appliances, R. H. Bentham, Preston.
14,191. Blower for Driving Cycles, S. H. Robinson-Baker, Charleville, Co. Cork.
14.192. Separating Mixed Gases, W. P. Thompson, Liverpool.
14,193. Printing and Dyeing Calico, E. B. Manby, Manchester.
14,194. Guard for Food, E. Lightowler, Southport.
14,195. Sowing Artificial Manures, W. Davidson, Glasgow.
14,196. Coke Ovens, A. D. Shrewsbury, Glasgow.
14,197. Pads for Rupture Trusses, A. G. Wing, Weston-super-Mare.
14,198. Plating of Saddle Trees, R. Flemming, London.
14,199. Eye for Fixing Stair-rods, G. Y. Iliffe, Birmingham.
14,200. Children's Savings Banks, M. Cole, London.
14,201. Grass Mowing Machines, G. Kearsley, E. King, and W. Shepherd, Sheffield.
14,202. Signalling, H. D. Fitzpatrick.—(*The Boughton Telephotos Company, United States*.)
14,203. Letter and Bill Files, W. O. Gottwals, Ottawa.
14.204. Couplings for Vehicles, A. Fürst and J. Wellner, London.
14,205. Cigarette Holders, A. J. Boult.—(*H. Müller, Germany.*)
14,206. Covers for Typewriters, J. C. W. Stanley and W. W. Hughes, London.
14 207. Boxes, J. C. W. Stanley and W. W. Hughes, London.
14,208. Spinning Machines, C. B. Holland and J. Fraser, London.
14,209. Stocking, H. Wildt, London.
14,210. Drying Cement, W. W. Hughes, London.
14.211. Treadles for Velocipedes, G. A. Jeffery, London.
14 212. Printed and Painted Fabrics, F. Boyer, London.
14,213. Watches, J. G. Sanders, Edmonton.
14 214. Cloth Caps, E. Hope, Manchester.
14,215. Rectifying Sulphuric Acid, J. W. Scott, London.
14,216. Steam Boiler Furnaces, W. and R. Woodward, Manchester.
14,217. Coin-controlled Machines, H. H. Lake.—(*J. P. Tirrell and J. W. Willard, United States*.)
14,218. Coin-controlled Machines, H. H Lake.—(*J. P. Tirrell and J. W. Willard, United States*.)
14,219. Labelling of Bottles, G., J. G., and M. O. Rehfuss, London.
14,220. Lasting Machines, H. H. Lake.—(*C. S. Luitwieler, United States.*)
14,221. Bottles and Stoppers, L. Kalling, London.
14,222. Buffing of Boot Soles, H. H. Lake.—(*A. W. Rogers and S. W. Winslow, United States*.)
14,223. Dyeing Fibre, H. H. Lake.—(*M. E. Waldstein, A. H. Peter, and E. Spott, United States.*)
14 224. Making Photographic Negatives, B. McF. Clinedinst, jun., London.
14,225. Overhead Sewing Machines, W. Webster, London.
14,226 Fire Ranges, C. Hattersley, London.
14,227. Sausage-filling Machines, F. J. Gardner, London.
14.228. Manufacturing Carbonic Acid, &c., E. W. Enequist, London.
14,229. Photographic Apparatus, G. G. Hardy, London.
14,230. Mechanism of Sewing Machines, J. White, London.
14,231. Sewing Machine Spool-holders, J. White, London.
14,232. Deadening Noise in Motors, F. L. Serment, London.
14,233. Machine Gun and Carriage, W. H. FitzGerald, London.
14,234. Lamps for Public Lighting Purposes, A. Dessy, London.
14,235. Syphons, R. Thayer, London.
14,236 Car Brake Systems, H. A. Clark, London.
14,237. Cash Registers, A. H. Miller, London.
14,238. Apparatus for Flattening Rice, E. S. Spencer, London.
14,239. Mattresses, E. Edwards. — (*I. Abrahamsen, Denmark.*)
14,240. Waking Persons Electrically, W. Wilke, London.
14,241. Diary, E. J. Harvey, Beckenham.
14,242. Valves, &c., J. T. Marshall and R. Wigram, London.
14,243. Steam Jet Apparatus, C. F. Kierzkowski-Steuart, London.
14,244. Plumbing Seals, B. von Possanner-Ehrenthal, London.
14,245. Brake-blocks, A. Köberling and H. Höhrmann, London.
14.246. System of Electrical Distribution, C. F. Scott, London.
14,247. Portable Case of Shelves, A. S. Tomkins, London.
14,248. Controlling Sale of Tickets, J. Olsen and J. Craig, London.
14,249. Camphor, A. M. A. F. E. van Dyck, London.
14,250. Wax Thread Sewing Machines, H. F. Nason, London.
14.251. Sash Fasteners, A. J. Ball and J. de Courcy Hickton, London.
14,252. Gun-carriages, W. B. Gordon and T. R. Morgan, sen., London.

*25th July*, 1894.

14 253. Detachable Handle for Paint-pots, C. Cox, London.
14,254. Bandage, G. Palme, London.
14,255. Dust Excluder for Doors, &c., J. Hayward, Sussex.
14,256. Bell, C. J. Vincent, Truro.
14,257. Swimming Appliances, W. Snaydon, Dorchester.
14,258. Can-openers, A. Clowes, Birmingham.
14,259 Self-feeder for Chaff-cutters, J. Osborn, St. Neots.
14,260. Game, H. O. Roberts, Gloucester.
14,261. Bolsters or Holders for Spindles, E. Hitchon, Accrington.
14 262. Device for Retaining Stockings, A. J. Heys, Manchester.
14,263. Joining the Rims of Cycles, E. C. Wasdell, Birmingham.
14,264. Hair Curlers, H. H. Pearce, Birmingham.
14,265. Machines for Heading Nails, H. W. Tonks, Birmingham.
14,266. Fastening Pneumatic Tire Coverings, J. Parr, Leicester.
14,267. Self-heating Smoothing Iron, T. T. Tuttle, London.
14,268. Carving-fork Guards, J. E. Bingham and A. B. Ball, Sheffield.
14,269. Bicycle Lamp, S. G. Watson, Birmingham.
14,270. Extracting Corks from Bottles, J. F. M. Pollock and W. Leach, Leeds.
14,271. Securing Table Cutlery Handles, T. S. Fenton, Sheffield.
14,272. Rolling Wires, Bars, &c., G. Goldthorpe, Halifax.
14,273. Securing Door Knobs, J. T. Stanyon, Chertsey.
14,274. Winding Cotton, J. Haydock, jun, and J. Haydock, Glasgow.
14,275. Scouring Slivers of Fibrous Material, J. Rhodes, jun., Bradford.
14,276. Weaving Shuttles, J. Waddington, Bradford.
14,277. Shutter for Photographic Cameras, D. Morgan, Bristol.
14,278. Cinder Sifters, J. Stranaghan, Manchester.
14.279. Focussing in Optical Lanterns, W. Lawson, Manchester.
14,280. Brackets for Blinds, R. Pill and T. Pill, Manchester.
14,281. Focussing Appliance for Photographic Cameras, E. G. B. Barlow, Glasgow.
14,282. Chains, H. Schlieper, jun., London.
14,283. Holding the Cords of Venetian Blinds, J. F. Williams, Cheshire.
14,284. Distributing Oil from Ships' Sides, D. J. Jenkins and S. Carey, Dartmouth.
14,285. Strainers for Tea-pots, A. G. Hewitt, Birmingham.
14,286. Machines for Making Envelopes, J. Ball, Manchester.
14,287. Wire Weaving Power Looms, J. Telford, Manchester.
14,288. Game, A. W. Treen, London.
14,289. Device for Holding Knives while Cleaning, E. J. Hallam, London.
14 290. Electrical Lamp Holders, G. Binswanger, London.
14,291. Applying Heat to the Human Body, W. S. Hedley, Brighton.
14,292. Pneumatic Tires for Velocipedes, J. Litherland, London.
14 293. Anti-Germanite Tablet, F. G. Hargan, London.
14,294. Controlling the Consumption of Gas, A. Whittall, Birmingham.
14 295. Rustic Wood Arbours, G. Bayliss and A. Inman, Birmingham.
14,296. Filing Nails in the Heels of Boots, J. Lee, London.
14,297. Obtaining Combustion in Furnaces, W. Esplen, Liverpool.
14,298. Mudguard for Cycles, R. M. Crabbe, Liverpool.
14,299. Thick Soft Absorbent Cloth, W. Pickstone and A. Greenhalgh, Manchester.
14,300. Valves for Pneumatic Tires, W. P. Thompson.—(*A. Knuss and M. Härter, Germany*.)
14,301. Lamps, J. S. Byrne and J. T. Steele, Liverpool.
14,302. Buckles or Clasps for Braces, A. W. Patching, Manchester.
14,303. Electricity Motor Meter, C. Raab, Liverpool.
14 304. Flour Manufacture, T. T. Vernon, Liverpool.
14,305. Cases for Oil Heaters, J. Harper and Co., Ld., and C Retallack, London.
14,306. Galvanising Metal Sheets, Davies Brothers and Co., Ld., E. A. Davies, and S. T. Thomas, London.
14.307. Fancy Sealing Wax, E. G. Smith and E. A. Still, London.

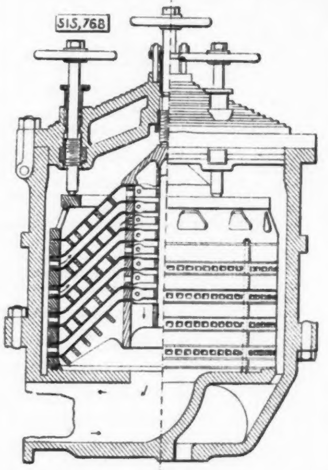
## SELECTED AMERICAN PATENTS.

*From the United States Patent Office Official Gazette.*

**516,768.** Breech Mechanism for Ordnance, *O. F. Leibert, Bethlehem, Pa.—Filed November* 1st, 1893.

*Brief*—The breech plug has a curved and a straight rack upon it which are engaged by a compound operating wheel provided with teeth having worm faces and spur or pinion faces.

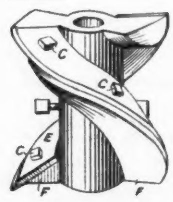
515,768



**516,776.** Wood-working Machine, *J. H. Soars, Muncy, Pa.—Filed July* 1st, 1893.

*Claim.*—In a cutter head for wood-working machines the combination of a solid lip F, having on its top or upper side placed at a suitable angle a plane or flat surface from the body of the head to its outer edge, being spiral lengthwise and radial in any plane of cross section, and milled out on the bottom or under side in a spoon shape forming a clip breaker, with an adjustable flat curved knife E spiral longitudinally and running radially to the head viewed in any particular plane of cross section and made to conform to and fit closely on the top of the lip F, beveled backwardly on its top or upper side, having slots G therein for adjusting the knife on the lip F, and fastened thereon by the use of knife bolts C, passing through the slots G into the lip F ; all substantially as described.

516,776.



**516,840.** Electrically-operating Pump, *C. Robinson, Lynn, Boston, Mass.—Filed October* 11*th*, 1893.

*Claim.*—(1) The combination of an electric motor driving a pumping apparatus, the casing of which forms a part of the magnetic circuit of the motor, such casing being provided with channels and valve mechanisms adapted to assist the circulation of the fluid from the pump. (2) The combination of a casing having interior and exterior channels, field magnets of an electric motor connected by such casing and having field magnet cores projecting through the channels, an armature for such motor, and pumping mechanism operated thereby ; whereby the circulation of the fluid through the casing acts to cool the field magnets of the motor and increase the efficiency. (3) The combination of a casing forming a magnetic yoke, field magnets of an electric motor connected thereby, and a rotating armature driving pumping mechanism adapted to force water or other fluid through the casing, such casing being formed with interior and exterior channels, and with consequent pole pieces, as $B^3$, between the field magnets, all as described and set out herein. (4) The combination of a casing, as A, provided with an intake, as D, an interior channel, as L, valve mechanisms, as N O, an exterior channel, as K, an exit, as E, reciprocating pistons, as F F, a revolving armature, as T, field magnets secured to the casing and having their cores projecting through the channels therein, and consequent poles, as $B^3$, formed in the casing and having one of the channels arranged to circulate the fluid through them, all arranged substantially as herein set out and described.

**516,896.** Valve Gear for Duplex Direct-acting Engines, *H. W. Morley, Bradford, and T. Holehouse, Chorlton-cum-Hardy, England.—Filed June* 22*nd*, 1893.

*Claim.*—(1) In a duplex direct-acting engine, the combination of oscillating levers D and E, actuated by the crossheads C and C' respectively, the lever E oscillating on a movable stud K, controlled by the lever D for the purpose of regulating and controlling the admission valve V of the cylinder A, all arranged substantially in the manner as shown and described. (2) In a duplex direct-acting engine, wherein the valve gear for regulating and controlling the valves V and V', consists of operating levers E and E', actuated by piston-rods B and B' respectively, and fulcrumed on movable studs K and K', the position of which said studs is controlled by levers D and D', respectively actuated from the contrary piston-rods B' and B, the combination therewith, of variable cut-off valves actuated from their respective piston-rods, substantially as described. (3) In a duplex direct-acting engine, the oscillating levers D and E actuated by crossheads C and C' respectively, the lever E oscillating on a movable stud K controlled by the lever D for controlling the admission valve V of the cylinder A, valves V V actuating levers therefor and means for varying the movement of said valves, substantially as described. (4) In a duplex direct-acting engine, wherein the valve gear for regulating and controlling the valves V and V', consists of operating levers E and E' actuated by piston-rods B and B' respectively, and fulcrumed on movable studs K and K', the position of which said studs is controlled by levers D and D', respectively actuated from the contrary piston-rods B' and B, the combination therewith of slotted crossheads C and C', fitted with movable blocks for the purpose of varying the ratio of the levers D and D', and E and E', all arranged substantially in the manner as shown and described. (5) In a duplex direct-acting engine, the oscillating levers D and E actuated by the cross-heads C and C' respectively, the lever E oscillating on a movable stud K controlled by the lever D the valve V and controlling lever F and a connection between the valve V and operating levers providing for a slack action, substantially as described. (6) In combination with the oscillating levers D and E actuated by the crossheads C and C' respectively, the valve rod F and valve V, and means for moving the fulcrum of lever D horizontally against spring pressure, substantially as described.

## NOTES ON THE STRENGTH OF FRAMED STRUCTURES AS AFFECTED BY ELASTICITY.

By C. F. Findlay, M.A., M. Inst. C.E.

In the design of girders and other framed structures, it is customary to ignore altogether the elastic properties of the material, except in cases such as that of the continuous girder, where no solution can be obtained of the question of the distribution of stress, without considering those properties. In England and America there is also a prejudice amongst engineers against the adoption of such designs as do not admit of the direct application of statical rules without reference to elasticity. This prejudice appears to be diminishing, and the fact of its diminution may be attributed largely to the example of continental practice where metallic arches and continuous girders have been built for large spans in great numbers, their strength being calculated with perfect confidence. Experience has justified that confidence as fully in regard to those structures as in regard to simple trusses.

In point of fact, there is no such broad line to be drawn between one class of frames and the other as is supposed by those who simply design by formulæ, without inquiring how the formulæ are arrived at. The ordinary statical rules by which force applied at a point is balanced by stresses along various bars, which stresses, at the intersections with other bars, are again resolved in various directions, pre-suppose elastic properties in the various links. Just as force is an abstract conception that we have invented to assist our ideas in connection with the motion of bodies, so stress which we talk about as if it had a real existence outside our own minds, is only a conception we have formed in connection with the visible strain of bodies. The existence of stress in a body without strain is rather unthinkable than impossible.

These statements may possibly be regarded as mere truisms, but there is an important practical conclusion to be drawn from them, viz., that it may be worth while to examine the magnitude of the errors introduced by the various hypotheses made in order to simplify the calculation of the strength of frames to the point where the elastic properties need not be taken into account. We do not propose in these notes to enter into the general question of elastic theories as applied to arches, continuous girders, frames with redundant members, &c. This has already been done in many treatises—although the English language is deficient in this respect as compared with French and German. What we propose is to give an idea of some of the principal corrections that ought to be applied to calculations made by statical rules, and to show how a study of the elastic properties of frames may assist in the decision of questions relating to them, which are otherwise indeterminate. We shall give numerical calculations to illustrate the principles we may establish, so as to enable the reader to judge for himself how far the principles are of practical importance for purposes of design.

The assumptions tacitly made when the stresses in a frame are determined by statical rules may be broadly divided into three classes, as follows, viz.:—(1) That the frame consists of links united by frictionless hinges. (2) That the links are all perfectly straight and remain straight when strained, their axes* of figure meeting at one point for each joint. (3) That the external forces and reactions are known as to magnitude and direction, and are applied only at certain joints of the frame. This assumption in general implies that the frame is fixed at one point of support, that another of its points is free to move without resistance along a given line, and that otherwise the frame is free from constraint.

### Section I.—Secondary Stress.†

The stresses in framed structures with riveted joints are, in practice, calculated on the assumption that the joints are frictionless hinges. Calling the stresses so calculated the "primary stresses," the name "secondary" is usually given to the additional stresses arising from the invariability of the angles between the different members of the structure meeting at any joint, and we shall use the word in that sense. In most bridges there are stresses of the same nature, caused by the fact that the axes of figure of the various members meeting at any one joint do not intersect at one point; the stresses from this cause are so large sometimes as to be a serious danger,‡ but they are not included among the secondary stresses to be here considered. The fact that the secondary stresses—as above defined—in bridges are not as a rule calculated even in the most important structures, can only be explained by one of two reasons. Either they are supposed to be so small as to be negligible, or else to be beyond the range of calculation with ordinary skill and labour. We hope in the present articles to do something to dispel the latter impression. In regard to the former it may be sufficient to say that the secondary stress is very frequently in excess of the primary stress—in absolute amount—in some of the web members of a girder; the actual stress as compared with the primary stress being thus reversed on one edge of the member from tension to compression, or *vice versâ*, and on the other edge more than doubled in amount. In the booms the secondary stress rises to 25 per cent. of the primary stress in the case of a representative English bridge—referred to below—and may often be much more. The calculations giving these results are based on principles which are universally accepted; they are confirmed by the very valuable measurements made by M. Charles Rabut, on the bridges of the Chemins de Fer de l'Ouest in France, described in *Le Génie Civil*, vol. xxii., 1892, page 88, and of which a short summary is given in the foreign abstracts of the Proceedings of the Institution of Civil Engineers, vol. cxii., page 391. Not only are the secondary stresses of so large an amount that an approximate determination of them would be a considerable addition to our knowledge of the strength of structures; but also they vary to so great a degree from one bridge to another, according to the general and detail design adopted, that even where these stresses are not calculated a knowledge of the general laws which govern them may be a valuable aid in design.

The following two propositions embody the information necessary for determining secondary stresses in general.

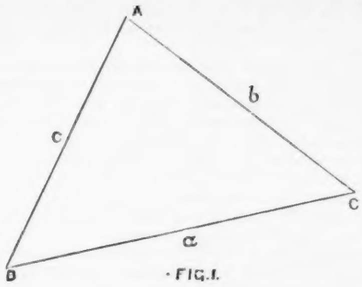

FIG. 1.

If the triangle A B C form part of a hinged framework in its unstrained state, and the angle A becomes A + Δ A by reason of the deformation of the triangle, then

$$E \times \Delta A = (t_a - t_b) \cot C + (t_a - t_c) \cot B \quad . \quad \text{(I.)}$$

where E is the modulus of elasticity (supposed uniform), and $t_a$ $t_b$ and $t_c$ are the stresses per unit of sectional area in *a b* and *c*, the area being reckoned without deduction for rivet holes. A stress is considered positive when tensional because it produces a positive increment of length in the link affected, and E is in the same units as $t_a$ $t_b$ and $t_c$ (say tons per square inch).

If any number of links whose axes of figure in the unstrained state are straight lines, O A, O B, O C, O D, &c., are united at O, so that the angles between them are invariable, and if $\theta_{12}$ be the increase which would take place in the angle A O B with frictionless hinges at all the joints, then

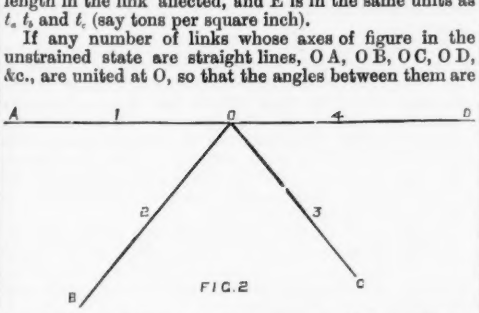

FIG. 2

$$6\,E \times \theta_{12} = \frac{l_1}{I_1}\,(2\,M^1_0 - M^1_A) - \frac{l_2}{I_2}\,(2\,M^2_0 - M^2_B) \quad \text{(II.)}$$

where $M^1_0$ denotes the bending moment at O in the link 1, and $M^1_A$ the bending moment at the other end of the same link, $l_1$ and $l_2$ the lengths of the links, $I_1$ and $I_2$ the moments of inertia of their cross-sections (supposed constant). For determining the signs of $\theta$ and M in equation (II.) rotation contrary to that of clock-hands is, as usual, considered positive. This equation ceases to be approximately true when the transverse dimensions of a link are very small compared to its length. The exception is of no practical importance, because in those cases the secondary stress is so small that we have no occasion to calculate it.

The proofs of these two propositions will be given in an appendix, and it will be seen that Equation (II.) is obtained on the assumption that $\frac{t\,l^2}{E\,\rho^2}$ is not large (say less than unity), $\rho$ being the radius of gyration of the cross-sectional area of any link whose length is $l$ and stress $t$. For instance, if $t = 4$ tons per square inch, and $E = 13{,}000$, the ratio $\frac{l}{\rho}$ should not exceed 55 to 60 in order that Equation (II.) may be applicable. Or, take the case of the American bridge referred to below. The vertical post 10 is 25ft. in length, and has $\rho =$ about 4in., so that $\frac{l}{\rho} = 75$, while $t$ is $1\frac{1}{2}$ tons per square inch, so that with wrought iron with E, about 11,000 tons, the fraction will be nearly $\frac{8}{11}$, and Equation (II.) will apply. For the eyebars in the same bridge, the values of M obtained by applying Equation (II.) although small, are very much larger than the true values.

If there are $n$ links meeting at O, we have $n - 1$ equations similar to (II.) and also the relation:

$$M^1_0 + M^2_0 + \&c. + M^n_0 = 0 \quad . \quad . \quad . \quad . \quad \text{(III.)}$$

Taking the whole frame, we have therefore as many equations as unknown quantities M. The left-hand side of Equation (II.) is given by (I.) without much labour, and $\frac{l}{I}$ can be easily calculated for each link. When this has been done the values of M could be at once written down as determinants. The evaluation of these determinants rigorously would in most cases, however, be a very formidable task, and we shall presently show how, for practical purposes, sufficiently approximate values can be obtained with no great amount of arithmetical computation. Before doing so we may call attention to a few results of importance flowing immediately from (I.) and (II.)

(1) The secondary stresses are independent of the modulus of elasticity (so long as the latter is uniform). This follows from the fact that Δ A enters into both equations in the form E × Δ A. The deformations, both linear and angular, are inversely proportional to E, but the bending moments caused by a given deformation being directly proportional to E are, when expressed in terms of the primary stresses, independent of E.

(2) The secondary stresses in any frame are a constant fraction of the primary stresses (and therefore proportional to the load), so long as the distribution of the load remains the same.

(3) The angular deformations at the joints are independent of the linear dimensions of the frame so long as the angles between the links are unaltered. Compare, for example, two parallel girders of the same span with horizontal booms and bracing at the same angles, the stresses per square inch employed being the same, but the depth of one girder being twice the depth of the other. The changes in the various angles will be the same in both girders, but the shallower girder will have a central deflection approximately double that of the deeper girder, owing to the greater number of joints. In Equation (II.) the left-hand side is the same for both girders, but on the right-hand side $l$ has for the shallower girder half the value it has for the deeper, which doubles all the values of M; and further, I will probably be greater in the shallower girder for all the boom members, because the stress is doubled, and this leads to a further increase in M. We thus see, in regard to secondary stress, the great advantage in using a deep girder. In fact, when a triangulated girder is very shallow, the ordinary calculations based on the assumption of hinged joints give an altogether false idea of the stresses in the girder, and the instinctive preference of engineers in such cases for a plate girder has thus a rational justification.

(4) The deformation to which the booms are subjected in parallel girders depends comparatively little on the nature and angles of the bracing, but mainly on the stresses in the booms and on the depth of the girder.

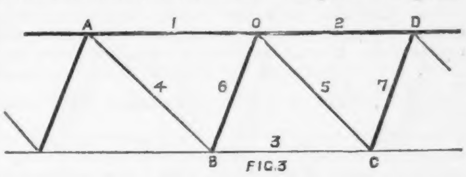

FIG. 3

Consider the girder of which A B C D represents a part. The angular deformation of the boom A O D at O is given by successively applying Equation (I.) to the three angles A O B, B O C, C O D. Now, in most cases the stresses in corresponding members of successive panels will not differ much from each other. Assume, then, that $t_1 = t_2$, $t_4 = t_5$, and $t_6 = t_7$. It will be found that $t_4 = t_5$, $t_6$ and $t_7$ disappear, and if $\theta_{12}$ be the angle between A O and O D under strain,

$$E\,\theta_{12} = (t_3 - t_1)\,(\cot\alpha + \cot\beta) = \frac{g}{p}\,(t_3 - t_1) \quad . \quad . \quad \text{(IV.)},$$

if $g$ be the length of the panel and $p$ the depth of the girder. In other words, the angular deflection of the girder per foot run of length is $\frac{t_3 - t_1}{E\,p}$. If $t_3$ and $t_1$ be constant throughout the girder, the angular deflection at the abutment of a span of length $2\,l$ is $\frac{l\,(t_3 - t_1)}{E\,p}$, and the linear deflection in the middle is approximately $\frac{l^2\,(t_3 - t_1)}{2\,E\,p}$, which is the same as the deflection obtained by the usual theory of flexure for a beam of the same span and of constant depth and flange stress, whereas for a beam of constant moment of inertia the deflection is five-sixths of the same quantity. The expression arrived at in Equation (IV.) above for the deformation of the boom does not apply to the middle of the span. The deformation of the flanges at the middle of the span will be greater than at any other point, and it may be said generally that the deformation of the flanges of any girder will be greatest at the point where the shearing stress changes sign, as, for instance, in a continuous girder at the supports.

(5) It is clear from equations (I.) and (II.) that the secondary stresses will vary very much from one member of a frame to another by reason of the great variations in the angular deformations $\theta$, and of the coefficients $\frac{l}{I}$. Considering Equation (I.), we observe that of the three quantities $t_a$, $t_b$, and $t_c$, two are always of the same sign, and the third of the contrary sign. Of the three angles A B and C—Fig. 1—that one will be in general most deformed by the strain which is included between the two links affected by stress of the same kind. Applying this to any of the triangles of the girder in Fig. 3, we see that the angles which suffer the greatest deformation are those made by the compression diagonal with the upper boom, and by the tension diagonal with the lower boom. The latter is of smaller importance, because the two links enclosing the angle being both in tension, they should be of small width, and will in that case have no large secondary stress. The former angle, being enclosed between two compression links, which must necessarily be of considerable width, gives rise to important stresses in the diagonals, and the arrangement adopted for the bracing may considerably affect these stresses. If it be desired to reduce as far as possible the deformation of the angle between the compression diagonal and the upper boom, this object will be obtained by placing the tension bars vertical, or nearly so. This may be seen by applying Equation I. to one of the triangles in Fig. 3, and making the value of $\theta$ a minimum, subject to the condition that the depth and panel length of the girder are constant, when it will be found that the minimum value is given by the relation—

$$\frac{\tan\alpha}{\tan\beta} = \frac{t_6 - t_1}{2\,t_3 - (t_6 + t_1)}$$

$t_1$ is usually greater numerically than $t_6$, and since $t_1$ and

---

* We use the term "axis of figure" for the line passing through the centres of gravity of the areas of all cross-sections of any link.

† A chapter is devoted to this subject in Winkler's "Vorträge uber Brückenbau;" but it is not dealt with in any English work with which we are acquainted. The method here given is different from Winkler's, though of course identical with it in principle.

‡ See report by Professor Ritter and Tetmajer on "The Moenchenstein Bridge Disaster"—The Engineer, December 4th and 11th, 1891.

$t_8$ are both negative, we see that tan $\beta$ is large, or that A B is nearly vertical. Other considerations, however, which are of greater importance prevent this arrangement of bracing from being adopted in practice, but in the Warren girder, consisting of equilateral triangles, it is approached. If such a girder be compared with another having vertical posts, and tension diagonals at 45 deg., the deformation of the angle between the posts and the upper boom is less in the former girder than in the latter in the ratio of 1 to 1·7, and if the sections used were the same, the secondary stress in the posts would vary in pretty much the same ratio.

(6) Where the frame is irregular, or the angles of the bracing vary from panel to panel, a graphic method of ascertaining deflections and other deformations may be preferred to arithmetical calculation, and Equation (I.) indicates a readily available graphic method, since it may be written in the form,

$$\Delta\ A = \left(\frac{\delta a}{a} - \frac{\delta b}{b}\right) \cot C + \left(\frac{\delta a}{a} - \frac{\delta c}{c}\right) \cot B,$$

where $\delta a$, $\delta b$, and $\delta c$ are the changes of length in the links. If, then, $\delta a$, $\delta b$, and $\delta c$ be magnified $m$ times, the result is to magnify $\Delta$ A $m$ times. Therefore, if, in a diagram of the frame, the lengths of all the lines be increased or diminished by quantities proportional in any constant ratio to the actual changes of length in the various members, the resulting diagram will give correctly the angular deformations multiplied by a factor depending on the scales used both for the diagram itself and for the alterations of length. The only proviso is that the proportional change in length of the lines in the diagram must be small. As $t$ is always known for each link, it is better to avoid introducing E in drawing such a diagram, and it is unnecessary because E is a common factor. Suppose, for instance, the diagram is drawn on a scale of 5ft. per inch, or $\frac{1}{60}$th, and that the scale of strains is chosen such that each line on the diagram becomes altered by $\frac{1}{200}$th part of its length for every ton per square inch of stress in the corresponding link; then $\Delta$ A$^1$, the increment of any angle A$^1$ in the diagram, is $\frac{E \times \Delta A}{200}$, where $\Delta$ A is the deformation of the actual angle in the frame. With the scales here suggested, the angular error (apart from errors of drawing) may have a maximum value of about 5 per cent. If a smaller scale were used for the strains, the errors of the method would be less, but the probable errors of drawing would increase. The diagram of deformation must be adjusted to the fixed points and fixed line of the frame, if it is desired to scale from it linear deformations (as, for instance, the central deflection). Fig. 4 is a simple case of such a diagram drawn to the scales suggested above. The truss is supposed to be fixed at A, and free to slide horizontally at B. The linear deformations of the truss can be scaled from the diagram to $\frac{E}{12{,}000}$ times their true value, where E is in tons per square inch, and the angular deformations to $\frac{E}{200}$ times their true value.

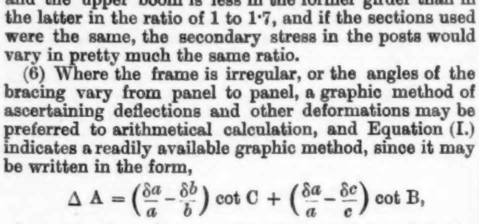

FIG. 4

(*To be continued.*)

## INSTITUTION OF MECHANICAL ENGINEERS.

In our report of the meeting at Manchester, published in our last impression, we gave an account of the proceedings down to Wednesday afternoon, but the two papers referred to as read on that day, with the discussions, we had to defer until to-day. The first of these papers was by Mr. Henry Barcroft, entitled, "Description of Twin Screw Propellers with Adjustable Immersion fitted on Canal Boats."

During the discussion on Mr. Barcroft's paper,

Captain Longridge said with regard to driving by gear wheels, it was objectionable where they ran at high speeds.

Mr. Robinson said he would like to know what led Mr. Barcroft to adopt the method of keeping the propeller only partially immersed. He thought the propellers were much too large for the work they had to do, and if they were put lower down greater efficiency would be obtained. Then with regard to the blades, why had the writer made them so broad, and was the pitch uniform or varying? There was also the question of "wash." It appeared to him that with a propeller working out of the water they would have more wash than when it worked under the water, and he could not see that the propellers situated as described would be less likely to get clogged with weeds. As to the application of electricity, he thought the number of transformations which would have to be gone through, from the dynamo to the motor, from the motor to all the gearing, would prevent the proper working of such a method.

Mr. Aspinall thought there should be an arrangement for taking up the thrust of the propellers.

Mr. Parker did not think the suggestion of the author as to electricity was a very good one.

Mr. Platt thought the method described in the paper was a very good one for applying to existing barges built in the ordinary way.

Dr. Edward Hopkinson was of opinion that the dynamo and motor suggested by the author might be successfully applied. A good way would be to apply, instead of the boiler and engine, a small motor with an overhead system of wires.

Mr. Head considered skew wheels quite unobjectionable when used in ordinary gearing, but when used to convey the whole power of the engine, they worked very unsatisfactorily.

Mr. Chas. Proctor said the injury done to the banks of the canals might be avoided in future by walling them in, so that no "wash" would do any harm. It might interest them to know that he and the late Mr. H. J. Martin had been engaged in trying to facilitate the traffic through the Midlands to the various ports, by having an engine which could easily be transferred from one boat to another.

Mr. B. A. Dobson said he had always taken a great interest in canal boats, and anything that tended to reduce the cost of haulage must be a great advantage. Mr. Barcroft had evidently tried to make the simplest arrangement that could be applied to existing canal boats, and he thought he had pretty well succeeded. As to the gearing which had been adversely criticised, he had found as a matter of practice that if they would keep worm gearing properly oiled it was about as good as anything they could possibly get to do the work. With regard to the propellers, it seemed to him that the slow surface speed at which they were run was admirably calculated for canal work; the wash would not be so great, and there would not be the objection to taking down the air as with an ordinary propeller. The question of the wash on the sides of the canal was most important, and he might mention a device he saw recently on a canal boat in France, by which the wash was entirely avoided. A shield was fixed just outside the propeller, and threw the water aft, so that it lost its speed before touching the banks.

Mr. Tweddale remarked that he had seen a similar shield in this country thirty-two years ago, which, in addition, was utilised for steering the boat; it worked very successfully at the trial, but he never heard of it afterwards.

Mr. Paul thought the fact stated in the paper, that the propeller, had little or no influence upon the steering of the vessel, necessarily involved the inefficiency of the propeller. Further than this, it had been universally found that when the top of the propeller approached even near the surface of the water its efficiency was materially decreased, and that if it actually broke the surface, there was a loss of 25 per cent. of efficiency, and he did not see how all this experience could be reversed by the system adopted by Mr. Barcroft.

Mr. Richards said it always appeared to him that the great desideratum was as far as possible to use a very fine pitch propeller, the result being that the flow of the water was directed aft, and this prevented the side wash which was so objectionable.

Mr. Stern referred to a system of propulsion on the Erie Canal in which a shield was placed round the propeller to break the wash.

Mr. Corley said the conditions for narrow canals were quite different from those met with on boats in open water. Canal engineers appeared to be very divergent in their views as to the best conditions of working.

Mr. Richmond referred to the delay in closing lock gates, which might cause damage to such a propeller as proposed.

Mr. Rogers said he had been making some propellers for electric launches on the Thames with very small pitch, and it had been found to answer admirably, there being little or no wash on the banks of the river. The principal advantages of the method he had adopted were the quick speed and very small pitch.

In replying upon the discussion,

Mr. Barcroft said the skew wheels used were very convenient, and the loss of power was not material. The total mileage run up to the present was 6000 miles, and 300 in waterways in Ireland. In passing through the locks there had been no accidents, and with regard to the waste of time in locking, he had once taken the time in going through the Grand Canal, and found it to be about 1½ minutes, so that the loss of time would not be very serious. The slip became greater in proportion to the narrowness of the canal, varying from 4 per cent. in one, to 68 per cent. in another, the waterway being in the latter case only very little larger than the section of the boat.

The President said he was doubtful whether the critics had quite realised the whole of the difficulties Mr. Barcroft had to encounter. It was one thing to design a marine engine for a ship, and another to design engines that should drive propellers for a barge, and only those specially engaged in the latter work could understand the difficulties lying in the way.

The Secretary next read a paper by Mr. Wm. Thos. Olive, describing the Manchester Main Drainage Works, in connection with which he is the resident engineer.

The reading of the paper was followed by a short discussion, during which

Mr. Charles Hopkinson said the author had forgotten to mention that the attention of the Manchester Corporation was called to the flood question in the fifties, and by 1872 a large amount of money had been spent in building substantial river walls along the banks of the river Medlock. The most serious flood on the rivers in Manchester was that of 1866, on the Irwell, and it was this flood that stimulated—more than any other—the action which had since been taken. He wondered why, with an indefinite quantity of condensing water, the engines described in the paper had not been made condensing, and they ought surely to get more than 70 per cent. of efficiency out of their accumulators, when there were numerous makers who would guarantee more than that.

Mr. Elliott, in the course of some interesting remarks with reference to the sludge presses, said those erected at Davyhulme, although not perhaps quite new in design, were new as regards carrying out the arrangement on any large scale. One feature to be noticed was the closing of the presses, and keeping them closed by hydraulic power. In the ordinary press, as generally used, the closing of the press in order to resist the internal pressure of the sludge forced into it, had usually been effected by means of nuts, and inasmuch as the pressure to be resisted was very great, there had been very considerable manual power required to close the press and make it tight. This work was now being done at Urmston by hydraulic cylinders, which not only closed the presses, but kept them closed. It might interest them to know that the actual work each of the presses was capable of turning out, with the sludge found at Urmston, was about one ton per hour. With regard to the quantity of lime used, this varied at different seasons with the districts from which sewage was coming, and the area from which sludge came to the works had varied to some extent, but the actual quantity of lime used per million gallons of flow appeared to have been about 12 cwt.—which would compare very favourably with the use of lime in many other places where sludge was treated. The arrangements for keeping the hydraulic pressure upon the presses were made to control the supply of sludge to them, so that if by the bursting of a leather of the accumulator it should quickly come down before the people in the press-house were aware, the supply of sludge would be cut off automatically by the falling of the accumulator.

Mr. Olive, in replying upon the discussion, said with regard to the sludge that was dealt with, the farmers in the neighbourhood had so far been only too glad to take it away almost as fast as they made it. They had now, however, an old river course in which they could deposit the surplus sludge; the sewage varied enormously in character, some of it being very difficult to deal with in the presses.

The proceedings in connection with the summer visit of the Institution of Mechanical Engineers to Manchester were on Thursday and Friday devoted entirely to visiting various works in the immediate vicinity of Manchester, and to excursions to several of the important engineering centres in the neighbourhood.

One of the largest parties, numbering upwards of two hundred, was conveyed on Thursday by special train to Oldham, where the morning was spent in a visit to the Lion Spinning Mill at Royton, which is one of the best examples of a modern Lancashire cotton mill. The mill, which is 355ft. long and 129ft. broad, contains 107,000 mule spindles, with the necessary carding and other preparation machinery, which has all been supplied by Messrs. Platt Bros. and Co., Oldham. The driving engines are of the high-speed compound horizontal type, 2000 indicated horse-power. The high-pressure cylinders are 27in. diameter, and low-pressure 46in. diameter, all 5ft. 6in. stroke, making 75 revolutions per minute. The fly-wheel, which is 22ft. diameter, is grooved for forty cotton ropes of 1⅝in. diameter, giving a rope speed of 5175ft. per minute, and the driving is direct from the fly-wheel to the line shafts; those in the mule-rooms making 300 revolutions per minute. The whole of this work, with pipe connections to the boilers, was made by Messrs. Pollitt and Wigzell, Sowerby Bridge. The boilers, six in number, made by the Oldham Boiler Company, are 8ft. diameter by 30ft. long, with 110 lb. working pressure, and four of them, fitted with McPhail and Simpson's dry steam generators, are placed in a house alongside the engine house, with a Green's economiser, containing 480 pipes.

From the cotton mills the party proceeded to the Oldham Corporation Electric Light Works, which, designed by Professor Alex. B. W. Kennedy, were commenced in 1892, completed and inaugurated on 15th March, 1894, and are now in charge of the resident engineer, Mr. S. Wilmot Newington. The streets provided with the electric light are the principal business thoroughfares of the town, and the plant is sufficient for the simultaneous lighting of about 2500 incandescent lamps of eight candle-power each, ample reserve being provided in case of any machines requiring repair.

As the area to be supplied is small, and there are many hours during which the amount of lighting required is very limited, a low-tension system of the simplest possible kind has been adopted—namely, a two-wire system, in which the current is distributed at 105 volts. The mains are bare copper, carried upon stoneware insulators in concrete troughs, or conduits under the footpaths. Where roadways are crossed, or where there is not room for a concrete conduit, the mains are laid as insulated cable, carried in cast iron pipes or casings. The conduits are so arranged that fresh copper can be pulled into them without opening up the roads or footways beyond lifting the covers of the manholes. The system of supply is arranged throughout so that it is possible at any future time to change it into a three-wire system with a minimum of alteration, and without pulling up the footpaths or roadways. The batteries are provided partly for a reserve, but mainly for the purpose of supplying current during the period of minimum demand, which in Oldham is often long. They are charged by the dynamos during the hours when the latter have no work for supplying current to the circuit. By allowing them afterwards to discharge, the whole station can be shut down at night, and often in the morning also, so as to economise expenditure in wages and fuel. It is also intended that the waste gases from the Corporation destructor on adjoining ground shall be utilised under one of the two boilers, thereby saving a certain amount of fuel.

The next visit was to the Hartford ironworks of Messrs. Platt Brothers and Co., the party receiving a very considerable accession by a number of members who came on during the afternoon by train from Manchester. These works, which were founded in 1821 by Mr. Henry Platt, have now attained a magnitude far above that of any other textile machine works in the world, and their inspection was looked forward to with no little interest. Before, however, going through the works, the party

"The Engineer"
Swain Eng

were invited by Messrs. Platt Brothers to luncheon in the new dining-rooms adjoining, which have only just been completed for the accommodation of the workmen and boys who live out of town—the visit of the Institution of Mechanical Engineers being, in fact, seized as a suitable opportunity for inaugurating the opening. This new dining-room is 200ft. long by 60ft. wide, and provides accommodation for upwards of 1000 hands, whilst it will seat comfortably about 1200 people. It is lofty, excellently lighted and amply provided with lavatories, &c. After luncheon, Professor Kennedy, the President of the Institution, briefly proposed the health of their host, Mr. S. Platt, who, in responding, said he was pleased to see the members of the Institution of Mechanical Engineers present that day, and to show them the whole of the works, which were open for their inspection. Referring to the aspects of industrial operations such as their own, there were, he said, certainly times in which they were only carried out under great difficulty, and it was for them to be constantly on the watch as to how to meet these difficulties, and to battle with the ever increasing competition of the world. The new dining-room in which they were assembled, and the opening of which the members of that Institution were practically inaugurating, was, as they had already been informed, erected for the special accommodation of their workmen, and he hoped they were at the same time also inaugurating new relations between themselves and their workpeople.

Of course the time at the disposal of the members only enabled them to make a very partial inspection of one portion of these extensive works. They are fifty-five acres in extent, exclusive of the collieries, and comprise the old works, the new works, the Werneth spindle works, wood sawing mill, and forge and brick works, which are united by lines of railway connected with the Lancashire and Yorkshire Railway. Several locomotives are kept constantly at work during the whole day conveying the trucks of raw material between the stations and the various parts of the works, and also taking out the trains of finished machinery. The old works are situated about two miles from the new works, and are quite independent in their operations, having iron foundry, smiths' shops, special tool-making and millwrights' departments, turning, planing, fitting, and erecting rooms, &c., where all the machines for ginning, and for opening and carding cotton, wool, and worsted, are made and packed for conveyance to the station. The new works, which were gone through by the party, are the largest of all, and have also their own steel, iron and brass foundries, smiths' shops, turning, planing, fitting, and erecting rooms, as well as special tool-making and millwrights' shops, where machines for combing, drawing, preparing, spinning both by mules and ring frames, warping, sizing, and weaving cotton, woollen, worsted and silk waste are constructed, and delivered on trucks to the railway. The Werneth spindle mills are in close proximity to the new works, and all the spindles and flyers for spinning frames, as well as the spindles for ring-spinning frames, and for self-acting mules, twiners, and doubling frames, are made here, together with tin rollers and copper cylinders for the various machines. File-cutting is also an important branch of this establishment. The sawmill, capable of turning out 350,000 cubic feet of timber per annum, and timber yard cover a space of eight acres, and are amply provided with lines of rails and travelling cranes for the quick conveyance of timber baulks to the sawmill and elsewhere. There are numerous vertical and circular saws at work reducing the largest logs of wood to planks of various widths and thicknesses. The machines, which are nearly all of the firm's own make, are driven by a compound horizontal steam engine of 400-indicated horse power. In connection with the sawmill there are rooms in which all the operations of wood turning, planing and joinering are carried on by means of the most improved appliances. There are also steam drying stoves, built upon the fire-proof system, where the timber is dried before using, as well as large steers for seasoning the timber planks. The sawmill and timber yard are lighted by electricity by means of sixteen Brush electric lamps of 2000 candle power each. Adjoining the saw mill is a building devoted to the manufacture of the fluted iron rollers required in textile machinery. This building is in shed form, about 315ft. long by 100ft. wide, with a cellar under a portion of it. In the cellar the rollers are cut into the required lengths, and thence are taken into the shed above, where they are turned and fluted by means of lathes and fluting machines. In the brick works, which have been built to utilise the clay found on the site of the place, an automatic brick-making machine, capable of turning out about thirty-four bricks a minute, by what is known as the "semi-dry" process, which produces the smoothest and best surface bricks made by the trade, attracted considerable attention. The clay is passed through air-drying tubes, breakers, pulverisers, and disintegrators, from which it issues in fine dust, and is then pressed into semi-dried bricks ready for placing in the kilns, of which there are six, each capable of holding about 70,000 bricks. Fire-bricks are also made here from material procured from the firm's own mines. It may be added that extensive collieries have been acquired with a view to secure an ample supply of coal and coke of undoubted quality, for the requirements of the works. These include the Moston colliery, situated about half-way between Oldham and Manchester, the seams yielding excellent house-fire coal as well as furnace coal; the Tunshill and Butterworth Hall collieries at Milnrow, and the Jubilee colliery at Crompton, about four miles from Oldham, which raise the mountain mine coal of very pure quality, and smithy coal, coke, and foundry coke are here produced, containing a minimum of sulphur. The plant includes coal-washing apparatus, 108 coke ovens, and coal crushing machinery, making coal dust for foundry purposes. Situate also at Crompton are the Brushes, Clough Sand, and Fireclay Works, which supply the forge and foundries with sand of various kinds, especially ganister, obtained of excellent quality. About 1000 men in all are employed at the collieries, and the total number of hands employed by the firm exceeds 10,000.

The alternative excursion to Bury and Rochdale on Thursday, the 2nd inst., was well patronised and greatly enjoyed by the members. At Bury the party was met by Mr. Henry Webb, and conducted over the Peel Mills. These mills are among the best examples of modern mills for spinning American cotton. The machinery, which is of the latest and most improved kind, was supplied by Messrs. Platt Brothers, of Oldham, and the blowing-rooms were fitted by Messrs. Lord Brothers, of Todmorden. They have their own railway sidings, and are fireproof throughout, fitted with automatic sprinklers, and lighted by electricity, which is generated by "Castle" dynamos made by Messrs. J. H. Holmes and Co. The dynamos are in a separate house, and are driven by two compound high-speed non-condensing engines, each 90-horse power, working at 200 lb. pressure. In these engines slide-bars are dispensed with; the upper ends of the links coupling the pistons to the triangular connecting-rods are provided with ball joints, and these are adjustable from outside the cylinders; they permit the pistons to revolve, so that all grooving of the cylinders, pistons, and trunks is avoided. No. 2 mill has a quadruple-expansion vertical engine of 1600-horse power, provided with Corliss valves throughout. The steam pressure is 200 lb. per square inch, generated in four Lancashire boilers, 28ft. long and 8ft. diameter, made of steel and tested to 360 lb. pressure. The cylinders are arranged in pairs on each side of the fly-wheel or rope drum, the high-pressure and first intermediate cylinders on one side, and the second intermediate and low-pressure on the other. The crossheads of each pair are connected by a pair of links and a Fleming and Ferguson triangular connecting-rod to a single crank; the two cranks of the engine are opposite to each other, so that the weights of the two sets of reciprocating parts are balanced. The action of this form of connecting-rod is such that there is no dead centre. The cylinders are 18in., 26in., 37in., and 54in. diameter, with 4½ft. stroke, and the engines make eighty revolutions a minute. There are two air pumps, 26in. diameter and 15in. stroke. The rope drum is 21ft. diameter, with 36 grooves, the diameter of the ropes being 1⅜in., and their velocity 5280ft. a minute. No. 1 mill has a side-by-side compound engine of 1300-horse power, working at 95 lb. pressure per square inch. The cylinders are 32in. and 56in. diameter by 6ft. stroke. The air pump is 39in. diameter by 31in. stroke. The rope pulley is 32ft. diameter, weighs 75 tons, and is grooved for thirty 1⅜in. ropes. The high-pressure cylinder is fitted with Corliss valves, and the low-pressure with slide-valves. Both engines were made by Messrs. John Musgrave and Sons, of Bolton. Through the courtesy of Mr. Webb we are enabled to give the result of a week's working on both of the mill engines, the compound horizontal engine indicating 1160-horse power, driving 67,000 spindles, half twist and half weft, on a fuel consumption of 69¾ tons, equivalent to 2·3 lb. of coal per horse-power per hour. In the same period the quadruple engines consumed 69½ tons of coal to drive 100,000 spindles, half twist and half weft, indicating 1400-horse power, giving a coal consumption equal to rather less than 2 lb. of coal per horse-power per hour. It should be stated that hand firing is employed exclusively at these mills.

From the Peel Mills the party divided into two sections, one visiting Messrs. Adam Ashworth and Sons, and the other Messrs. Lucas and Co.'s felt hat works, where the routine production of felt hats was shown. The two sections then united again and took train for Rochdale, where after being hospitably entertained at luncheon by Messrs. Thomas Robinson and Son, the party was split up and conducted over the works.

These works are situated close to the Lancashire and Yorkshire Railway, and cover an area of about seven acres, employing about 1200 men. Lying nearest to the railway are the saw mill and joinery works, where almost every kind of woodwork is produced direct from the log. The timber in the log is first sawn on a large horizontal double-saw frame, with two saws having a horizontal reciprocating motion; they are driven at a high speed from a double-throw crank, whose centres are opposite, so that the motion of the one saw balances that of the other. The saws cut in both directions of their stroke, so that the feed of timber is continuous. Alongside is a vertical log saw frame, arranged to work with a number of saws at once for sawing up small logs and deals. There are also various kinds of self-feeding circular saws; also planing machines, mortising and tenoning machines, &c. In addition to joinery, this department is largely devoted to the manufacture of flour-milling machinery, principally dressing, such as semolina purifiers, sieves, bran dusters, &c., which follow the work of the roller mills in the conversion of grain into flour.

The works are so arranged that the raw material enters by the main line, and is discharged from the wagons direct at the foundry and smithy, from which during the course of manufacture it passes in direct circulation to the fitting shops and packing department. The iron-foundry is a large building 317ft. long by 94ft. wide, built in two bays. A line of columns passes down the centre, supporting the roof and crane road. Three overhead steam travelling cranes traverse the whole length of the building, each capable of lifting a load of 10 tons. A number of machines are at work here for moulding pulleys and wheels and from plate patterns. The smithy is a similar building to the foundry, being lofty and spacious. It is 150ft. long by 45ft. wide, containing fifteen fires, and is fitted with steam hammers, forging machines, and tools for special work in cutter making. The lower end of the fitting shop is devoted to the construction of wood-working machinery, and the upper end to roller mills for flour milling and to steam engines. The total length of the fitting shop is 537ft., and its width 103ft. In addition to many special turning, grooving, and milling machines, there is a balancing apparatus, by means of which pulleys and cutter blocks are accurately balanced for the speed they are intended to run at. An overhead travelling crane driven by ropes works over the engine fitting shop, and is capable of lifting 15 tons. The machinery in this department is driven by a horizontal compound tandem engine of 40-horse power, having an ordinary slide valve with an arrangement whereby the cut-off is regulated by the governor according to the load.

Amongst the most interesting plant which was inspected in process of construction, we may mention a fine machine for planing, mortising and boring huge balks of greenheart timber for making lock gates. This machine is capable of taking material 60ft. long, and is being made for the Mersey Docks and Harbour Board. We hope to place an illustrated description of it before our readers in an early issue.

On Friday one of the principal excursions was to the Lancashire Watch Works, at Prescot, which practically occupied a numerous party the whole day. They were accompanied by Professor Kennedy, the President of the Institution. We have previously given some description of these works in connection with their formal opening about a couple of years back. The entire scheme for the factory has not yet been carried out, but when completed it will occupy a rectangular plot of ground of about 11½ acres. The front building will be 440ft. long by 28ft. wide, and four storeys high, the central portion forming the administrative department. Behind the whole length of this building, and separated from it by areas for light, will be the main works corridor 20ft. wide, from which the different workshops will be entered. The latter will be placed with their lengths at right angles to the corridor, and are intended to be seven in number, the outer being three storeys and the inner one storey high. The rear of all the workshops is intended to be connected together by a rope-race, for the transmission of power by cotton ropes, the areas between the workshops being approached by archways. The steam engines, boilers, and electric lighting plant are intended to be in the centre of this rope-race. The buildings already completed consist of one of the three-storey outer workshops and two of the one-storey inner shops, occupying a space of 300ft. by 260ft., and with a total floor area of 59,325 square feet. The dimensions of the three-storey workshop are 300ft. in length and 28ft. in width, and the large one-storey warehouse, a portion of which is temporarily divided off for the present engine and boiler and other purposes, is 336ft. long by 100ft. wide, whilst the smaller one-storey workshop is 256ft. long and 45ft. wide. The present offices are contained in what will ultimately be the main works corridor. The three storeys give space for the employment of 700 workmen, whilst the factory as it at present stands provides accommodation for at least 1500 workpeople, and turns out a minimum of 500 complete watches a day. It would be impossible to enter into anything like a detail of the different departments of the works, and the infinite variety of tools, mostly of special design, which are employed in the numerous operations of watchmaking by machinery. The members were occupied close upon four hours in going through the various departments, starting at the drawing-office where they were shown how a watch is designed, then through the tool room, blacksmith's shop, pattern shop, clerical department—where they were shown the system of taking prime cost and material keeping—the engine house, on to the press room, the pinion shop, through the balance rooms, stores, framing shop, gilding room, case room, escapement, jewelling, and motioning room, on to the erecting, dial, and examining rooms, where the trueing and poising of the balances of the completed watches is performed, and the mechanism is finally fitted in the cases and timed. As a general description of the works, it may be stated that the side walls of the shops are constructed of cast iron stanchions, filled in to a height of 3ft. above each floor with brick-work, and over this with glass in wood frames, so that continuous windows are formed the whole length of each side. The ground floors are solid, formed with a layer of ballasting and a layer of Portland cement concrete. The upper floors are fire-proof, with steel girders supported on cast iron columns. The three-storey workshop has an ordinary slated roof, but the one-storey workshops have saw tooth shed roofs with large skylights facing the north. For ventilation Blackman air-propellers are employed, the outlet ventilators being on the induced current principle, preventing down draught, and the steam generated in a boiler 30ft. by 8ft. is used for heating the buildings throughout. The motive power is provided by a locomotive type boiler, working at 140 lb. pressure, and supplying steam to a Marshall compound engine capable of developing 80-horse power, from which the various shafts are driven by cotton ropes working in iron-grooved pulleys. The shafting is of steel throughout, and the belt pulleys, which are made in halves, will fit on it anywhere. The work benches have wood tops, 2½ft. wide, carried on cast iron standards, which are secured to the floor boards and joists, the total area of bench tops being 14,480 square feet. In the smaller one-storey shop, which is used for making tools, there are a joiners' shop and a smithy partitioned off at one end, and there is accommodation for about one hundred mechanics, whilst the larger one-storey shop is employed in the making of watch movements, there being accommodation for about six hundred workpeople. In the three-storey workshop the first-floor contains the flat steel and stem-winding departments; the second floor is used for jewellery, gilding, escapement, and balance making; and the third floor for assembling room, dial, and band making.

The inspection of the works having been completed the party were entertained at the King's Arms Hotel by Mr. T. P. Hewitt, managing director of the company, and before separating,

Professor Kennedy said, as one of the oldest members of the Institution of Mechanical Engineers, he desired, on behalf of his fellow visitors, to say that to all of them that visit had been the most pleasurable and instructive they had ever had. At various times they had visited many engineering and mechanical works, but during all their excursions they had never met with so high a development of mechanics, nor seen a factory where there was so splendid an organisation, or where the employés worked under more favourable conditions of good light, atmosphere, and sanitation, as at the Prescot Watch Factory, where he thought these arrangements were pretty nearly perfect. He also desired to thank Messrs. Hewitt for the kind and hospitable manner in which he and his fellow members had been treated.

Mr. T. P. Hewitt, in responding, said that when their secretary—Mr. Bache—wrote that so distinguished a body as the Institution of Mechanical Engineers were coming into the neighbourhood, and more especially as his brother was to read a paper on screw-making before them, he ventured to think it would please the members to come and see what was being done by mechanical aid at the watch factory. He was therefore extremely pleased to hear that they had been able to teach them something new, and certainly, to his mind, the operations required for making machine-made watches was one of the highest forms of mechanics. Many of the visitors had expressed to him the pleasure they had experienced, but the greatest source of gratification to him was to hear them admit that they had learnt something which might be of use to them hereafter.

The members who chose the alternative excursion to Bolton and Horwich on Friday were divided into two parties. Party "A," which was limited to ninety, paid a visit, first to the fine spinning cotton mills of the North End Spinning Company, under the guidance of Mr. Herbert Mather and Mr. H. S. Forrest, and next to the works of Messrs. Dobson and Barlow, under the guidance of Mr. Benjamin A. Dobson.

These works occupy over twelve acres, and although large additions have been made to the original buildings, by great care the modern requirements have been maintained, and, with the exception of the style of buildings, no disadvantage exists. In a preparing and spinning-machine manufactory the variety of trades is enormous. Those under direct supervision in this establishment number no fewer than thirty-two. The foundries are extensive; the heavy work is served by power cranes, the lighter by metal trams. There are five cupolas, capable of melting from 90 to 100 tons of castings per day. Two of the cupolas, on account of their proximity to the wood sheds, have the uptake turned over into a downtake, which is conveyed to the chimney by a flue, thus avoiding the dispersion of sparks in the air. The heated air in passing raises the temperature of the blast supplied to the cupolas, as the blast-pipe passes through the hot-air flue. The cupolas are charged by power hoists. The chimney is 366½ft. high, and was for long the largest stack in the world; even now it has only two or three competitors. It was constructed for a chemical works formerly upon the ground, which has been absorbed by the machine works. There is a small steel foundry; also a brass foundry, and softening, annealing, and hardening furnaces. The machinery made in this establishment is principally for cotton spinning and doubling, although silk, wool, and other fibres are also dealt with. Thus the machines may be divided into those for ginning, scutching, carding, combing, drawing and preparing, ring and mule spinning, ring and mule doubling, winding frames, gassing frames, and bundling presses; in fact, all the requirements of a cotton mill. The fitting-rooms are arranged to suit this category, and there is one general preparation in the way of planing, milling, polishing, and turning. Many of the milling and turning machines are made to serve a special purpose, and not a few of them show great ingenuity.

Bolt and nut turning, automatic screw-making, automatic wheel-cutting machines, multiple milling machines, are of various kinds and considerable in number. Subdivision of labour is the secret of the existence of the machine trade; without it competition with foreign makers would be impossible. Therefore it is that the machine tools in the works have all been designed with a view to economy of production. The work required is of the most exact character; in several cases pieces of 50in. diameter of thin cast iron have to be turned to the 1000th part of an inch. The wood-working department is also extensive. Here, again, the object sought for has been to reduce the cost of labour. The multiplicity of pieces in a business of this description is almost incredible, the number of articles dealt with amounting to hundreds of thousands per week. The packing department for the large foreign trade is of great importance. Each framing and article of any weight is securely fastened by stays, which in turn are nailed to the case. About 1000 cases of machinery per week are despatched to all parts of the world.

The boilers employed are of the Lancashire type, supplied with Galloway tubes, and furnished with mechanical stokers on the spreading system. Some of the engines are old; but there are three or four new ones, including two high-speed engines, one running at 240 revolutions and the other at 140. The bevel and spur wheels in connection with the driving gear have been abolished by degrees in favour of ropes or straps. A large portion of the works is lighted by the inverted arc lamp reflected from a whitewashed ceiling—"Proceedings," 1893, page 396. In the dynamo-room are different kinds of dynamo and switch arrangements. Electric welding is also a special feature in these works. In the third storey of the building facing the principal entrance gates is an experimental room, where are samples in working order of the principal types of cotton spinning machinery constructed. This room affords extremely interesting explanations of the principles of such machinery.

The members of party "B" first made their way to Messrs. Hick, Hargreaves, and Co.'s works. The Soho Works were erected in 1832 as a general engineering establishment, the earlier products being stationary steam engines, boilers, mill gearing, hydraulic machinery, water wheels, marine engines, and locomotives; of the last a large number were made here for the Liverpool and Manchester and other early railways. This firm was the first to introduce the Corliss engine into this country about 1865, and they have been closely identified with it ever since. Over 1100 of these engines have been built of all sizes from 40 to 10,000 indicated horse-power, simple, compound, and triple-expansion, adapted for all pressures up to 200 lb. per square inch. Steel boilers were first made at the Soho Works in 1863; and their present capacity, including the Phœnix Works, is about 150 boilers a year. The boilers are mostly of the Lancashire type, but upwards of 200 torpedo-boat boilers of the locomotive type have been made; some of the most recent of these have each 2400 square feet of heating surface, and whilst weighing only 16 tons have given 1750 indicated horse-power on the trial trip. Mill gearing in all its branches is also a speciality; some large fly-wheels for rope driving have been made, a recent example being 32ft. diameter, grooved for 56 ropes weighing 128 tons, and to transmit 3000 indicated horse-power. Turbines and hydraulic machinery are also largely manufactured. The works have been extended from time to time to suit the growing requirements of the business, and they now cover seven acres, and give employment to about 1000 workmen. They are divided into nine departments, namely two pattern shops, brass foundry, three moulding shops, smiths' shop, heavy machine shop, light machine shop, with fitting and erecting shop, millwrights' turning shop, and millwrights' erecting shop. The tools are modern, many being of a special character to suit the work, and there are ten rope-power travelling cranes from 15 to 40 tons capacity. The motive power consists of five Lancashire boilers, 7ft. diameter by 30ft. long, working at a pressure of 70 lb. per square inch; and six engines, giving altogether about 450 indicated horse-power. The works are advantageously situated, being traversed by sidings from the London and North-Western Railway. The Phœnix Boiler Works were purchased in 1891, the boiler department at the Soho Works having become inadequate to meet the demands upon it. It is contemplated to remove all the boiler-making plant to these works, and to utilise for other purposes the space now occupied by the old boiler shop at the Soho Works.

From Messrs. Hick, Hargreaves' works the party next proceeded to Messrs. John Musgrave and Sons, Globe Iron Works. This firm of engineers, boiler makers, and millwrights was established in 1839 by John Musgrave, and has been worked and carried on by his sons and grandsons up to the present time. At first the works employed only about fifteen men; but the growth of the business has necessitated continual alterations and additions until the works now occupy over eight acres, almost entirely covered by buildings, including three foundries, with complete accessories of pattern shops, dressing shed, store rooms, &c. There are four shops devoted to engine work, and four others for mill-gearing, besides large engine-erecting shops, and extensive boiler-works, smiths' shops, and all the numerous adjuncts, providing employment for about 1000 men. The special work produced comprises quadruple, triple, and compound engines, with triangular connecting-rods, and having no dead centres; also quick-speed engines on this principle, designed especially for electric machinery; Musgrave's barring engine and Corliss valve-gear, Crompton's metallic packings for piston-rod glands, Buckley's piston-rod support, Tabor indicator, &c. The engines are constructed with a special view to high-class finish, steady turning, and economical running; they are driving a large number of the most successful cotton-spinning and weaving mills in this country, India, Russia, Germany, and Japan; and examples of the work here produced have gone into nearly every part of the world.

The two parties afterwards united to visit the Lancashire and Yorkshire Railway Locomotive works at Horwich.

These works, of which the building was commenced in 1886, are situated between the Chorley New Road, Horwich, and Red Moss, and are about one mile distant in an easterly direction from Blackrod Station upon the main line between Manchester and Fleetwood. The land enclosed for the works comprises 85 acres, and lies north-west and south-east. The covered area of workshops is 15 acres. They comprise offices, general stores with gallery, boiler shops, smithy, forge, foundries, tin and copper shops, machine shops, erecting and repairing shops, &c. The boiler shop is fitted with the necessary cranes, portable and fixed riveting machines, multiple drilling machines, pneumatic fullering tools, quadruple stay-tapping, and plate-edge planing machines. The boiler shop and smithy contain hydraulic flanging press; and in the forge are a plate-straightening machine, rolling, tire, and merchant mill engines, tire and merchant mills, and a 30-ton Ramsbottom duplex hammer. In the steel foundry are melters, core-drying furnaces, and a wagon-wheel moulding-machine, &c.; and the iron-foundry is adapted for light and heavy castings. The steel dressing shop contains annealing furnaces, and is used for dressing steel castings. The wagon-wheel shop comprises lathes for boring and turning wagon wheels; one set of lathes rough the work, and the remainder finish it. Bolt machines, drop stamps, and nail-making machines are in the bolt shop of the smithy. The erecting and repairing shop is provided with 30-ton cranes, portable hydraulic riveters, flexible shaft-drilling machine, and the necessary complement of tools. Steel castings are largely used in the manufacture of the locomotives. The tender shop is for the making and fitting up of tenders; and the paint shop contains the necessary paint-grinding and mixing machinery and stores. In the chain-making and testing shop is a 100-ton chain-testing machine, together with the necessary chain makers' fires, &c. To facilitate the carriage of material from the stores, and of work to the various shops, a system of 18in. gauge tramway is laid to the extent of 7¼ miles, the haulage being performed by small locomotives. The shops and offices are fitted with both arc and incandescent electric lights. The fitting shop is lighted with inverted arc lamps, and each department of the works is also in telephonic communication with the offices. Owing to want of time the members were unable to make a complete survey of the works.

## GOODS ENGINE—MANCHESTER, SHEFFIELD, AND LINCOLNSHIRE RAILWAY.

In The Engineer for April 13th and 16th we illustrated and described certain express engines, described by Mr. J. Parker before he resigned his position as locomotive superintendent on the Manchester, Sheffield, and Lincolnshire Railway. We now illustrate one of several powerful tank engines, which have been at work for some time in conducting the goods traffic of the line. The following table gives all the principal dimensions:—

| | | | |
|---|---|---|---|
| Cylinders—diameter | 1ft. 6½in. | | |
| ,, stroke | 2ft. 2in. | | |
| Steam ports | 1⅝in. × 1ft. 2½in. | | |
| Exhaust ports | 3¼in. × 1ft. 2½in. | | |
| Lap of valves—outside | 1in. | | |
| ,, inside | 1/16in. | | |
| Maximum travel of valves | 4 7/16in. | | |
| Lead in full gear | 7/32in. | | |
| ,, in mid gear | ¼in. | | |
| Throw of excentrics | 5¾in. | | |
| Diameter of sheaves | 1ft. 5in. | | |
| ,, piston-rods | 3in. | | |
| Centre to centre of cylinders | 2ft. | | |
| ,, valve spindles | 2ft. | | |
| ,, expansion links | 5¼in. | | |
| Crank pins, connecting-rod—diameter | 8½in. × 4in. | | |
| Coupling-rod pins—leading and trailing, diameter | 3½in. × 4¾in. | | |
| ,, ,, driving—diameter | 4in. × 4¾in. | | |
| Wheels (cast steel centres):— | | | |
| Coupled—diameter | 5ft. 1in. | | |
| Radial ,, | 3ft. 6in. | | |
| Tires | 5½in. wide × 3in. | | |
| Axles (steel):— | | | |
| Coupled: Wheel seat—diameter | 8¾in. × 7 3/16in. | | |
| Journals ,, | 8in. × 9in. | | |
| Centre to centre of journals | 3ft. 9½in. | | |
| Radial: Wheel seat—diameter | 8¼in. × 6⅞in. | | |
| Journals ,, | 7in. × 11in. | | |
| Centre to centre of journals | 3ft. 7½in. | | |
| Frames (steel):— | | | |
| Thickness | 1 1/16in. | | |
| Distance between, front end | 4ft. 2in. | | |
| ,, ,, hind end | 3ft. 10in. | | |
| From back of buffer plate to centre of leading axle | 5ft. 5⅜in. | | |
| From centre of leading axle to centre of driving axle | 7ft. 11in. | | |
| ,, ,, driving ,, ,, trailing ,, | 8ft. 7in. | | |
| ,, ,, trailing ,, ,, radial ,, | 6ft. | | |
| ,, ,, radial ,, hind buffer plate | 5ft. 3in. | | |
| Total length of frame plate | 33ft. 2⅜in. | | |
| Boiler (steel):— | | | |
| Mean diameter of barrel outside | 4ft. 3in. | | |
| Length of barrel | 10ft. 8in. | | |
| Height of centre line from rail | 7ft. 4¼in. | | |
| Barrel plates | ½in. | | |
| Smoke-box tube plate | 1in. thick. | | |
| Fire-box shell, "Belpaire" form (steel)—width at bottom outside | 4ft. 1in. | | |
| Fire-box shell—length at bottom outside | 6ft. | | |
| Steam pressure | 160 lb. per sq. in. | | |
| 233 tubes, copper, 1¾in. outside diameter, 11 and 13 | B.W.G. | | |
| Length between tube plates | 11ft. ⅝in. | | |
| Saddle plate | ⅝in. | | |
| Back plate | 17/32in. | | |
| Crown and side plate | ½in. | | |
| Fire-box (copper)—Length at bottom inside | 5ft. 4⅝in. | | |
| Width | 3ft. 6in. | | |
| Mean depth | 5ft. 3½in. | | |
| Top of box to inside of shell | 1ft. 5⅞in. | | |
| Tube plate | 1in. thick. | | |
| Below tubes | ⅝in. | | |
| Back plate | ⅝in. | | |
| Crown and side | ½in. | | |
| Heating surface:— | | | |
| Tubes | 1179 sq. ft. | | |
| Fire-box | 99 ,, | | |
| Total | 1278 ,, | | |
| Grate area | 18·85 sq. ft. | | |
| Ratio of grate area to heating surface | 1 : 67·798 | | |
| Smallest diameter of chimney | 1ft. 2in. | | |
| Diameter of blast pipe nozzle | 5in. | | |
| Weights in working order:— | Tons | cwt. | qr. |
| Leading | 15 | 4 | 0 |
| Driving | 16 | 3 | 3 |
| Trailing | 14 | 18 | 0 |
| Radial | 13 | 13 | 0 |
| | 59 | 18 | 3 |
| Capacity of water tanks | 1400 gallons. | | |

## THE NEW UNITED STATES CRUISER MINNEAPOLIS.

The steam trials of the new United States cruiser Minneapolis (see p. 131), which came off on the 14th ult., have given great satisfaction to our American cousins, and have earned Messrs. Cramp, of Philadelphia, her builders, a bonus of 400,000 dols., in addition to her contract price, which was 1,690,000 dols., as she attained a speed of 23·05 knots. She is, therefore, one of the very fastest war vessels afloat, and a worthy addition to the fine fleet that is being created on the other side of the Atlantic. The Minneapolis is one of the few cruisers that are provided with triple screw propellers, among the others being the Columbia, the French Dupuy de Lôme, and the German Kaiserin Augusta.

She was launched on August 12th, 1893, and is 412ft. long, with 58ft. beam, and has a displacement of 7350 tons and a horse-power of 21,000, and is known as a "commerce destroyer," or "pirate." She is not, therefore, provided with an armament suitable for engaging even the large cruisers of other nations, her heavy armament consisting only of one 8in. gun and two 6in. and eight 4in. quick-firers. She has in addition a dozen 6-pounders, four 1-pounders, and four Gatling guns, as well as five torpedo-ejectors; but to anything at all powerful in the way of fighting vessels she is intended to show a clean pair of heels. She is protected by a sloping armoured deck 4in. thick at the sides, and has a double bottom minutely subdivided into water-tight compartments. The engines and machinery will be further protected by patent fuel, which will be packed around them to the thickness of 5ft.

With her centre screw only revolving, the Minneapolis can get along at the respectable speed of 10 knots with a very economical expenditure of coal. Of this she is said to carry no less than 2400 tons, and is able to steam 15,000 miles without re-coaling, so that the mischief she would be enabled to inflict on the mercantile marine of an enemy before she was likely to be caught would be almost incalculable. Still, as the French found in the old war with this country, a *guerre de course*, however successful, has never yet to any appreciable extent influenced the issue of a naval campaign.

# THE ELECTRIC LIGHTING OF PORTSMOUTH AND SOUTHSEA.

DURING the last few years the growth of electricity as the illuminant of provincial towns has made rapid strides; indeed, so much has been done by the country municipalities in this direction, that the metropolis would seem to lag behind. It is, however, so much easier to make a brave show in a small town, and to have it talked of far and wide, than in a great city, that the latter, in so far as words and advertisements go, seems to suffer in the comparison. The enthusiasm with which mayors, and aldermen, and town councillors go into the matter in the country is wanting in the City, and the dinners, at which everyone concerned compliments every colleague, are missing where competition is the rule, and mutual admiration most certainly the exception. And yet, though one must incline to smile at the compliments which are passed round—for their very extravagance robs them of sincerity—one must be amused at the presentations which are made with the lively sense of favours to come, and one may enjoy the dinners, these should all be recognised as parts of the scheme, the main purpose of which is to attract the attention of the local householder, and induce him to get his premises wired and become a customer.

As a rule, the local body contemplating the establishment of an electricity supply station sends a committee on a tour of inspection, chiefly to London, when all available stations are examined, and a vast quantity of information is collected, which bears fruit some time later in the complete and unoriginal scheme which is submitted to the council of the town for its approval; oftentimes the worst points of many systems being taken, while the best remain behind.

The Electric Lighting Committee of the Corporation of Portsmouth, unlike all others, has made great departures into original fields; and, though it went far and wide to study what had been done, it did not in the end follow in any previously dug groove, but laid the foundation of its station upon fresh ground, and has distinctly advanced in its own independent way along the road of progress. Like others, it at first followed in well-worn tracks, but unlike others, it had at an early stage the good luck to learn better things, the courage and the power to make a change, and it is thought that the borough will find in the years to come the advantages of the system it has adopted and carried out.

The employment of the high-tension alternating current transformer system was a necessity for the lighting of a borough which includes, with Portsmouth, Southsea, Portsea, and Landport, and which extends over a great mileage. The necessity for this was pointed out by the engineers who were finally employed by the Portsmouth authorities, and through whom the Provisional Order was obtained. The dynamo builders chosen to carry out this part of the work, namely, the Ferranti Company, possess special experience in high-tension work. But to obtain information as to dynamos in the future, one of Mr. Parson's turbo alternators has been put down for comparison, and for special work, beside the Ferranti machines; and in order that the arc lighting along the sea front should be as perfect as possible, the Ferranti Company has further installed rectifiers at the station, for the purposes of commutating the alternations of the current into simple interruptions, and so gain all the advantages of the continuous current system, without its several drawbacks.

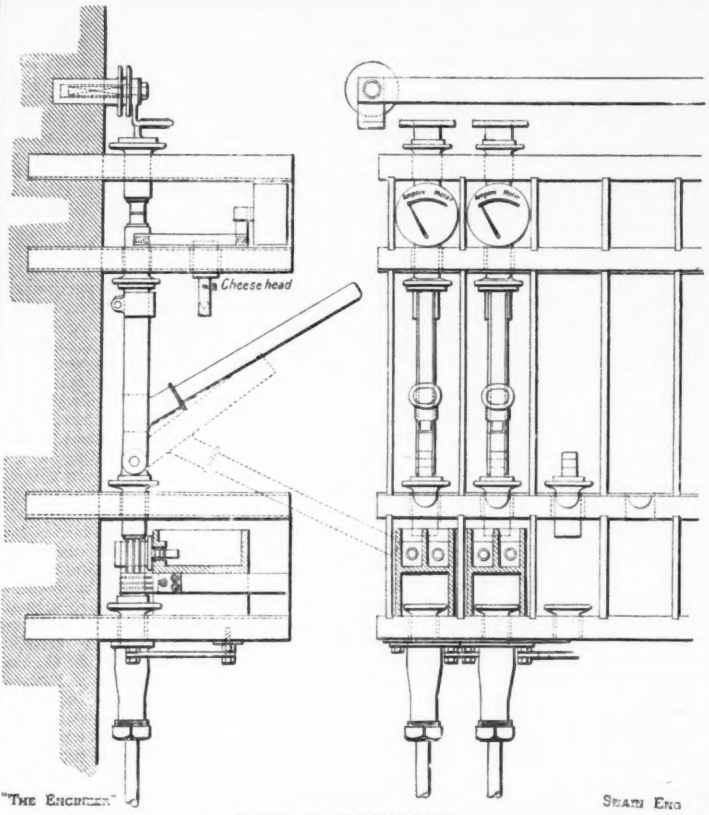
The result is that the arc lighting is remarkable for steadiness, and promises to be so in economy; and it is not surprising to hear that the use of the Ferranti rectifiers is being largely extended in other parts of the country, that the City of London Company has already begun a large installation of these machines for its arc lamps, that the Islington Vestry has ordered them, and that the London Electric Company is also contemplating a departure in the same direction.

The chief points which claim attention in the adoption of the system used at Portsmouth are:—(1) Direct-driven fly-wheel dynamos supplying alternating current at 2000 volts for all purposes. (2) The transformation by means of converters in chambers in the streets, and low-tension distribution from each such chamber, there being no transformers in consumers' houses. (3) The rectification of the alternating current for the arc lamp supply. But though these be the main points in which novelty and progress have been illustrated, a multitude of most important points of detail go to make up the whole.

The generating plant supplied by Messrs. C. A. Parsons and Co., Heaton Works, Newcastle-on-Tyne, at present consists of a Parsons' condensing steam turbine alternator for an output of 150 units. The compound steam turbine is arranged for multiple expansion from the 160 lb. per square inch boiler pressure down to a condenser pressure of ½ lb. absolute, or a range of about 300-fold expansion. The turbine revolves at 3000 revolutions per minute and is coupled direct to a two-pole alternator, giving 75 ampères at 2000 volts, with a periodicity of 50 complete periods per second. To the spindle is coupled the exciter, so that the whole plant is complete in itself and entirely self-contained. It stands on rubber blocks which rest on a concrete foundation without any holding-down bolts whatever. An automatic variable cut-off valve gear and governor, electrically controlled, maintains a constant electro-motive force, and enables the full range of expansion to be maintained at light loads, thus securing exceptional economy of steam on the all-day load. One of these machines, when tested by Professor Alex. B. W. Kennedy, showed a steam consumption of slightly less than 20 lb. per electrical horse-power at full load; at three-quarter load it was only 21 lb., at half load 23 lb., and at quarter load 29 lb. per electrical horse-power. The condenser is of the jet description, but differs somewhat from the usual type.

A separate water pump is placed below the condenser, no injection water proper being admitted to the air pump, which is placed above and is compound. By this arrangement the vacuum obtained is better than is usual with jet condensers, and at the same time the power required to work the pumps is considerably reduced. The pumps are worked from the crossheads of a small tandem compound auxiliary vertical engine, with cylinders 4in. and 7in. diameter and 12in. stroke, supported on girders so as to stand on the footplate of the engine-room above. The exhaust from this engine can be sent either into the chimney or into the condenser. Valves are arranged so that both the steam turbine alternator and the condenser engine can take their steam from either range of steam pipes, and so that the steam turbine alternator can be run high-pressure in case of the injection water failing, or other cause. It has been found that the steam turbine alternator can run satisfactorily in parallel with the other and slow-speed alternators, thus showing the interesting fact of an alternator at 3000 revolutions per minute running in parallel with one at ninety-five revolutions.

In the dynamo room—see page 104—there are two horizontal side-by-side compound condensing steam engines, made by Messrs. Yates and Thom, the fly-wheels, which are utilised as the field magnets of the dynamos, being placed in the middle of the crank-shaft between the two cranks. Each engine will give 320 indicated horse-power, with a boiler pressure of 160 lb. per square inch when running ninety-six revolutions per minute. We have published details of these engines in our last impression. The high-pressure cylinders are 15in. diameter, and the low-pressure cylinders 28in. diameter and 3ft. stroke. All the cylinders are steam-jacketed in the bodies, lagged with planished steel, and fitted with Corliss valves and gear. The high-pressure cylinders are provided with Dobson's patent automatic expansion Corliss valve gear, controlled by the governor, of which Messrs. Yates and Thom are the sole makers for this country, and the low-pressure cylinders with Corliss valve gear with variable expansion adjustable by hand while the engines are running; the steam valves in each case being worked independently of the exhaust valves. The piston-rods are steel 3¼in. diameter, the crank-shaft also, with main journals 9in. diameter and 16in. long, swelled up in the middle to 12in. diameter. The crank-shaft pedestals are cast with the foundation frames, and are fitted with gun-metal steps in four parts, with side wedges and screws for horizontal adjustment. The fly-wheels of both engines are 12ft. 9in. diameter and 1ft. 9½in. wide, made in halves, and prepared round the rim for sixty-four poles, each wheel weighing with bolts, hoops, &c., but exclusive of poles and wiring, about ten tons. The air pump of each engine, which is vertical and single-acting, is placed in a chamber between the cylinders, and is driven by means of a rocking lever attached to the engine crosshead. It is 19in. diameter and 11¼in. stroke, the working barrel being lined with gun-metal and fitted with a gun-metal bucket and rod.



DETAIL OF SWITCH-BOARD

The bucket and delivery valves are of india-rubber on the multiple principle.

The condensing water is supplied to the jet from the Camber, which is a sort of tidal basin or offshoot of Portsmouth Harbour, and which is distant some 250 yards from the condenser. The injection pipe is 14in. in diameter, and the mean level of the water is 18ft. below the condenser; but notwithstanding such severe conditions, a highly efficient vacuum can be maintained. The discharge pipe from the condensers runs along beside the injection pipe and returns the condensing water and condensed steam to the Camber; while, at the same time suitable atmospheric exhaust pipes have been provided for the engines in case of failure of any part of the condensing plant. It is not clear why the engineers have selected jet condensers, as the supply of water is at all times sufficient for surface condensers; and, had the latter been adopted, many advantages would obviously have followed, and all the complication involved in the use of Stanhope, or any other kind of water softeners, would have been rendered unnecessary.

Both engines are massively built, and are provided throughout with indicating gear and efficient means of lubrication, also with brass-mounted oil drippers, neatly polished handrails and pillars round the working parts of the engines, and all other necessary fittings for the proper and satisfactory working of engines of the very highest class.

Special attention may be called to Messrs. Yates and Thom's improved isochronous motion for maintaining the engines at one uniform rate of speed. It is a simple and effective device, and consists of friction-wheels running up and down on a hollow governor spindle as the governor balls rise and fall, with suitable gear for causing the fulcrum supporting the governing lever attached to the lower end of the counterpoise of the governor to rise or fall at the same time, for effecting the necessary compensation for maintaining the governor balls at a constant vertical height.

The steam and exhaust ports of the cylinders have been made of large area, so that the full boiler pressure, as nearly as possible, can be got on to the high-pressure pistons, and also to afford a free and open passage for the exhaust steam. The Corliss valves and gear have been specially designed for giving a quick cut-off, and for obtaining as perfect expansion curves as it is possible to get, with provision for running the steam pressure down in the boilers—the range of cut-off being with this gear from 0 to ¾ of the stroke. Messrs. Yates and Thom have, we understand, fitted this Corliss valve motion to a very large number of engines.

There are five steel Lancashire boilers, each 30ft. long and 7ft. 6in. diameter, with furnace tubes 3ft. diameter, and sufficiently strong for a daily working pressure of 160 lb. per square inch—this type having been selected in preference to that of the water-tube because of its manifest superiority as to simplicity and cost of maintenance and its excellent evaporative powers. The shell plates are $\frac{23}{32}$in. thick, the furnace plates $\frac{17}{32}$in. thick, the end plates $\frac{11}{16}$in. thick, and the cover plates $\frac{23}{32}$in. thick. The shell of each boiler is made in eight parallel rings of plates, the longitudinal seams in the shell being treble riveted, and made with double cover straps having six lines of rivets, the ring seams as well as the end plates being double riveted. The furnace tubes are each made in twelve rings of plates, with eleven flange seam expansion joints. The end plates both at front and back are solid, rolled in one piece, not welded. The front end plates are attached to the cylindrical shell by external steel angle rings 5½in. by 5in. by $\frac{11}{16}$in., and the back end plates to the shell by a flange formed on it by the hydraulic press. Each end plate is stayed to the shell by five gusset stays above the furnace and tubes, and two below at front, and three below at the back, and in addition two strong longitudinal stay bolts from end to end of each boiler. All the rivet holes throughout each boiler are drilled and countersunk on both sides, and the whole of the shell plates, as well as the cover straps, are planed on their four edges. All the end plates, angles, and flue tubes are turned on their edges, and the end plates bored out for furnace and flue tubes. The steel used throughout the boilers is of mild ductile quality, and by the Siemens-Martin process. Each boiler is fitted with a full complement of mountings, with two 6in. junction valves for duplicate ranges of steam pipes. The mountings are made to the Manchester Steam Users' Association's standard, and both boilers and mountings have been made under the Manchester Steam Users' Association's inspection. Each boiler is fitted with Vicars' patent mechanical stokers and smokeless furnaces of the latest improved type, and is fed by one of Vicars' patent fuel conveyors and elevators, with all the necessary dampers, tightening screws, &c., complete; also with the requisite shafting and two small auxiliary engines for driving mechanical stokers and the coal conveyor and elevator, either together or separately.

The fuel economiser is of the Green type, and consists of 288 cast iron heating pipes in three sections of 96 pipes each, the scraper gear being worked by a small electrical motor.

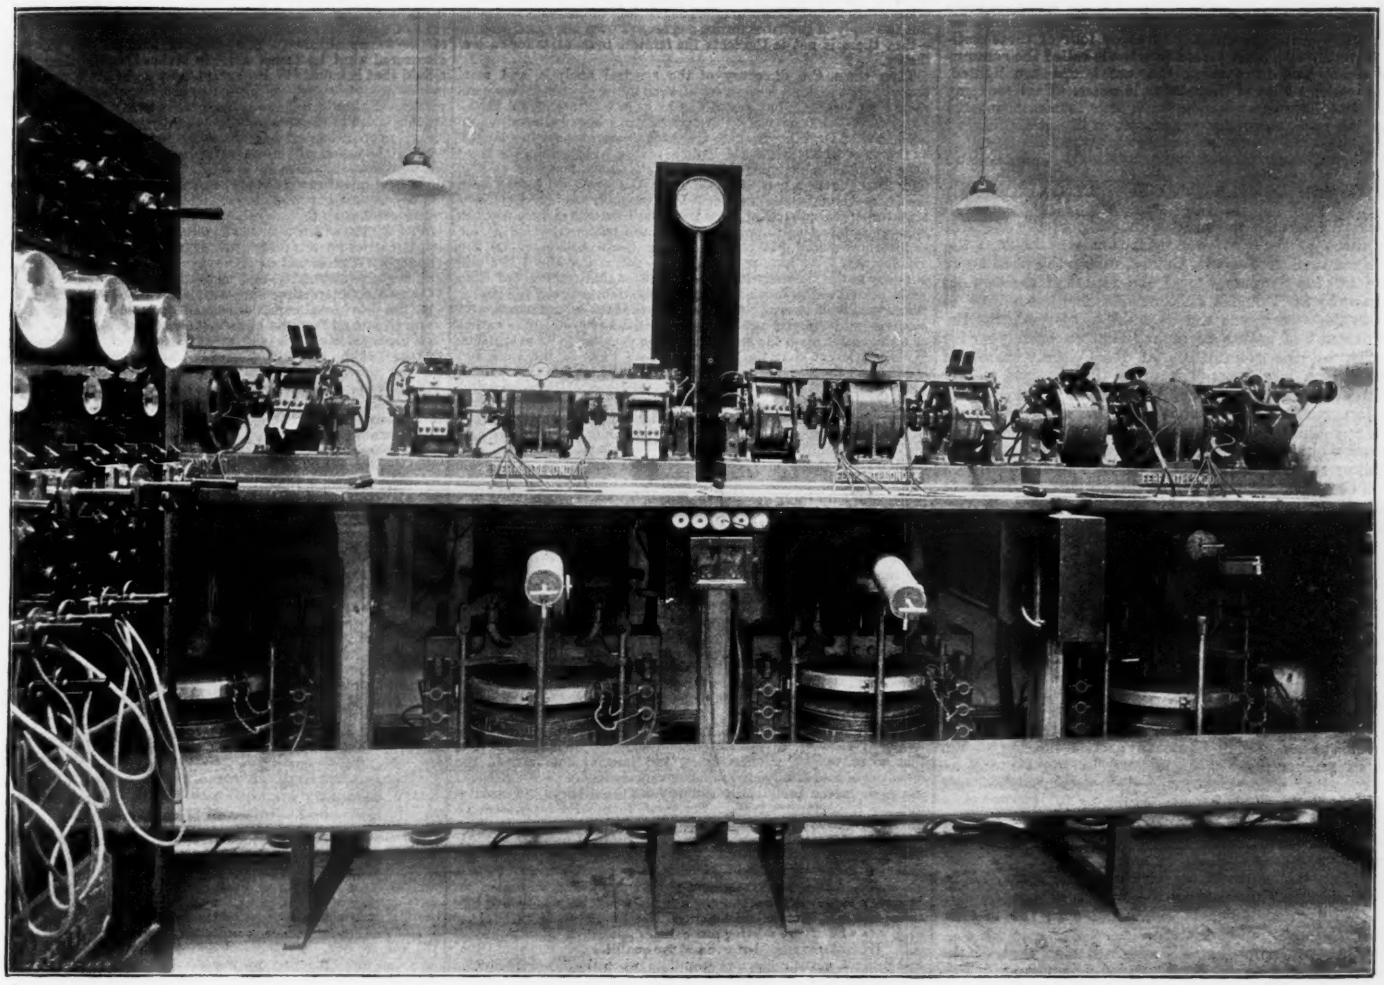
In the pump house are fixed three vertical three-throw single-acting pumps for feeding the boilers, each being capable of delivering 1600 gallons per hour to the boiler, against a pressure of 160 lb. per square inch. The steam cylinder of each pump is 4½in. diameter, 8in. stroke, the crank shaft being connected to the three-throw pump shaft by cast iron double helical spur wheels. The three rams of each pump are of brass, 3½in. diameter and 4½in. stroke, and make about sixty double strokes per minute. The water used in the boilers can be obtained from either of two sources, *i.e.*, the town supply or from a large storage tank erected in the building, and every precaution against breakdown or failure in this direction has been adopted in the way of the duplication of suction, feed, and steam pipes.

One Stanhope water purifier is provided for softening and treating 2000 gallons of exceptionally hard water per hour, with lime mixing, lime settling, mixing tower, softening and clarifying and soda tanks, &c., complete. A cast iron water storage tank is also provided, 28ft. 9in. long, 11ft. wide, and 10ft. deep.

There are two separate main ranges of steam pipes connecting boilers and engines, both being 10in. diameter, and made of lap-welded mild steel with cast steel flanges riveted on the pipes, with the elbows and tee pieces also of cast iron; all the flanges of each main steam range have shallow spigot and faucet joints, with drilled bolt holes, and are bolted together with turned steel bolts ⅞in. diameter pitched about 4in. from centre to centre. Each range of steam pipes is also provided with a mild steel water catcher, of ample size, with internal diaphragm complete, and also drain pipes and an efficient steam trap for effectually draining each range of steam pipes, in addition to which water catchers, with drain pipes and steam traps at the end of each main range are also provided. One of Messrs. Yates and Thom's eight-ton overhead hand power travelling cranes is fixed over the engines and dynamos, the span being 64ft. 9in. from centre to centre of the rails.

Looking at the fly-wheel of the engine, it is at first a little difficult to realise that one is looking at a powerful dynamo, so simple is it in its parts. The magnets of the field are, as we have said, fixed upon the periphery of the wheel. They are each formed of an iron core 9½in. long by 5in. in diameter, the pole pieces or extremities being about 5in. broad, and of the full length of the width of the armature, 17in., and each of these cores, of which there are sixty-four on the fly-wheel, is wound with copper strip, previously prepared in a special machine designed by Mr. Ferranti, the strip being ⅛in. thick and $1\frac{5}{16}$in. wide. It is insulated from the iron core of the magnet by means of vulcanised fibre, and each turn of the copper strip is insulated from its neighbour by fibre or shellaced paper, while the top and bottom of the coil are protected by rings of ebonite or fibre.

# PORTSMOUTH ELECTRIC LIGHT WORKS—FERRANTI RECTIFIERS



The armature frame is round the fly-wheel, and contains the various sections, which are formed of laminated iron, the copper winding of the bobbins, if they may be so-called, being threaded through slot holes through the plates—the necessary insulation being provided by lining tubes of mica having been previously inserted in the slot holes; and the ends of the bobbin coils are protected by gun-metal boxes, which are run up with insulating oil, and make a perfectly tight covering over the bobbins, which are thus protected against any possible mechanical injury. It will be seen from this that as the whole of the high tension part of the machine is therefore entirely covered, and that no part of the framework of the armature is in any way electrically charged when running, the chances of accident to the machine are remote to the last degree, the effects of deterioration of insulation due to atmospheric causes cannot exist, and consequently the life of the dynamo should be long and distinguished.

It makes a very simple machine, and as simplicity in design naturally means ease of overhaul when necessary, such a point will render this type, we are sure, much sought after in the future by the central station engineer. But besides the great advantage of the capability of ready overhaul, he will also possess, when he gets one of these alternators, a machine which, as it has all its vulnerable parts securely covered beyond the reach of dust or damp, of steam leakages or water from a defective roof, or of accident from any falling body, should reduce his anxieties to vanishing point. There is very little really trustworthy data as to the cost in power of rope transmission, though we happen to know that important experiments have recently been carried out by Mr. D'Alton, at Deptford, for the purpose of arriving at the truth, but we are of opinion that these losses have been clearly underestimated in the past, and that, therefore, the gain to Portsmouth in having its dynamos driven directly upon the engine shafts will be shown in the gain in efficiency as between the engine cylinders and the terminals of the dynamos, to be very considerable. The machines already at work in the station are of about 225 unit size, though it is anticipated that when they are required to produce a larger output both engines and dynamos will be found capable of easily carrying a load of 300 units. Provision is made in the station for a considerable increase in number of units of power, and already the foundations have been built for two more machines, which will doubtless be required for the rapidly increasing load of the near future, and the date, we venture to think, is not far distant when the Corporation will be called upon to complete the equipment of the entire station, which will then, it is understood, consist of ten large dynamos, with all necessary engines, boilers, and auxiliaries. The supply commenced with a connection of about 5000 incandescent lamps, of 16-candle power each, and of 100 arc lamps in the public streets; but so rapidly has the demand grown, that the Corporation finds itself quite unable to keep pace with the requirements of the townspeople, and some thousands of lamps are "waiting" for connection, with little prospect of being lighted for many months to come.

The system of transformation suggested by Mr. Ferranti and adopted by the engineers to the Corporation, is by means of street transformers, so placed that each one can be utilised for the supply of all consumers within a radius of 200 yards to 300 yards, the secondary sides of the converters feeding into a low-tension network at 100 volts or a little more, which network starts from each pit and supplies the consumers in the neighbourhood. Each transformer is fitted with suitable switches for the purpose of the alteration of its connections, and such alterations can be made at the will of the engineer in charge, which will alter the point of highest efficiency of the transformer, from full down to any particular point of the load. Thus in winter it might be desirable to work the transformers to give greatest efficiency at three-quarters to full load, while in the summer the best results would no doubt be obtained at, say, quarter load; or, again, it would probably pay the engineer to work them during the day time at such a point that their highest efficiency should be at a very light load, while he could alter his connections at night to a heavier output for best efficiency. Indeed, the changes which an engineer could ring upon these transformers as a whole are many, for it should be borne in mind that the demands of different districts vary greatly—the shopping neighbourhood would require to have its transformers treated in one way, the residential district in another, and those in which public-houses abound differently to others where churches most do flourish. It is proposed to make each transformer alter itself automatically in the future, but for the present the best automatic machine has been found to be a man with a suitable key.

S Z DE FERRANTI LIMTD

SWITCH BOARD

The arc lighting of the public streets and of the sea front was probably the most difficult problem which Messrs. Kincaid, Waller, and Manville, the engineers, and Professor Garnett were called upon to solve, and they can be congratulated upon no point more heartily than upon their success in this. The total number of arc lamp standards erected is just over the hundred, all of which are fitted with arc lamps of the double carbon type, made under the Brockie-Pell patents, and a large number of the standards are further provided each with a pair of 32-candle power incandescent lamps, which serve to provide sufficient lighting during the hours between midnight, when the arc lamps are switched out, and dawn, when the incandescents are in turn put out by an attendant. The incandescent lamps are, of course, provided with the necessary current from the nearest street transformer, the arc lamps having a distinct set of mains of their own from the commutator room of the central station. When the question of the arc lighting was being considered by the engineers, Mr. Ferranti had just completed some highly satisfactory work with his newly-designed motor commutator, or, as he prefers to call it, rectifier, at Faraday House; and when he showed it to the engineers they saw its great advantages, and after a lengthy investigation, adopted it for use at Portsmouth. It obviated the necessity of putting down a separate engine and dynamo for the arc lighting, gave them all the gain of additional steady long hour load upon the main dynamos, and great efficiency in plant use, for the dynamo and rectifier together, as against a separate arc light dynamo with its separate engine, steam pipes, &c., could not fail to show a high degree of economy in capital outlay, in space, and in steam, oil, and other stores, as well as in up-keep and attention, all of which means money. The rectifier consists of a motor, which is synchronous and self-starting, affixed to the middle of a short length of shaft, at either end of which is a commutator, the alternate sections of which are joined together in parallel, and each of these two groups of sections are joined in series to the similar sections of the commutator at the other end of the shaft. Three or four of these rectifiers have already been placed in what is called the commutator room, and from them the arc lamps are lighted, generally about forty of them being in series. Each arc lamp circuit has its own switch, and the little commutator room has all the appearance of a central station in miniature.

## THE BRITISH ASSOCIATION AT OXFORD.

Last Wednesday morning a meeting of the General Committee of the British Association was held in the new Examination Schools, Oxford, under the presidency of Dr. Burdon Sanderson, and the report of the Council was read by Sir Douglas Galton. Among the points set forth in the report was the desirability of rendering the total amount of grants of money allotted each year for research by the committees of the Association more uniform, and less dependent upon the receipts at any particular meeting of the Association. The Council therefore recommended "that it is not advisable to lay down any definite rules as to the amount to be expended in grants, but that, as far as circumstances permit, the following regulations should be adhered to:—(1) That £1000 be at present regarded as the normal annual grant in aid of research. (2) That this sum be annually granted, unless the estimated floating balance in the hands of the treasurer at the end of the current financial year is less than £500 or greater than £1000. (3) If the estimated balance falls short of £500, it is desirable that the grant should be reduced; if it exceeds £1000, the excess may be regarded as available for increasing the grant above £1000. (4) In the case of a sudden increase of the floating balance above £1000, due to an exceptionally large meeting, it is not desirable that the whole of the surplus should be spent at one meeting.

The report also contained a proposal to create three new sections, namely:—Section D, Zoology; Section I, Physiology; and Section K, Botany. The following foreign men of science have been elected by the Council as corresponding members of the Association:—Professor Christian Bohr, Copenhagen; Professor W. C. Brögger, Christiania; Professor W. Einthoven, Leyden; Professor Heger, Brussels; Dr. R. Hertwig, Munich; Dr. Hildebrand, Stockholm; and M. Henry Moissan, Paris. The Association has received an invitation to meet in Liverpool in 1896. The rest of the report of the Council dealt chiefly with subjects connected with the interior organisation of the Association.

The foregoing report was adopted, also that of the treasurer, Professor A. W. Rücker. The General Committee then voted a presentation of £100 to the assistant general secretary, Mr. George Griffith, for his arduous work in drawing up an index to the volumes of the British Association from 1861 to 1890. This most useful index is now in print. Mr. Eli Towerbutts, of Manchester, complained that before Tuesday afternoon all the tickets for seats in the body of the hall to hear Lord Salisbury's opening address had been taken, and that there was strong feeling in consequence among those who came later. One of the local secretaries said that he and his colleagues could not help it. On Monday, after the doors of the reception room were opened, a crowd of applicants for tickets burst down all barriers, and were supplied in the order of application. They unfortunately had not, at that time, a more suitable building in Oxford for the holding of the meeting of Wednesday night. The hall was two centuries old, and had never before been artificially lighted, but electric lighting had been introduced into it for the occasion.

### PRESIDENT'S ADDRESS.

The following lines are an abstract of Lord Salisbury's address, delivered on Wednesday night. Having glanced at the history of the connection of Oxford with the British Association, he went on:—

A study of the addresses of my learned predecessors in this office shows me that the main duty which it falls to a President to perform in his introductory address, is to remind you of the salient points in the annals of science since last the Association visited the town in which he is speaking. Instead, therefore, of recounting to you what has been done, or trying to forecast the discoveries of the future, I would rather draw your attention to the condition in which we stand towards three or four of the most important physical questions which it has been the effort of the last century to solve.

Of the scientific enigmas which still, at the end of the nineteenth century, defy solution, the nature and origin of what was called the elements is the most notable. It is not, perhaps, easy to give a precise logical reason for the feeling that the existence of our sixty-five elements is a strange anomaly and conceals some much simpler state of facts. But the conviction is irrestible. We cannot conceive, on any possible doctrine of cosmogony, how these sixty-five elements came into existence. A third of them form the substance of this planet. Another third are useful, but somewhat rare. The remaining third are curiosities scattered haphazard, but very scantily, over the globe, with no other apparent function but to provide occupation for the collector and the chemist. Some of them are so like each other that only a chemist can tell them apart—others differ immeasurably from each other in every conceivable particular. In cohesion, in weight, in conductivity, in melting point, in chemical proclivities they vary in every degree. They seem to have as much relation to each other as the pebbles on a sea beach, or the contents of an ancient lumber room. Whether you believe that Creation was the work of design or of inconscient law, it is equally difficult to imagine how this random collection of dissimilar materials came together. Many have been the attempts to solve this enigma; but up till now they have left it more impenetrable than before. A conviction that here was something to discover lay beneath the persistent belief in the possibility of the transmutation of other metals into gold, which brought the alchemy of the Middle Ages into being. When the immortal discovery of Dalton established that the atoms of each of these elements have a special weight of their own, and that consequently they combine in fixed ponderable proportions from which they never depart, it renewed the hope that some common origin of the elements was in sight. The theory was advanced that all these weights were multiples of the weight of hydrogen—in other words, that each elementary atom was only a greater or a smaller number of hydrogen atoms compacted by some strange machinery into one. The most elaborate analyses, conducted by chemists of the highest eminence—conspicuously by the illustrious Stas—were directed to the question whether there was any trace in fact of the theoretic idea that the atoms of each element consist of so many atoms, or even of so many half-atoms of hydrogen. But the reply of the laboratories has always been clear and certain—that there is not in the facts the faintest foundation for such a theory.

Then came the discovery of the spectral analysis, and men thought that with an instrument of such inconceivable delicacy we should at last find out something as to the nature of the atom. The result has been wholly disappointing. Spectral analysis in the hands of Dr. Huggins and Mr. Lockyer and others has taught us things of which the world little expected to be told. We have been enabled to measure the speed with which clouds of blazing hydrogen course across the surface of the sun: we have learnt the pace—the fabulous pace—at which the most familiar stars have been for ages approaching to or receding from our planet, without apparently affecting the proportions of the patterns which as far as historical record goes back they have always delineated on the evening sky. We have received some information about the elementary atoms themselves. We have learnt that each sort of atom when heated strikes upon the ether a vibration, or set of vibrations, whose rate is all its own; and that no one atom or combination of atoms in producing its own spectrum encroaches even to the extent of a single line upon the spectrum that is peculiar to its neighbour. We have learnt that the elements which exist in the stars and specially in the sun are mainly those with which we are familiar upon earth. There are a few lines in excess to which we can give no terrestrial name; and there are some still more puzzling gaps in our list. It is a great aggravation of the mystery which besets the question of the elements, that among the lines which are absent from the spectrum of the sun, those of nitrogen and oxygen stand first. Oxygen constitutes the largest portion of the solid and liquid substance of our planet, so far as we know it; and nitrogen is very far the predominant constituent of our atmosphere. If the earth is a detached bit whirled off the mass of the sun, as cosmogonists love to tell us, how comes it that in leaving the sun we cleaned him out so completely of his nitrogen and oxygen that not a trace of these gases remains behind to be discovered even by the sensitive vision of the spectroscope?

All these things the discovery of spectrum analysis has added to our knowledge; but it has left us as ignorant as ever as to the nature of the capricious differences which separate the atoms from each other, or the cause to which those differences are due.

In the last few years the same enigma has been approached from another point of view by Professor Mendeléeff. The periodic law which he has discovered reflects on him all the honour that can be earned by ingenious, laborious, and successful research. He has shown that this perplexing list of elements can be divided into families of about seven, speaking very roughly; that those families all resemble each other in this, that as to weight, volume, heat, and laws of combination the members of each family are ranked among themselves in obedience to the same rule. Each family differs from the others, but each internally is constructed upon the same plan. It was a strange discovery—strangest of all in its manifest defects. For in the plan of his families there were blanks left; places not filled up because the properly constituted elements required according to his theory had not been found to fill them. For the moment their absence seemed a weakness in the Professor's idea, and gave an arbitrary aspect to his scheme. But the weakness was turned into strength when, to the astonishment of the scientific world, three of the elements which were missing made their appearance in answer to his call. He had described beforehand the qualities they ought to have; and gallium, germanium, and scandium, when they were discovered shortly after the publication of his theory, were found to be duly clothed with the qualities he required in each. This remarkable confirmation has left Mendeléeff's periodic law in an unassailable position. But it has rather thickened than dissipated the mystery which hangs over the elements. The discovery of these co-ordinate families dimly points to some identical origin, without suggesting the method of their genesis or the nature of their common parentage. If they were organic beings all our difficulties would be solved by muttering the comfortable word "evolution"—one of those indefinite words from time to time vouchsafed to humanity, which have the gift of alleviating so many perplexities and masking so many gaps in our knowledge. But the families of elementary atoms do not breed; and we cannot therefore ascribe their ordered difference to accidental variations perpetuated by heredity under the influence of natural selection. The rarity of iodine, and the abundance of its sister chlorine, cannot be attributed to the survival of the fittest in the struggle for existence. We cannot account for the minute difference which persistently distinguishes nickel from cobalt, by ascribing it to the recent inheritance by one of them of an advantageous variation from the parent stock.

The upshot is that all these successive triumphs of research, Dalton's, Kirchhoff's, Mendeléeff's, greatly as they have added to our store of knowledge, have gone but little way to solve the problem which the elementary atoms have for centuries presented to mankind. What the atom of each element is, whether it is a movement, or a thing, or a vortex, or a point having inertia, whether there is any limit to its divisibility, and, if so, how that limit is imposed, whether the long list of elements is final, or whether any of them have any common origin, all these questions remain surrounded by a darkness as profound as ever. The dream which lured the alchemists to their tedious labours, and which may be said to have called chemistry into being, has assuredly not been realised, but it has not yet been refuted. The boundary of our knowledge in this direction remains where it was many centuries ago.

The next discussion to which I should look in order to find unsolved riddles which have hitherto defied the scrutiny of science, would be the question of what is called the ether. The ether occupies a highly anomalous position in the world of science. It may be described as a half-discovered entity. I dare not use any less pedantic word than entity to designate it, for it would be a great exaggeration of our knowledge if I were to speak of it as a body or even as a substance. When nearly a century ago Young and Fresnel discovered that the motions of an incandescent particle were conveyed to our eyes by undulation, it followed that between our eyes and the particle there must be something to undulate. In order to furnish that something, the notion of the ether was conceived, and for more than two generations the main, if not the only, function of the word ether has been to furnish a nominative case to the verb "to undulate." Lately, our conception of this entity has received a notable extension. One of the most brilliant of the services which Professor Maxwell has rendered to science has been the discovery that the figure which expressed the velocity of light, also expressed the multiplier required to change the measure of static or passive electricity into that of dynamic or active electricity. The interpretation reasonably affixed to this discovery is that, as light and the electric impulse move approximately at the same rate through space, it is probable that the undulations which convey them are undulations of the same medium. And as induced electricity penetrates through everything, or nearly everything, it follows that the ether through which its undulations are propagated must pervade all space, whether empty or full, whether occupied by opaque matter or transparent matter, or by no matter at all. The attractive experiments by which the late Professor Herz illustrated the electric vibrations of the ether will only be alluded to by me, in order that I may express the regret deeply and generally felt that death should have terminated prematurely the scientific career which had begun with such brilliant promise and such fruitful achievements. But the mystery of the ether, though it has been made more fascinating by these discoveries, remains even more inscrutable than before. Of this all-pervading entity we know absolutely nothing except this one fact, that it can be made to undulate. Whether, outside the influence of matter on the motion of its waves, ether has any effect on matter or matter upon it, is absolutely unknown. And even its solitary function of undulating ether performs in an abnormal fashion which has caused infinite perplexity. All fluids that we know transmit any blow they have received by waves which undulate backwards and forwards in the path of their own advance. The ether undulates athwart the path of the wave's advance. The genius of Lord Kelvin has recently discovered what he terms a labile state of equilibrium, in which a fluid that is infinite in its extent may exist, and may undulate in this eccentric fashion without outraging the laws of mathematics. I am no mathematician, and I cannot judge whether this reconciliation of the action of the ether with mechanical law is to be looked upon as a permanent solution of the question, or is only what diplomatists call a *modus vivendi*. In any case it leaves our knowledge of the ether in a very rudimentary condition. It has no known qualities except one, and that quality is in the highest degree anomalous and inscrutable. The extended conception which enables us to recognise ethereal waves in the vibrations of electricity has added infinite attraction to the study of those waves, but it carries its own difficulties with it. It is not easy to fit in the theory of electrical ether waves with the phenomena of positive and negative electricity, and as to the true significance and cause of those counteracting and complementary forces, to which we give the provisional names of negative and positive, we know about as much now as Franklin knew a century and a-half ago.

I have selected the elementary atoms and the ether as two instances of the obscurity that still hangs over problems which the highest scientific intellects have been investigating for several generations. A more striking but more obvious instance still is Life—animal and vegetable Life—the action of an unknown force on ordinary matter. What is the mysterious impulse which is able to strike across the ordinary laws of matter, and twist them for a moment from their path? Some people demur to the use of the term "vital force" to designate this impulse. In their view the existence of such a force is negatived by the fact that chemists have been able by cunning substitutions to produce artificially the peculiar compounds which in nature are only found in organisms that are or have been living. These compounds are produced by some living organism in the performance of the ordered series of functions proper to its brief career. To counterfeit them—as has been done in numerous cases—does not enable us to do what the vital force alone can effect—to bring the organism itself into existence, and to cause it to run its appointed course of change. This is the unknown force which continues to defy not only our imitation but our scrutiny. Biology has been exceptionally active and successful during the last half century. Its triumphs have been brilliant, and they have been rich enough not only in immediate result, but in the promise of future advance. Yet they give at present no hope of penetrating the great central mystery.

Lord Salisbury then proceeded to consider the relations of the geologist and the mathematician with the biologists, showing that their claims were contradictory, the latter assuming an antiquity for the earth which the others refused to admit, and then went on:—

Of course, if the mathematicians are right, the biologists cannot have what they demand. If, for the purpose of their theory, organic life must have existed on the globe more than a hundred million years ago, it must, under the temperature then prevailing, have existed in a state of vapour. The jelly-fish would have been dissipated in steam long before he had had a chance of displaying the advantageous variation which was to make him the ancestor of the human race. The gravest objection to the doctrine of natural selection was expressed by Weismann in a paper published a few months ago, not as agreeing to the objection, but as resisting it; and, therefore, his language may be taken as an impartial statement of the difficulty. 'We accept natural selection,' he says, 'not because we are able to demonstrate the process in detail, not even because we can with more or less ease imagine it, but simply because we must—because it is the only possible explanation that we can conceive. We must assume natural selection to be the principle of the explanation of the metamorphoses, because all other apparent principles of explanation fail us, and it is inconceivable that there could yet be another capable of explaining the adaptation of organisms without assuming the help of a principle of design."

There is the difficulty. We cannot demonstrate the process of natural selection in detail; we cannot even, with more or less ease, imagine it. It is purely hypothetical. No man, so far as we know, has ever seen it at work. An accidental variation may have been perpetuated by inheritance, and in the struggle for existence the bearer of it may have replaced, by virtue of the survival of the fittest, his less improved competitors; but as far as we know no man or succession of men have ever observed the whole process in any single case, and certainly no man has recorded the observation. Variation by artificial selection, of course, we know very well; but the intervention of the cattle breeder and the pigeon fancier is the essence of artificial selection. It is effected by their action in crossing, by their skill in bringing the right mates together to produce the progeniture they want. But in natural selection who is to supply the breeder's place? Unless the crossing is properly arranged, the new breed will never come into being. What is to secure that two individuals of opposite sexes in the primeval forest, who have been both accidentally blessed with the same advantageous variation, shall meet, and transmit by inheritance that variation to their successors? Unless this step is made good, the modification will never get a start; and yet there is nothing to ensure that step, except pure chance. The law of chances takes the place of the cattle breeder and the pigeon fancier. The biologists do well to ask for an immeasurable expanse of time, if the occasional meetings of advantageously varied couples from age to age are to provide the pedigree of modifications which unite us to our ancestor the jelly-fish. Of course the struggle for existence, and the survival of the fittest, would in the long run secure the predominance of the stronger breed over the weaker. But it would be of no use in setting the improved breed going. There would not be time. No possible variation which is known to our experience, in the short time that elapses in a single life between the moment of maturity and the age of reproduction, could enable the varied individual to clear the field of all competitors, either by slaughtering or starving them out. But unless the struggle for existence took this summary and internecine character, there would be nothing but mere chance to secure that the advantageously varied bridegroom at one end of the wood should meet the bride, who by a happy contingency had been advantageously varied in the same direction at the same time at the other end of the wood. It would be a mere chance if they knew of each other's existence—a still more unlikely chance that they should resist on both sides all temptations to a less advantageous alliance. But unless they did so, the new breed would never even begin, let alone the question of its perpetuation after it had begun. I think Professor Weismann is justified in saying that we cannot, either with more or less ease, imagine the process of natural selection.

It seems strange that a philosopher of Professor Weismann's penetration should accept as established a hypothetical process the truth of which he admits that he cannot demonstrate in detail, and the operation of which he cannot even imagine. The reason that he gives seems to me instructive of the great danger scientific research is running at the present time—the acceptance of mere conjecture in the name and place of, knowledge, in preference to making frankly the admission that no certain knowledge can be attained. "We accept natural selection," he says, "because we must—because it is the only possible explanation that we can conceive." As a politician, I know that argument very well. In political controversy it is sometimes said of a disputed proposal that it "holds the field," that it must be accepted because no possible alternative has been suggested. In politics there is occasionally a certain validity in the argument, for it sometimes happens that some definite course must be taken, even though no course is free from objection. But such a line of reasoning is utterly out of place in science. We are under no obligation to find a theory, if the facts will not provide a sound one. To the riddles which nature propounds to us the profession of ignorance must constantly be our only reasonable answer. The cloud of impenetrable mystery hangs over the development and still more over the origin of life. If we strain our eyes to pierce it, with the foregone conclusion that some solution is and must be attainable, we shall only mistake for discoveries the figments of our own imagination. Professor Weismann adds another reason for his belief in natural selection which is certainly characteristic of the time in which we live. "It is inconceivable," he says, "that there should be another principle capable of explaining the adaptation of organisms without assuming the help of a principle of design." The whirligig of time assuredly brings its revenges. Time was, not very long ago, when the belief in creative design was supreme. Even those who were sapping its authority were wont to pay it a formal homage, fearing to shock the public conscience by denying it. Now the revolution is so complete that a great philosopher uses it as a *reductio ad absurdum*, and prefers to believe that which can neither be demonstrated in detail, nor imagined, rather than run the slightest risk of such a heresy.

I quite accept the Professor's dictum that, if natural selection is rejected, we have no resource but to fall back on the mediate or immediate agency of a principle of design. In Oxford, at least, he will not find that argument is conclusive; nor, I believe, among scientific men in this country generally, however imposing the names of some whom he may claim for that belief. I would rather lean to the conviction that the multiplying difficulties of the mechanical theory are weakening the influence it once had acquired. I prefer to shelter myself in this matter behind the judgment of the greatest living master of natural science among us, Lord Kelvin, and to quote as my own concluding words, the striking language with which he closed his address from this chair, more than twenty years ago: "I have always felt," he said, "that the hypothesis of natural selection does not contain the true theory of evolution, if evolution there has been in biology. . . . I feel profoundly convinced that the argument of design has been greatly too much lost sight of in recent zoological speculations. Overpoweringly strong proofs of intelligent and benevolent design lie around us, and if ever perplexities, whether metaphysical or scientific, turn us away from them for a time, they come back upon us with irresistible force; showing to us through nature the influence of a free will, and teaching us that all living things depend on one everlasting Creator and Ruler."

The section which represents mechanical science, and chiefly applied mechanics from the engineer's point of view, meets in Keble College Hall, a hall which is usually devoted to much more festive occupation. Tables are turned aside to make room for seats and diagrams, and gastronomics will give place to discussions on subjects which provide the means for its study. An unusually large number of papers has been sent in before the commencement of the meeting, and a programme occupying the whole of the available time of the first five days of the meeting has been arranged. The following is the programme which will probably be followed:—

*Thursday, August 9th.*

Address by President, Professor A. B. W. Kennedy, LL.D., F.R.S.

Sir F. J. Bramwell, F.R.S., "Some Reminiscences of Steam Locomotion on Common Roads."

H. Davey, M. Inst. C.E., "Borehole Wells for Town Water Supply."

*Friday, August 10th.*

Joint meeting with Section A:—(*a*) Professor O. Henrici, F.R.S., "On Integrators, Harmonic Analysers and Integraphs, and their Application to Physical and Engineering Problems." (*b*) Discussion on flight. Joint discussion with Section A.

Lord Kelvin, President Royal Society, "On the Resistance Experienced by Solids moving through Fluids."

Professor T. Claxton Fuller, M. Inst. C.E., "The Strength and Plastic Extensibility of Iron and Steel."

M. Fitzmaurice, M. Inst. C.E., "Tunnel Construction by means of Shield and Compressed Air, with Special Reference to the Tunnel under the Thames at Blackwall."

*Saturday, August 11th.*

Sir A. Noble, C.B., F.R.S., "On the Measurement of the Pressures developed in the Bores of Guns."

B. Donkin, M. Inst. C.E., "The most Economical Temperature for Steam Engine Cylinders."

J. Kenward, F.S.A., "Lighthouse Apparatus, and Lighthouse Administration in 1894."

*Monday, August 13th.*

T. Parker, F.R.S.E., M. Inst. C.E., M. Inst. M.E., "Continuous Current Distribution of Electricity at High Voltage, being a description of the Lighting of the City of Oxford."

W. H. Preece, F.R.S., "Signalling through Space."

Professor S. P. Thompson, F.R.S., "Some Advantages of Alternate Currents."

H. Lea, M. Inst. C.E., "A Special Chronograph."

G. M. Clark, "A Direct-reading Platinum Pyrometer."

*Tuesday, August 14th.*

Professor W. C. Unwin, F.R.S., "Report of Committee on Dryness of Steam."

H. F. Burstall, M.A., A.M.I.C.E., "The Temperature Entropy Diagram."

J. Swinburne, "The Hunting of Governed Engines."

Professor D. S. Capper. M.A., M. Inst. C.E., "Engineering Laboratory Instruments and their Calibration."

Professor T. Hudson Beare, B.Sc., M. Inst. C.E., "Experiments on the effect of Piston Speed on Steam Economy."

Professor Everitt, "Spring Spokes for Bicycles."

Mr. E. G. Coker on "Torsional Strength of Solid and Hollow Shafts."

From this it will be seen that the programme is varied, and promises to afford the section plenty of interesting occupation.

The paper by Sir Frederick Bramwell is just now of peculiar interest, as showing how far mechanical engineers of from one to two generations ago were in advance of those of the present day in the conveyance of passengers by steam on common roads. They had arrived experimentally at results which it is not too much to say could not be surpassed even to-day with all the advantages of constructive facility which we now possess. These facilities we have not been able to employ to our advantage in consequence of legal restrictions which exist in no other country. The result is that while we were leading in steam conveyance on common roads from thirty to forty years ago, we are now very far behind those of some other countries, as has been abundantly proved in the recent competitive trials of road carriages in France, as reported in our columns. These trials have recalled attention to this subject, and few have in recent times so greatly interested mechanical engineers. The necessity for some change in our laws as affecting steam on common roads has for a long time been impressed on those who use agricultural locomotives, and the possibility now proved of using light vehicles for daily use is bringing the subject more prominently forward. We shall publish Sir Frederick Bramwell's paper in another impression.

## SIXTH INTERNATIONAL CONGRESS ON INLAND NAVIGATION.

(*By our Special Commissioner.*)

The numbers of members attending the Congress increased from day to day. At the first meeting on the Monday about 300 had notified their arrival, and during the week this number was nearly doubled. The subjects which provoked most discussion were the question of tolls and the training of rivers.

On the 27th ult. a large party left by special train for Amsterdam, where steamers were in readiness to take the visitors to the entrance works of the new canal for connecting the port with the Rhine *viâ* the Mermede. The sewage of Amsterdam is syphoned under this canal into the Zuyder Zee. The entrance locks built two years ago to accommodate the large Rhine barges were passed. The steamers then turned back.

The Canal du Rhin enters the port at its easterly limit, and the steamers proceeded along the front of the quays and wharves for a distance of nearly six miles, to the newly constructed petroleum harbour, three-quarters of a mile west of Hoathaven. Several miles of quays were passed provided with warehouses, sheds, and lines of railway, all ready to deal with a large traffic, and statistics show that the tonnage by the Amsterdam Ship Canal has grown from 3,965,192 tons in 1877, the year in which the Canal was opened, to 10,485,138 tons in 1892. During the same period, the register tonnage of all vessels using the port has increased from 2,431,715 tons to 4,512,347 tons. The number of vessels remains almost exactly the same, although the tonnage has increased 86 per cent. Plans have been prepared for extending the quays and accommodation generally whenever the conditions of the trade of the port render this desirable.

Having returned to the landing stage near the centre of the port the company disembarked and partook of the hospitality of the city of Amsterdam, an excellent luncheon being provided in two large rooms at the railway station. After doing justice to this, a move was made to Ymuiden by special train, where the new lock under construction was visited. The foundations are laid on fine sand, no piles are employed, but the walls and chamber, as well as the gate platforms, rest on concrete. The walls are almost entirely of brick. The gate sills, hollow quoins, square quoins, and coping, are of limestone; lime, mortar mixed with sand, is employed in building the walls. The dimensions of the lock are 740ft. long, 82ft. wide, depth below the level of canal 31ft. 6in. The Government have specified these dimensions to enable the largest ships of war to enter and use the canal when necessary. The largest lock of the existing entrance is small in comparison, being no more than 393ft. 6in. long, 59ft. wide, and 24ft. 6in. below canal level. The new lock is to be connected with the existing ship canal and harbour by a cutting $1\frac{2}{3}$ miles in length, having a bottom width of 105ft. 6in., a depth of 26ft. 10in. below canal level, and slopes below water of about 5 to 1. It will be observed that the depth of the lock sills will allow of considerable deepening of this canal. The estimated cost of the works is £550,000, and they are expected to be completed in 1896.

Steamers were again provided to take the members to look at the piers and the outer harbour of Ymuiden. This was a very enjoyable part of the day's proceedings. Three dredgers were at work, and these are required to remove about 800,000 cubic yards of sand and silt per annum to keep open the channel from the dock to the North Sea.

The final meeting of the Congress was held in the Great Hall of the Academy on Saturday, July 28th. During the earlier proceedings this had been occupied by No. I. section, in which papers were read on canal construction. Section II. dealt more particularly with the difficulties encountered in breaking up ice and clearing navigations of this obstruction, as described in our last impression. Drawings of steamers especially built for the purpose were exhibited.

Section III. was devoted to the consideration of the toll question, and Section IV. with the training of rivers. All the sections held their meetings in the same building, which was a great convenience. Unfortunately, many of the papers had not been translated into English or French, and the discussions were not as full as they would otherwise have been.

A very important question was submitted to the final meeting, viz., whether the International Congresses on inland navigation and on maritime works, viz., docks and harbours, should continue to be held separately or be united. After considerable discussion, in which the representatives of England, France, and most other countries—Germany alone dissenting—spoke in favour of amalgamation, it was voted that the two should henceforward be fused under the title of the "Congress on Navigation." It was further determined that the invitation of the representatives of Italy to hold the next Congress in that country should be accepted.

After a hearty expression of thanks to our Dutch hosts for the very kind manner in which they had received the members, and for the great and successful exertions made for their entertainment, both mental and physical, the Congress separated.

In the evening the Comte and Comtesse de Bylandt held a reception, to which members of the Congress were invited, and they will long remember the noble and generous manner in which they were entertained.

On the 30th the excursion was to Haarlem, and the great pumps for draining Haarlemeer were visited. Eight pumps 6ft. in diameter, with a stroke 9ft. 10in., are placed at Linden, and lift the water a height of 16ft. 5in. Seven of these were at work and one in reserve. This machine, with another of eleven pumps 5ft. 3in. diameter, with a similar stroke and lift, are employed to pump an area of 18,100 hectares, or 44,700 acres.

At Haarlem the party embarked on a steamer which proceeded to the Amsterdam Ship Canal and along the canal for several miles to Zaandam, noted for its numerous windmills, and as having been the residence of Peter the Great when he betook himself to learning the art of shipbuilding.

It was noticed what an effective protection was afforded to the slopes of the canal by the reeds growing along its edge. These are self-sown on the Herm. A railway bridge was opened for the passage of the steamer, and as this line has been made since the Ship Canal was constructed, it shows that the Dutch are not afraid of swing bridges. At first the Vetser Bridge was the only crossing.

## LEGAL INTELLIGENCE.

### NISI PRIUS COURT, MANCHESTER.

(*Before* Mr. Justice Collins *and a Special Jury.*)

REDDAWAY *v.* BANHAM.

The hearing of this case, which was commenced on Wednesday, July 18th, was resumed on the 21st. Mr. Gully, Q.C., M.P., Mr. Byrne, and Mr. J. C. Graham, were for the plaintiffs, Mr. F. Reddaway and Messrs. F. Reddaway and Co., belt manufacturers; while Mr. Bigham, Q.C., Mr. M'Call, Q.C., and Mr. Sutton, were for the defendants, Mr. George Banham and Messrs. G. Banham and Co., also belt manufacturers. The action was brought to obtain an injunction restraining the defendants from continuing to use the word "camel" in such a manner as to deceive purchasers into the belief that they were getting goods manufactured by the plaintiffs, and also to recover damages. It was stated that Mr. Reddaway had used the term "camel hair belting" since 1879, and has spent about £18,000 in advertising it. He had adopted the figure of a camel as a trade mark. It was now, he stated, well known throughout the world, particularly in India, and it was part of the plaintiffs' case that camel hair belting had become synonymous with Reddaway's belting. In 1891 Mr. Reddaway found that a number of other firms had taken the name. In one case he took legal proceedings and obtained an injunction, and in all the other cases, except one, his competitors ceased to use the name camel hair belting, the exception being the present defendants.

When the hearing of the case was resumed on the 21st the Judge, in reply to Mr. Bigham, said the question at issue must go to the jury.

Mr. Bigham urged that there was no case to go before the jury, inasmuch as no injunction could restrain a man from correctly describing his goods as being made of a certain material.

The Judge said he would take a note of the objection.

Mr. Bigham, in opening the case for the defendants, pointed out that the action was not brought to restrain them from infringing a patent. Mr. Reddaway did not object to Mr. Banham making a belting exactly similar to his own in every respect, but what he did object to was that Mr. Banham should call it camel-hair belting. Counsel denied Mr. Reddaway's right to raise this objection, and contended that any man might describe his goods as being of a certain material, or as being made in a certain way, and so long as the description was true nobody could interfere with him. As a matter of law he was entitled to say of his goods what was the truth. He proposed to show the jury by abundant proof that the material used by Mr. Banham, like that used by Mr. Reddaway, was camel-hair yarn; and if he could satisfy them on that point he should ask the Judge to tell them that the defendants were entitled so to describe their goods, and so to stamp, invoice, and sell them. It appeared to him therefore that the whole question upon which the case turned was, aye or no, was this camel-hair belting truly described?

Evidence was given by expert witnesses to show that the defendants' belting was made of camels' hair.

Mr. George Banham, in cross-examination by Mr. Gully, said there might or might not be a written agreement between George Banham and Co. and Julius Rolla, of Frankfort, granting the sole agency for the sale of Banham's manufactures in Germany to the latter person. Subsequently he admitted that there was such an agreement, but explained that he did not know whether the agreement was "ratified" or not. He had got counsel's opinion to the effect that the agreement was not valid. A circular issued by Rolla advertising Banham's camel-hair belting was a little different from a similar circular of Reddaway's, but not much. He never saw the circular till July, 1893, when he wrote to tell Rolla to discontinue using it. He was not aware that Rolla was still using the circular.

The Judge, in summing up, told the jury that the one question that lay at the root of the whole matter was whether the name "camel-hair belting" was so closely identified with the plaintiffs' manufacture that in the market and among people who dealt in the material the term was understood to mean Reddaway's belting. The plaintiffs' case depended upon their being able to prove that condition, and should they fail to establish it they had no case at all. His Lordship pointed out that even although the defendants' description of their belting was a true description, yet that would not be a conclusive argument in their favour if the jury were of opinion that the term "camel-hair belting" had acquired on the market, *prima facie*, the meaning "Reddaway's belting." In conclusion the Judge handed the jury a list of four questions which he desired them to answer, yes or no.

The jury returned twice, each time professing their inability to answer the questions, but at the same time stating that they had arrived at a "plain verdict." His Lordship urged them on each occasion to reconsider the matter. In mercy to the parties, he remarked, they ought to come to a conclusiom on each and all of the questions. Eventually the jury agreed, replying to the different questions as follows:—

(1) Does camel-hair belting mean belting made by the plaintiffs as distinguished from belting made by other manufacturers?—Yes.

(2) Or does it mean belting of a particular kind without reference to any particular maker?—No.

(3) Do the defendants so describe their belting as to be likely to mislead purchasers and to lead them to buy the defendants' belting as and for the belting of the plaintiffs?—Yes.

(4) Did the defendants endeavour to pass off their goods as and for the goods of the plaintiffs so as to be likely to deceive purchasers?—Yes.

In accordance with this verdict his Lordship gave judgment for the plaintiffs with costs on the higher scale.—*Manchester Guardian.*

Naval Engineer Appointments.—The following appointments have been made at the Admiralty:—Fleet engineers: Frederick G. Whittaker, to the Conquest; C. E. Stewart to the Vivid, additional, as engineer overseer of her Majesty's ships Dido and Isis. Staff engineers: John W. Hole, to the Talbot; William S. Stribling, to the Hecate; Charles Dawe, to the Majestic. Chief engineer: John M. Downer, to the Seahorse, to date July 1st. Engineers: R. D. Donohue, to the Traveller, to date July 18th; John W. Pleming and J. H. Barry to the Dryad, to date July 20th. Acting engineer: William H. Beckett to the Royal Arthur.

## TO CORRESPONDENTS.

**Registered Telegraphic Address, "ENGINEER NEWSPAPER, LONDON."**

*** *In order to avoid trouble and confusion, we find it necessary to inform correspondents that letters of inquiry addressed to the public, and intended for insertion in this column, must in all cases be accompanied by a large envelope legibly directed by the writer to himself, and bearing a penny postage stamp, in order that answers received by us may be forwarded to their destination. No notice can be taken of communications which do not comply with these instructions.*

*** *We cannot undertake to return drawings or manuscripts; we must therefore request correspondents to keep copies.*

*** *All letters intended for insertion in* THE ENGINEER, *or containing questions, should be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever can be taken of anonymous communications.*

C. W. V.—*(1) We believe that the pumping engine business has been closed, but the mining machinery business is carried on as heretofore. (2) From four to five years ago. We cannot answer the second part of this question.*

B. A. T.—*Many rotary meters have been patented. Yours is but a modification. None of them are positive. They all pass more water than the theoretical quantity, because of leakage past the vanes. Consequently they have each to be calibrated and its coefficient ascertained. But this coefficient only holds good for a stated pressure and rate of revolution. As a rule the percentage of leakage increases very rapidly as the quantity of water passed diminishes. Your scheme does not get over this objection.*

J. D. (Brighton).—*The American yacht Vigilant is not in the least like the old style of cutter yachts. She has sloping spoon-shaped bows. She has the equivalent of a great fixed centre board, at the bottom of which is a large mass of lead ballast shaped as a parabolic spindle of least resistance. There is next to no dead wood at the bow or stern, and no keel in the usual sense of the term. She is more like a gigantic "half rater" perhaps, than anything else, and the absence of dead wood enables her, like a half rater, to turn almost in her own length. She is painted light French grey, nearly white. The Britannia is painted black.*

### SUBSCRIPTIONS.

THE ENGINEER *can be had, by order, from any newsagent in town or country at the various railway stations; or it can, if preferred, be supplied direct from the office on the following terms (paid in advance):—*

*Half-yearly (including double number)* .. .. £0 14s. 6d.
*Yearly (including two double numbers)*.. .. £1 9s. 0d.

*If credit occur, an extra charge of two shillings and sixpence per annum will be made.* THE ENGINEER *is registered for transmission abroad.*

*A complete set of* THE ENGINEER *can be had on application.*

*In consequence of the reduction of postage on newspapers to one uniform rate for any destination outside the United Kingdom, Foreign Subscriptions will, until further notice, be received at the rates given below. Foreign Subscribers paying in advance at these rates will receive* THE ENGINEER *weekly and post free. Subscriptions sent by Post-office Order must be accompanied by letter of advice to the Publisher.*

THIN PAPER COPIES—
*Half-yearly* .. .. .. £0 18s. 0d.
*Yearly* .. .. .. £1 16s. 0d.
THICK PAPER COPIES—
*Half-yearly* .. .. .. £1 0s. 3d.
*Yearly* .. .. .. £2 0s. 6d.

READING CASES.—*The Publisher has in stock reading cases which will hold thirteen copies of* THE ENGINEER. *Price 2s. 6d. each.*

### ADVERTISEMENTS.

*** *The charge for advertisements of four lines and under is three shillings, for every two lines afterwards one shilling and sixpence; odd lines are charged one shilling. The line averages seven words. When an advertisement measures an inch or more, the charge is ten shillings per inch. All single advertisements from the country must be accompanied by a Post-office Order in payment. Alternate Advertisements will be inserted with all practical regularity, but regularity cannot be guaranteed in any such case. All except weekly advertisements are taken subject to this condition.*

*Prices for Displayed Advertisements in "ordinary" and "special" positions will be sent on application.*

**Advertisements cannot be inserted unless delivered before Six o'clock on Thursday evening; and in consequence of the necessity for going to press early with a portion of the edition, ALTERATIONS to standing advertisements should arrive not later than Three o'clock on Wednesday afternoon in each week.**

*Letters relating to Advertisements and the Publishing Department of the paper are to be addressed to the Publisher, Mr. Sydney White; all other letters to be addressed to the Editor of* THE ENGINEER.

### MEETINGS NEXT WEEK.

THE JUNIOR ENGINEERING SOCIETY.—August 18th to 25th. Summer excursion to Cardiff and District. Saturday morning, August 18th, leave Paddington—G.W. Railway—for Weston-super-Mare. Monday, Cardiff, Bute Docks, Cardiff Iron and Steel Works of the Dowlais Iron Company, and the Cardiff and Tin Stamping and Enamel Works. Tuesday, new coal pits of the Dowlais Iron Company, and Cyfarthfa Ironworks in the morning; Tin-plate Works and Llandaff Cathedral in the afternoon. Wednesday, Barry Docks, Cardiff Electric Light Station. Thursday, Newport, Mon., steamer from Cardiff for trip up the Bristol Channel and River Usk, St. Julian's Brickworks, Newport Ropery Works, Alexandra Docks, Isca Foundry, Spittle's Foundry, and Mordey, Carney, and Company's Dry Docks. Friday, visit Taff Vale Railway Locomotive Shops, Lloyd's Bute Proving House, Works of the South Wales Glass Manufacturing Company, and a Railway Carriage and Wagon Works. Saturday morning, August 25th, Tintern, Wye Valley, Tintern Abbey, Portskewett Pumping Station of the Severn Tunnel, London *viâ* Severn Tunnel.

# THE ENGINEER.

*AUGUST* 10, 1894.

### THE MARINE BOILER OF THE FUTURE.

THE papers read before the Institution of Naval Architects at the last three meetings of this body held respectively in Cardiff, London, and Southampton, and the discussions which followed, supply ample evidence that an important change in marine boiler construction is imminent. It has, of course, been long known in a general way that various forms of boilers, more or less unlike the Scotch boiler, were finding favour with the Admiralty and with shipowners. But the proceedings of the Institution of Naval Architects have given form and substance to various more or less vague statements. Indeed, it is one of the special functions of such associations to collect facts and to aggregate them; and to substitute definite and precise information for vague rumours. In spite of very free denials, it is now indisputable that shipowners are beginning to look with favour on the water-tube generator. Matters are now indeed in very much the same condition as they were twenty-five years ago.

The compound engine was then being tried with caution and hesitation. Setting aside such vessels as the Thetis and Propontis, which worked at fairly high pressures, numerous ships could be named in which pressures of 30 lb. and 35 lb. were used with compound engines and surface condensers. The success attained was such that engineers took heart of grace and ventured to make boilers carrying 60 lb. No harm followed. These boilers did not blow up or burn out, and they gave the compound engine a chance. Then came thick steel plates and corrugated flues; and so pressures crept up, and the triple-expansion engine was among us almost unawares. Improvement after improvement was made in the engine, but the type of boiler remained the same. From first to last the advance was made with difficulty. There were unceasing disputes with the Board of Trade, which very vigorously opposed the effort to carry high pressures in the Scotch, or indeed in any other kind of boiler. When pressures of 160 lb. had been reached a lull ensued, and for about ten years very little has been done in the way of change. Various causes have, nevertheless, been silently at work; among these may be mentioned the extreme lowness of freights, which has rendered economy of fuel imperative. The demand for high speeds; the adoption of forced or assisted draught; the failure of Admiralty boilers; all these things have operated to stimulate invention—and what is more to the purpose, to induce engineers and shipowners to consider inventions however audacious, instead of putting them aside almost without a thought.

Thus, then, we find ourselves now in the midst of a change in marine boiler engineering; and it is well that engineers and shipowners should consider in what direction they are drifting. The man who maintains that things as they are are good enough for him, will find himself out of the race in a very brief period. It is a quite familiar fact that none of the older class of steamers can be made to pay. We doubt if there is now running any screw steamer, of fair size, with compound engines. Mr. Asplin's engines in Messrs. Leyland's steamers are, it is true, compound; but they are really, if we may say so, triple-expansion engines with the intermediate cylinder suppressed, working with high ratios of expansion and high pressures. Just as the compound engine and 80 lb. steam cannot compete with the triple-expansion engine and 160 lb. steam, so it will be found that these last cannot compete with engines working with 200 lb. steam, generated in boilers differing more or less from the Scotch boiler. This pressure is not in extended use yet, but it will be in a very short time—possibly by the end of the year. The question is, what will the new steam generator be? At the present moment every marine engine building firm of importance throughout the kingdom is either patenting, experimenting with, or building water-tube boilers of some kind. It remains, of course, to be seen which of all these will survive the test of a life at sea. Possibly the water-tube boiler of the future has yet to be invented or discovered. On the other hand, those who perused Mr. Ellis' paper read last year at Cardiff, and Mr. Gross' paper read this year at Southampton, cannot fail to see that Sir J. Brown and Co. are determined that the Scotch type of boiler shall not be superseded without a struggle. The results obtained with the Serve tube and induced draught have been so far, remarkable and satisfactory in the highest degree, and we specially commend Mr. Gross' paper, as published in our last impression, to the attention of our shipowning readers. Mr. Gross' reply to the criticisms passed on this paper was extremely impressive—much more impressive than can be gathered from any report of the discussion. It must be understood that what he had read was read in the presence of men highly competent to dispute the accuracy of his statements or the soundness of his reasoning. The impressiveness of his reply was due to the way in which he explained the scrupulous care that had been taken to eliminate every doubtful statement. He himself, or the other representatives of Sir John Brown and Co., might be quite certain of a given truth, but unless the evidence was not only sufficient to give them certainty, but to be absolutely irrefragable in the widest sense as well, Mr. Gross said nothing about it in his paper. It is to be remembered that the efficiency of the Serve tube is a thing on the whole opposed to the results of the researches of such men as Peclet. Then, again, that air heating tubes should take up heat as they do is contrary to the experience of inventors of hot air engines; but there are the facts, and if they do not agree with theory, so much the worse for the theory.

But it is not the Serve tube alone that commands success. Mr. Gross consumes heroic quantities of coal in comparatively small furnaces, and neither burns his grate nor his boiler. Mr. Martin has for years advocated induced draught, and got well laughed at for his pains. But there is an old adage which says that "he laughs best who laughs last," and we fancy that Mr. Martin will laugh last in this case. No doubt it does seem absurd that if air is drawn through a fire by a fan at the root of the chimney the boiler will not be injured; whereas if the same fan forced air through the fire, leakage would be set up at the tube ends. But it only seems absurd because we are so ignorant of what really takes place in a boiler and a furnace. There is, again, no tangible reason why raising the inner ends of the grate bars 3in. or 4in. should prevent them from being melted. Neither Mr. Ellis nor Mr. Gross has suggested any explanation of the fact, but there it is. Bars, which, when set in the ordinary way, are melted in half-an-hour, will endure a month's incessant steaming with little injury when set as Mr. Gross has described. With his facts and his figures before him, we are not surprised to find that Mr. Gross thinks that as much may be done with the Scotch boiler as with any water-tube boiler in the market. Then we have Mr. Howden. He prejudices his own case by injudicious statements; but solid facts remain, and prove that he has certainly effected improvements of great value. No doubt all these changes in construction represent augmented first cost; but the shipowner cares next to nothing for this if only he can see his way to an adequate return for his money. The inventor need not be deterred by the cost of his invention; but he must be prepared to prove that the outlay will pay.

It may be asked what is the benefit to be derived from the use of tubulous boilers, or Howden's system, or the Serve tube, or any other device of the kind, seeing that none of them claim to effect any enormous augmentation of economical efficiency. The reply is that at sea a saving in weight and space is often of quite as much value as a considerable saving in coal. Thus, for example, if a boiler-room can be shortened 2ft. or 3ft., that usually means an addition to the cargo space of the entire cross-section of the ship 2ft. or 3ft. long. A saving in coal again means not only the saving in the cost of fuel, but a reduction in bunker space. Again, increased boiler efficiency, weight for weight, means, other things being equal, an increase in power and speed, which may be matters of very great, or in warships of the last, importance. But beyond all these things there is a curious and most influential element in the whole matter, the effect of which must not be overlooked. This is fashion. It is certain that mankind is imitative in every phase of life. If one shipowner adopts an improvement, somebody else is certain to follow suit. Thus we sincerely believe that if water-tube boilers became the fashion it would be next to impossible to get an order for any other type of generator. It is not to be supposed that this follow-my-neighbour system is adopted blindly or without due reason, at all events at first; on the contrary, it is usually the result of a sincere conviction that what is done by majority is right. But be this as it may, we have the fact that at the present moment the unmodified Scotch boiler is going out of fashion, and something else is coming in. What that will be remains to be seen. If Sir John Brown and Co. can get such results in the future, and on an extended scale, as are set forth in Mr. Gross' paper, it would be rash to assert that the tubulous boiler is going to have it all its own way.

### AMERICAN ARMOUR.

WE fear that our readers must have had too much of armour lately. It is therefore desirable to deal with certain recent matters very briefly, although there are some points of interest and considerable importance. We have received further accounts of the Government investigation of the Carnegie plates on which fines were exacted. There is, however, in all these nothing that we can see to shake the view that we endeavoured to put before our readers. The armour-plates we think were very likely quite up to the standard of those that are accepted generally and used on the sides of the finest ships afloat. We think that the United States Government used the condition laid down as to manufacture in a way that pressed very hardly, if not unfairly, on makers. At the same time, all this refers to degrees of excellence to be attained; now the main point at issue was the tampering with plates after selection. Mr. Frick says he knew nothing of it; but he surely does not need to be told that the head of a great establishment is responsible for what takes place, and if he employs men who throw dust in his eyes the consequences must in all fairness fall on him, not on the Government, especially as by some means they discovered for themselves what he ought to have discovered. The matter does not really call for further remark.

To pass on to other questions. Two contradictory reports appear in the *Times* of August 2nd and August 7th of an important trial of a Harvey 17in. or 18in. plate made at Carnegie's according to the former account, and at Bethlehem according to the latter. It was attacked by 12in. projectiles weighing 850 lb. The first shot struck with a velocity of either 1410 or 1465 foot-seconds. The second with 1858, or else with 1926 foot-seconds, according to which account is correct. We give the figures of the report of August 2nd in each case first. The discrepancy in the accounts of the results obtained are much greater than in the above figures. According to the account of August 2nd, the first shot, a Carpenter projectile, "burrowed" 13·6in. into the plate, and rebounded practically intact. The second, a Wheeler Stirling shot—the first of this kind yet tried—went through the plate, through 42in. of oak backing and 3ft. of support, then through 15ft. of earth, and "out over the hill and through the woods 300ft. beyond." Its original point had been fused and bruised away, as had that of the first shot, while several spiral cracks on the surface reached half way down the body. The shot hole made by the first round had a "halo" of fine cracks, 4in. wide. That of the second had a bulge 26in. in diameter, and 1·4in. high, with "only twenty-seven radial cracks about 5in. or 6in. long." The plate appeared rather harder and flaked more at the second point of impact. In the *Times* of August 7th, Mr. Fox, writing as the agent to the Harvey Steel Company, tells us that the plate had structural defects and was unfit for test. It was 18in. thick, not 17in. It was from Bethlehem, not from Carnegie's. The first shot only penetrated 8in. and broke into small pieces, leaving the plate uninjured practically, "not a single crack being developed." The second shot only penetrated 1in. deeper, and broke into many pieces as before. "The plate was accepted by the Government as exceeding the official requirements, and carried with it the acceptance of the entire lot of which it was the sample, namely, 660 tons."

The differences between these two accounts are indeed startling, so much so as to shake faith in the reports of American trials, we fear. We need hardly point out that the writers are obviously interested on opposite sides. He of August 2nd writes as an eye-witness, but he is reckless in his figures. His calculated energies are 1410 and 2370 foot-tons. Mr. Fox makes them 12,660 and 21,880 foot-tons. We make them 12,650 and 21,860, practically agreeing with Mr. Fox. Then the eye-witness evidently rejoiced to see one shot "burrow" into the plate, and the other bounding into the woods, after riddling everything. Very naturally Harvey's agents are much shocked at the character, to say nothing of the tone, of this report. Evidently the contradiction—for correction is too mild a word—which they have now given us is the result of inquiry. We cannot, however, say that the case is disposed of. We cannot conceive that the "lie circumstantial," as Shakespeare calls it, can be told with the vigour here displayed. We think it is necessary to suspend judgment for a time, and wait for further explanation. The sense of wrong has, we think, made Mr. Fox protest too much. The plate, according to him, started by being so defective that it was unfit for test. Nevertheless it was tested, and behaved so triumphantly, that 660 tons, "*of which it was the sample*," were accepted. Is not this a little like the woman who was sued for breaking a pot, when she pleaded "it was cracked when I got it, it was whole when I returned it, and besides, I never had it at all?" We calculate the first round as a very mild test on either set of figures. The second was a severe one; but with an inch difference in reported thickness of plate, and results all in hopeless contradiction, it is idle to proceed further.

Finally, we would suggest some curious conclusions that follow from comparing recent American with Russian and other continental trials of treated plates. At Texel, in 1893, projectiles entered more deeply into a treated than into an untreated plate until the velocity exceeded 1600ft., when they broke against the treated faces. At Gavre in April, 1893, a projectile broke against a 10·54in. Harveyised plate, at 1901ft. velocity, with only 6·6in. penetration; but when the velocity reached 2132 foot-seconds, the shot perforated without fracture, passing on 200 yards; and again, at 2296 foot-seconds it again perforated, and ricochetted about 2000 yards beyond the target unbroken.

So far as these experiments go, they suggest that the treated face has power to break the projectile, and so destroy its effect, between 1600 and perhaps 2000 foot-seconds velocity, but fails both below and above that range of velocities; and in each case there was more than one example. On the other hand, Russian recent trials show that by means of some device—probably a steel false point—the sudden action of fracture of the treated surface of the plate may be prevented, and perforation obtained. All this looks bad for Harvey; nevertheless, we should not take it too seriously. The results of other experiments do not agree with these. The range of velocity at which the hard face acts includes nearly all the serious velocities on service; and the Russian secret shot have yet to be shown to be a device available for service conditions. We do not know enough of them yet to say much. Certainly it must be, under most conditions, a very great advantage to give a plate a very hard face, unless we greatly injure its mass by so doing. All that we should argue from the above is that there is sufficient ground for making certain trials with treated plates, especially with a view to service conditions. It is probable that the direct attack to which they have nearly always been subjected does not really show the full powers that they possess.

◆◆◆

### GLASGOW CORPORATION TRAMWAYS.

The most recent and also one of the most important of Glasgow's municipal undertakings, the acquisition of the city tramways, has now been fairly ended, and after fully a month's working it is pretty clear that from a passengers' point of view the new order of things, allowing for some inevitable shortcomings, is an improvement on the old. When some few years ago it was decided to make the working of the tramways a Corporation department on the expiry of the old company's lease at the end of June, 1894, the citizens were promised great things in the way of mechanical traction. The tramway committee discussed electric, steam, gas, cable, and other systems of haulage enthusiastically, and visited almost every city in the world where anything bearing on the question could be seen and reported upon. Ultimately, however, the committee found it impossible to decide upon any mechanical scheme of traction, and moreover if such had been fixed on there were very considerable difficulties in the way of putting it into practice until the Corporation obtained possession of the lines. Accordingly negotiations were opened with the tramway company for the purchase of existing depôts, stables, and the stud of horses. The negotiations failed, and the Corporation found itself face to face with the necessity of providing within a comparatively limited period, buildings, cars, horses, and working staff—in short, everything necessary for the system except the street rails. Under the circumstances it is creditable to all concerned that before the first day of last month nine large depôts had been erected in different parts of the city, and some 3000 horses bought and partially trained for their trying work. Over a hundred cars of improved pattern, out of a total requirement of about 250, had also been obtained, and a complete staff of servants organised. These preparations involved a direct expenditure of over £300,000. Mechanical haulage, though shelved for the time by the necessities of the situation, has not been forgotten, and in several of the depôts the construction arrangements have been carried out with a view to the future accommodation of winding machinery for cable traction. Probably the first experiment will be made on the great east and west thoroughfare formed of Gallowgate, Irongate, Argyll-street, and Dumbarton-road, with a total length of some seven miles. Recently, when the roadway in Argyll-street was relaid after the operations of the Central Railway Company, boxes for the accommodation of cables and pulleys were placed in position. It has been tentatively arranged that the motive power for this route will be located at Kelvinhaugh, where a large depôt has been built. A slow-running cable will be carried to the eastern extremity of the city, and westward from the power station there will be a fast-running cable carried to Whiteinch, the vehicular traffic on the latter section being much less dense than to the east of Kelvinhaugh. Meanwhile the number of horse cars is being gradually increased; but they have by no means the monopoly of the passenger traffic enjoyed by their predecessors, the old tramway company keeping up a formidable rivalry by a large service of well-appointed omnibuses.

### THE COALFIELD UNDER THE SETTLEMENT.

Opinions differ very much with regard to the probable working of the coal settlement. On one point there is pretty general agreement. It is this:—That the arrangement will "hit" the old collieries—that is, the pits which are much worked out—very hard, but that it will suit those collieries which are only partially worked, or being opened out. The coal trade cannot possibly be brisk until business is good enough to overtake something like the full output. On the other hand, the colliers cannot have full employment for that and another reason, the other reason being that there are more miners than mines. The tendency in the country districts is for the farm labourers, and all dependent upon agriculture, to abandon their callings and go down the pits, or compete in the crowded centres for such occupation as is to be had. All this, of course, is bad for the country, and bad for the town. It depopulates the rural hamlets, and adds to the hosts of unemployed in the large towns. Farm labourers leave the land for which they are fitted, to scramble with their brethren in the town, where they are not wanted. It is in the coal industry where their presence is most keenly felt. That is one of the great difficulties of the miners' leaders. These gentlemen have tried various ways of getting rid of what they called "the unskilled labour." One drastic remedy, compelling them to come into the Union, has proved powerless. The labourer has got his foot down the pit, and he keeps it there. He resisted for a time all efforts to coerce him into the Miners' Union, but finding that if he did not join the ranks life in the colliery villages would be intolerable, in consequence of the merciless boycott operated against him, he made up his mind to join the Union, and to-day the whole of the Yorkshire, Derbyshire, and Central England colliers may be set down as Unionists. That result, however, while it has given Mr. Pickard and others a formidable organisation with which to work, has left the congested labour market where it was. In fact, it has made the difficulty more deep-rooted, for the recent accessions to the mining ranks from the farm lands are now formally recognised as miners. It is calculated that there are at this moment 200,000 more miners than are required. This of necessity diminishes employment all round. There is no mystery in the cause why the country worker sought a living in the colliery. The great wages agitation, which gave the miners 40 per cent. advances, proved too much for friend Hodge. He was human enough to prefer making, in a couple of days, sufficient to keep him comfortably for the week, rather than by labouring six days for the beggarly allowance the farmer could afford him. Mr. Pickard, in his successful advance of wages, has thus succeeded over much. As he cannot get rid of his surplus labour, his only resource is to try to reduce the hours of working, to spread it more equally over the whole of the mining community. Hence the compulsory Eight Hours-a-day Bill. The coalowners admit that this will largely diminish the output of individual colliers, and necessitate the employment of more men in the pits; but at the same time, it will increase the cost of production, and thus it will tell against the revival of trade, upon which the future of the industry chiefly depends. In this way the eight hours policy will practically take away with the left hand what it gives with the right. It is bound to furnish another evidence of the folly of those who seek to govern the conditions of working, as one of them put it in Derbyshire a short time ago, "altogether irrespective of the law of supply and demand." There is no over-riding these natural laws. Still there are some people who think it can be done, yet all attempts at experimental legislation, such as this contribution to the doctrine of idleness, are foredoomed to failure.

### THE NEW STANDEDGE RAILWAY TUNNEL.

No greater contrast was in all probability ever presented with regard to civil engineering old and new than that furnished by the opening of the new double railway tunnel through the Standedge Hills, which has been used for the first time during the present week. Four tunnels now pierce the well-known Standedge Hills, which are met with on the London and North-Western Railway route from Liverpool and Manchester to Huddersfield. It may not be generally known that it is one hundred years since the canal tunnel was commenced, viz., in 1794. The tunnel, which is 3 miles and 17½ yards in length, took seventeen years to construct, whilst the second railway tunnel was finished in two years, and the double-line tunnel just opened has been constructed in four years. The extent of the whole of the undertakings is very great. The cost of constructing the canal tunnel, which was opened in 1811, was about £56,000. The tunnel is about 656ft. above the level of the sea. It is 8ft. wide and 16ft. high, one half being under water. During its progress there was serious loss of life. The first of the railway tunnels, which is 3 miles and 60 yards long, was commenced on the 1st November, 1846, and was completed on the 1st November, 1848. The gunpowder used for blasting and other purposes cost £5131, fuses £698, and candles £3618. No fewer than 1953 men were employed on the work at one time. There were nine fatal accidents during the progress of the work, which entailed an outlay of £201,608 12s. 3d. Mr. Nicholson, who constructed the well-known Woodhead tunnel, was the contractor. The second railway tunnel was commenced in the middle of April, 1868, and was completed in the middle of October, 1870, about six months earlier than was expected. Its exact length is 5435 yards, or one yard shorter than its twin tunnel. The total quantity of brickwork built was 52,156 cubic yards, the total bricks used being 16,831,149, the weight of which amounted to 68,000 tons. The total cost of the tunnel was stated at time to be £120,000. The last tunnel was commenced on the 5th of August, 1890, when the first sod was cut, and so far has the work progressed, that Major Yorke, Government Inspector of Railways, has already inspected the undertaking, and has given his certificate for the opening of the tunnel and works. The material required and the engineering skill have been provided by the company, and it carried out the work entirely, excepting since February, 1893, as regards labour, which was provided by Messrs. Williams, Lee, and Thomas, who up to that date had been foremen in the different departments of the work.

## GERMAN MACHINERY AT THE ANTWERP EXHIBITION.

(*From our Special Commissioner.*)

Several small machines for special purposes are exhibited by Messrs. Goebel and Co., of Darmstadt. One of these is an automatic railway ticket printer. The tickets are in a shaft to the right of the machine, from which they are automatically pushed forward by a tiny lever, printed on one side, and then by the same lever pushed on till they enter a slot in a brass wheel. As soon as this wheel has made half a turn, a catch on the opposite side withdraws the ticket, and brings it under the press by which it is printed on the other side. It is then stamped at each end with a consecutive number, and falls into a shaft on the left. The machine is driven by hand; the inking cylinders for the three printings work at right angles to the travel of the tickets. The whole apparatus is well made and is very compact.
